The Past, Present and Future Treatment of Homoeopathy, Eclecticism, and Kindred Delusions which may hereafter arise in the Medical Profession, as viewed from the Standpoints of the History of Medicine and of Personal Experience. By Henry I. Bowditch, A.M., M.D., Harv., formerly Professor of Clinical Medicine in the Harvard Medical School; Ex-Secretary and Ex-President of the American Medical Association, etc. Boston: Cupples, Upham & Co. 1887.

## Lecture.

ON THE PHYSIOLOGY OF EXERCISE.<sup>1</sup>

BY EDWARD MUSSEY HARTWELL, PH.D., M.D.,  
Associate in Physical Training, in the Johns Hopkins University, Baltimore.

ONE of the principal obstacles to the success of any comprehensive effort to make physical training an integral factor in the education of American youth, is found in the very general misapprehension as to what physical education is, and what its effects are. If the teachings of modern physiology and psychology in regard to the functions of the muscular and nervous systems of the human body were apprehended, even by those classes which we are wont to call educated, it would be a comparatively easy matter to secure the votes and appropriations necessary for the adoption or trial of rational and approved systems of physical exercise.

The fundamental and essential characteristics of exercise are so generally misstated and its proper effects so frequently overlooked, that I have chosen the physiology of exercise as my theme. I cannot hope to present a complete and satisfactory theory of exercise, but I may be able to point out the situation of quarries whither we may repair with profit, for the foundation-stones on which such a theory should be based.

Exercise is so comprehensive and elastic a term, when taken in its general sense, that it may easily be made to cover a multitude of actions, and some sins. The word is so nearly synonymous with practice that it has come to be used oftenest by those who devote themselves to preaching on conduct, on education, or on health. One need not make lengthy or frequent excursions into the domains of theology, of pedagogics or of hygiene, to discover that the meanings of exercise are many and mixed. The casual reader will hardly be struck by the points of resemblance between the exercises made use of by the Greek athlete and the Roman gladiator in preparation for their contests, and the exercises ordained for the training of catechumens and of aspirants for canonization. To the ancient Puritan a week-day sermon was a delightful "exercise," while most of his less serious contemporaries held that shooting, hunting, and riding "which be martial exercises," were the only kinds of exercise proper for gentlemen. At first sight there appears to be no common element in such exercises as the foregoing, and those which our modern teachers of French, of pugilism, and the piano, are accustomed to set their pupils, unless it be the exercise of patience. Still, speaking broadly, it is possible to find in all the secondary meanings of the word, some trace of its primary signification; namely, a repeated action for the sake of training or practice.

It is interesting to note that our word exercise and *exercitus*, the Latin word for the body of best-trained men in the State, the army, are derived from the same verb *exerceo*. The Greek synonym for *exerceo* is *asno* and meant originally to work raw material. In classic times it meant to exercise, to train in the strict athletic or gymnastic sense; later, in the early

days of the Church, it signified to discipline the flesh, to mortify the body, and to it in this sense the English word *ascetic* owes its origin and present meaning. The original *ascetic* was simply an industrious and careful gymnast or athlete.

Our universal friend, the average man of to-day, is theoretically in favor of exercise. "Exercise," you frequently hear him say, "does a man good." The average woman has not attained to the same degree of certitude. If you ask the average man to define his notions of the good which exercise does, he will probably indulge in cloudy generalities concerning its influence in realizing the *mens sana in corpore sano* ideal. It is astonishing what an amount of service that line of pagan Latin has done in confusing thought and preventing inquiry as to the nature of exercise. Press the average man a little to abandon the general and become specific, and you may learn that muscular exercise is particularly good for opening the pores; for cleansing the blood; for quickening the spirits; for getting up one's muscle; and that it is above all valuable for enabling the rising generation to work off its superfluous animal spirits. Every such alleged advantage of exercise is vague or meaningless in the light of our present knowledge. The physiological terminology and ideas of the average man are seldom so recent as the revival of learning, and in many instances antedate the Christian era. The facts that we are in search of have not been quarried on the windy heights of hortatory literature or in the fat meadows of the common mind. If they have been brought to light anywhere it is in fields where physiologists and physicians have been digging so profitably during the last two hundred years.

The best comprehensive definition of exercise that has come under my notice is that given by Du Bois Reymond, Professor of Physiology in the University of Berlin. "By exercise, we commonly understand," he says, "the frequent repetition of a more or less complicated action of the body with the coöperation of the mind, or of an action of the mind alone, for the purpose of being able to perform it better." Practically all human actions are comprised under the two heads of this definition of exercise. Bodily actions demand our first consideration, since without them mental power, artistic feeling, and spiritual insight cannot be made to answer any earthly purpose.

It is far easier to understate than to exaggerate the part which muscular actions play in human life. Imagine the condition of a man perfectly formed, generously endowed, and in his prime, whose single lack should be that sensible, warm motion that has its seat in the muscular tissue. The position of a fly in amber would be lively and preferable to the isolation of such a man. Of course he could not "do business"; but he could think and fear and hope. He must face the future, lying like a log in whatever position he may happen to fall. His face will be absolutely destitute of expression, and his eyes fixed under closed lids. He can neither smile nor weep. His hunger cannot be appeased, nor his thirst slaked. His heart may "burn within him," but it shall not pump blood; so that he will be pulseless as well as breathless and bereft of speech. Unable to stir the tip of a finger or to raise a hair; he will be powerless to express his thought or aspiration, or to impress his conceptions or wishes upon any creature. In short, such a man would be an incorruptible cadaver. Spirit we might not call

<sup>1</sup>This paper, originally given as an address before the American Association for the Advancement of Physical Education, at Brooklyn, New York, November 26th, 1886, has been amplified and re-written since, and was delivered, in substantially its present form, as a Hopkins Hall Lecture, in Baltimore, February 18, 1887.

him, in face of the belief that ghosts are privileged to take nightly walks.

Without muscular tissue, then, we cannot live or move. Its importance to the body is also to be inferred from its mass and weight. Nearly, if not quite, one-half of the body, by weight, is made up of muscular tissue. In it is contained one-quarter of the blood; and by it, fully one-fourth of the energy stored up in the body is turned into work. This tissue consists of fibres which are, for the most part, collected into the distinct organs, which we call muscles. The muscles of the lower animals are familiarly known to us as lean meat; our own have been, at various times, stigmatized as fleshy members. All muscle-fibres are endowed with contractility, by virtue of which they shorten when acted upon by certain agents, termed stimuli.

A large class of human muscles are stimulated by the action of the will, and are, therefore, called voluntary, though some of them habitually, and all at times, respond to other stimuli as well. There are more than five hundred muscles in the human body which are under control of the will. They are mostly arranged in pairs, as, for instance, the muscles of the two hands are alike in number, and identical in form and function. Muscles which do not respond to volitional stimuli are termed involuntary. They are found in the walls of bloodvessels, in the intestinal canal, and other organs.

When examined microscopically, voluntary muscle-fibres show certain faint cross-lines or striae, and are, therefore, often called striated or striped muscle. Similarly, involuntary muscle is called smooth or plain muscle-tissue, because its fibres are destitute of striae. The heart, though an involuntary muscle, is made up of striped fibres, intermediate in character between the sorts named. For our present purpose, it is best to confine our attention wholly to muscles of the voluntary sort.

A freshly-dissected muscle of one of the higher animals presents a smooth surface, rounded outlines, and a glistening appearance. It is usually red in color, though it may be pale or colorless. It is usually distinguishable into three well-marked parts, namely, a soft, red, contractile, central portion, termed the belly, which tapers towards each end; and its two terminal tendons, which are dense, white, inelastic cords, whose function is to connect the muscle with its points of attachment. The surface of the fleshy portion of the muscle is covered by a smooth, glistening sheath of connective tissue. Inward prolongations of this sheath pass into the substance of the muscle, and divide it into bundles of fibres, technically called fasciculi or packets. Each fasciculus consists of a number of fibres running parallel to each other. The fibres are separated from one another by connective tissue, just as the fasciculi are. The muscle-fibre is the ultimate and essential element of muscular tissue. Each fibre consists of a soft, contractile, semi-fluid substance, contained in a tubular sheath — the sarcolemma, the word means flesh-skin — which is transparent, tough, and elastic. Fibres vary in diameter from  $\frac{1}{100}$  to  $\frac{1}{10}$  of an inch, and are seldom longer than  $1\frac{1}{2}$  inches. These fibres are arranged in linear series, and do not intercalate with each other. The amount of shortening in a contracting muscle is equal to the summated contractions of its individual fibres.

It may aid you to picture to yourselves the struc-

ral features of muscles, to liken the ultimate muscle-fibre or cell to a single sausage. The sarcolemma would then correspond to the sausage-skin, and the contractile contents of the sarcolemma to the sausage-stuff. The muscular fasciculus would represent many parallel rows of sausages, placed end to end, and bound together and invested by a tough, elastic membrane, so as to form a kind of rope. The muscle, as a whole, would stand for a collection of such ropes, lying parallel to one another, in the form of a large bundle, widest in its middle region, and tapering towards each end. If to each end of the packet of sausages you attach a dense cord, made up of inelastic fibres, you would complete a structure which should be roughly comparable with some of the typical single muscles, so far as the mere arrangement of their muscular tissue is concerned.

If we lay bare a muscle in a living animal, we may cause it to contract before our eyes, either by bringing a heated body close to it; by giving it a slight tap; by applying certain chemical substances to it, such as ammonia, lime-water, or common salt; or by giving it an electric shock. The details of muscle-physiology have been worked out chiefly through the study of cold-blooded animals, since their tissues are longer-lived, and suffer less injury from the manipulation required in making experiments than do those of warm-blooded animals, like the dog and cat. But a sufficient number of observations have been made upon the higher animals, including man, to warrant the belief that their muscles act in essentially the same way as the muscles of frogs and turtles.

When a muscle outside the body is acted upon suddenly by an appropriate stimulus, it quickly shortens; and then, if it has been loaded with a weight, rapidly returns to its former length. A weighted muscle outside the body, or one in the body, which acts against resistance, does work every time it contracts. Its work is chiefly of the sort which physicists have named mechanical work, and is equal to the product obtained by multiplying the weight lifted by the distance through which it is lifted against the force of gravity. Its measure is expressed in foot-pounds. A muscle with no weight attached does no "work" when it contracts; nor does it do any work if it is loaded with a weight too heavy for it to lift. Of two muscles equal in cross-section, the longer can do more work; whereas, if two muscles are of equal length, that which contains the greater number of parallel fibres will do more work than the other. It is estimated that a square-centimetre of human muscle can just lift a little more than twenty pounds. Muscles are somewhat elastic; and, in the body, are slightly over stretched.

But a single muscle is a more complicated structure than you would suppose from my description of it; and, under normal conditions, is excited to contract by nervous stimuli, and not by any of those which have been mentioned. It was necessary to mention them, as showing what is termed the independent irritability of muscle. Besides its contractile substance, its tendon, and the sheaths which invest its fasciculi and fibres, every muscle has bloodvessels and nerves, whose functions must be considered before we can arrive at a clear understanding of muscular exercise. Fresh blood is supplied to the muscle-substance by the heart, through its arteries, and the fine network of arterial capillaries formed by the minute subdivision of the

arteries. As elsewhere in the body, the arterial capillaries open into, and are continuous with, the venous capillaries, which, becoming united into larger and larger vessels, form the veins of the muscle, or the channels by which the blood is returned to the heart from the muscle. Muscle-arteries, and veins usually lie alongside of each other in the connective tissue which surrounds the fasciculi, while their capillaries form a fine meshwork of vessels, lying between and upon the muscle-fibres, but without penetrating the sarcolemma of any fibre. The walls of the capillaries are permeable to lymph, as the fluid portion of the blood is called. The fibres are, therefore, bathed in lymph, and derive their food-supply from it by absorption through their tubular sheaths.

Before considering the part which nervous stimuli play in muscular contraction, we must glance at the structure and functions of the elements which make up the nervous system. Nerve tissue like muscular tissue is irritable, in that it is responsive to stimuli, but it is irritable in a vastly higher degree; unlike muscular tissue it is in nowise contractile. The elements of the nervous system take the form either of nerve fibres, or of nerve cells. An aggregation of nerve cells constitutes a nerve ganglion. The fibres serve for the conduction of stimuli and connect central nervous organs, such as parts of the brain and spinal cord, with organs at the periphery of the body, such as the eye and the hand. Nerve cells not only transmit impulses, but also act as physiological centres for regulating motion, sensation, nutrition, secretion, etc. Nerve fibres are known as afferent when they conduct impulses toward nerve centres, and as efferent when they transmit impulses outwards from nerve centres. Since stimuli which are transmitted centrifugally from organs in the periphery give rise to sensations, afferent nerves are very commonly called sensory; and since impulses which are transmitted centrifugally to the motor organs from the centres give rise to motion, efferent nerves are called motor nerves. A single instance will serve to illustrate the use of sensory and motor fibres. If a fly alight on my forehead the sensory fibres of the skin are stimulated. Afferent impulses then travel up the fibres to centres within the brain. As a result of the slight shock imparted to the nerve cells, that part of me which is in communication with that group of cells is rendered conscious of a new sensation, and I feel disturbed. If I am sufficiently disturbed to feel irritated, my will causes the centre to send efferent impulses along motor nerves, which pass to the muscles of my arm and hand, and my hand is moved to brush off the fly, which, being amply furnished with sensory and motor organs of his own, usually retires in glee or terror, as the case may be, before my hand can reach him.

From their appearance nerve fibres are divided into white fibres and gray fibres; and from their structure the white fibres are termed medullated, or fibres with a pith; and gray fibres are called non-medullated, or fibres without a pith. The medullated fibres are the more highly developed of the two. The essential, conducting part is in each kind of fibre known as the axis-cylinder. It consists of a very fine cylindrical thread or strand of fibrils transparent semi-fluid, and highly irritable protoplasm, when alive. In medullated fibres the axis-cylinder occupies the central fourth of the fibre. Outside it and surrounding it, just as the wax of a can-

dle surrounds its wick, is the medullary sheath of white substance, and outside of the medullary sheath is another sheath known as the primitive sheath, or neurilemma, which serves as a protection to the parts within. The neurilemma is comparable to the sarcolemma of the muscle fibre. Medullated fibres, which vary in breadth from  $\frac{1}{1000}$  to  $\frac{3}{1000}$  of an inch, are aggregated into bundles termed *funiculi* or ropes, corresponding to muscular fasciculi. The funiculi are enclosed in connective tissue sheaths. An aggregation of funiculi forms a nerve trunk, the "nerve" of ordinary speech. The main difference between non-medullated and medullated fibres is this: the former has no medullary sheath interposed between the neurilemma and the axis-cylinder. The medullary sheath of the latter gives it its white appearance and its name of white fibre.

Nerve cells present too many and too varied forms for description here. Suffice it to say that the simplest forms are roundish in shape; others, oval in shape with prolongations at each end, are termed bipolar; others are irregular in shape with many branches or processes. All of them contain living and highly irritable protoplasm of a granular gray appearance, usually enclosed by a sheath or cell-wall. It only concerns us to remember that some of the processes serve to connect cells with other cells, and that the axis-cylinders of nerve fibres are direct and unbranched prolongations of the irritable cell substance.

To return to the motor nerves of the muscles. The nerve fibres found in the muscles are of the white or medullated sort. The motor nerve belonging to a muscle usually enters the muscle at its middle point. It then divides and subdivides into so many branches that every muscular fibre receives a nerve fibre. Where the nerve fibre pierces the sarcolemma the axis-cylinder spreads out, forming an eminence of protoplasm within the sarcolemma. This eminence is known as the "motorial-end plate." The branches of the axis-cylinder traverse this end-plate, and subdivide into fibrils which penetrate the contractile substance of the fibre. Only the axis-cylinder of the nerve passes within the sarcolemma; since the outer sheath of the nerve fibre coalesces with the sarcolemma itself, and the medullary sheath ends at the sarcolemma.

We have, then, the contractile substance of the muscle fibre connected with the irritable stimulus-generating and transmitting substance of the central nerve cell, the connecting link being the axial fibre of the motor nerve, which is simply a portion of the nerve cell's contents long drawn out, in the form of a strand, until it reaches the muscle fibre, where it spreads out to form the end-plate, and then subdivides into fibrils which penetrate the muscle substance. What is true of a single muscle fibre is true of all the fibres in a given muscle; and what is true of one voluntary muscle is true of the entire five hundred. Voluntary muscles have sensory as well as motor fibres. They are the channels for the impulses which give rise to muscular sensibility, and are connected with centrally situated nerve cells which minister to our muscle sense. The sense, that is, which keeps us informed concerning the condition of the muscles, and the extent to which they are contracted.

A single muscle then is to be considered as an aggregation of a vast number of contractile fibres, arranged in myriads of linear series which in turn are

gathered into bundles, all of which, along with their accompanying nerve fibres and nutrient bloodvessels are supported and bound together by means of elastic connective tissue. The muscle, so made up, has its own special sheath, and is bound by its inelastic tendons to the bones which it is set apart to set in motion. It was stated that muscular contractions could be brought about through the direct application of chemical, thermal, mechanical, or electrical stimuli to the muscle itself. If the nerve of a muscle be excited by pinching it, by beating it, by applying certain chemicals to it, or by electrifying it, the muscle is indirectly stimulated to contract by means of the motor impulses discharged into it through its motorial-end plate. The motor nerve may be stimulated at any part of its course. Again, the muscle may be set in action through stimulation of the centres whence its nerve fibres emerge. The same stimuli have no effect upon the muscle when applied to the centre, if the path between the centre and the muscle have been blocked by severing or compressing the nerve. Such severance or compression may take place in the body as the result of certain diseased conditions of the nerve, or the parts adjacent. Motor paralysis is then the result.

The effects of exercise upon a muscle and the parts connected with it next demand our attention. It must suffice merely to note the most important of them. Immediately a muscle begins working, under whatever stimulus, the blood-stream passing through it becomes changed, both in respect of quantity and quality. The arterial twigs which ramify within it dilate; more blood is poured into the capillaries surrounding its fibres; and more blood flows through the veins from the muscle.

The blood which enters the muscle is bright red in color, rich in oxygen, and poor in carbonic acid. That which leaves it is dark blue in color and of a higher temperature; richer in carbonic acid, and poorer in oxygen; and contains various products, due to the chemical changes which take place in the food-material supplied to the muscle-substance, and in the muscle-substance itself. If the supply of arterial blood to a muscle is cut off or diminished, its irritability is lowered, that is, a stronger stimulus is necessary to make it contract. The same result follows, also, if it is fed with blood deprived of oxygen, or otherwise poisoned; or if the muscle-vein is tied, and the waste-products, normally drained off through the veins, are retained within the muscle. The irritability of a muscle is also lowered by prolonged stimulation, even when its in-going and out-going blood streams are unobstructed. If these disturbed conditions do not persist until the muscle-fibres pass into the condition known as death-stiffening; the irritability of the muscle may be restored, either by sending fresh blood through it, by sending a stream of some indifferent fluid through it, or by ceasing to stimulate it.

In the first case, restoration is brought about through the renewal of its supply of food-material and oxygen; in the second, by clearing out the noxious waste-products; and in the third, by allowing it to rest awhile. These, then, are the main conditions demanded for the health of a working muscle: A full supply of proper food and oxygen; unimpeded and sufficient drainage; and rest at due intervals. Given these three conditions in the body and exercise of a muscle causes it to increase in size and weight, through the increased

size and number of its fibres. Furthermore, a working muscle differs from a resting muscle in that it is appreciably hotter; by the presence of a low murmur, called the muscle-sound, which is caused by the more rapid vibration of the particles of the slightly over-stretched fibres; and on account of certain electrical peculiarities which it presents.

A muscle habituated to so exercise can do more work, and do it better, than an unexercised muscle, and for two reasons. Exercise makes the muscle larger, harder, and stronger, improving it simply as a tool in all its structure; and secondly, the muscle responds more quickly and completely to the stimuli which stir it up to work. In other words, the muscle becomes more obedient to its stimulators, the nerve-centres, through its better acquaintance with them. A muscle, then, is a neuro-muscular machine for developing power, for transforming the potential energy stored up in its substance, and the blood brought to it, into one or another form of the energy of motion.

If we consider a single muscle as a mechanism for developing energy of motion, it may be compared to a peculiarly-arranged collection of cartridges loaded with powder, and connected by wires with a series of electrical batteries. Each muscle-fibre would, in that case, stand for a single cartridge, the shell of the cartridge being represented by the sarcolemma; the charge of powder by the chemical components of the contractile substance; the wire from the battery by the motor nerve-fibre, and the cells of the battery by the cells of the nerve-centre; and the electric current by the nervous stimulus, which, passing along the axis-cylinder through the nerve-plate into the contractile substance, gives rise to the phenomena which attend a muscular contraction.

When a cartridge is exploded, chemical actions take place, which result in the sudden formation of gas, accompanied by the development of light, heat, and sound, and the production of a residue of smoke and ashes. If the cartridge-shell be tight and tough, the motion of the molecules of the suddenly-formed gas will be communicated to its particles, and the shell be shaken or moved from its position. By varying the construction and arrangement of the cartridges, we may cause the liberated energy of the explosive to set projectiles in motion, to rend rocks, or to move parts of mountains. The results of chemical explosions in the muscle-cartridges are less violent than those above noted, but they are sufficiently similar and well marked to be called parallel to them. The potential energy of the muscle-fibres is transformed into the energy of motion, through the decomposition of the chemically-unstable contents of the sarcolemma. Heat, sound, electrical changes, and mechanical motion are involved. The mechanical arrangement of the parts of the muscle are such that the total motion of the mass of its fibres is communicated, by the tendons of the muscle, to the parts of the body with which it is connected. So long as the muscle-fibres are properly nourished, and not too severely stimulated, the muscle-cartridges may be said to reload and maintain themselves in a state of readiness to go off on the receipt of stimuli from the central battery.

Muscles are more perfect power-machines than are steam-engines and rifled cannon, not only because they develop more work out of the energy stored up in the substances on which their activity depends, but also because they are distinguished from all machines of

human manufacture by the fact that they are self-improving machines, that is to say, they become tougher and stronger as structures through exercise, and, at the same time, more capable and adaptable functionally. Growth or increase in the size and number of its structural elements and development, or increased facility in its functional activity, are the main effects of exercise in the case of a single muscle. The same is true of the muscular system as a whole. Exercise enlarges and strengthens it on the one hand, and renders it more responsive and discriminative, as regards stimuli, on the other. The body, as a whole, is a machine in which the potential energy of organized material is transformed into the work which we see manifested in motion, animal heat, and the chemical actions involved in nutritive, secretory, and excretory processes. It is estimated that the tissue-changes of which a human adult body, weighing one hundred and forty pounds, is normally the seat, involve the transformation of more than a ton of material in the course of a year. Muscular activity is one of the chief agents in promoting wholesome tissue-changes in all the bodily organs, and in determining the normal growth and development of the organism as a whole.

It is beside my purpose to dwell at length upon the effects which exercise of the muscular system exerts upon the other systems of bodily organs. At the same time, the general effects of exercise are too important to be passed over without notice. The following account of them, given by Dr. G. Wilson, a well-known English writer on hygiene, may here suffice:

"Not only are the muscles themselves benefited by exercise," he says, "because they are brought into action, but, by their action, they increase the rapidity of the onward flow of the blood to the heart; the heart itself beats more vigorously; a larger quantity of blood is sent through the lungs; more oxygen is absorbed; a greater quantity of heat is engendered; and the skin and the other organs of secretion are brought into action, to get rid of the superfluous heat and the products of combustion. Thus the heart, lungs, skin, and other organs of the body are brought into more active play by muscular activity; the brain and nervous system are invigorated; the digestion is improved; and the whole machinery of the body is kept in efficient working order. On the other hand, through want of sufficient bodily exercise, the constituents of the food which pass into the blood are not sufficiently oxidized; effete products accumulate; the muscles become flabby or fat; the digestion is disordered; the nervous system becomes enfeebled; the function of secretion is impaired; and ill health or disease ensues. Indeed, it may be laid down as a rule that, other things being equal, those who take a sufficient amount of exercise in the open air, or are employed in active outdoor labor, will enjoy the best health and live the longest; and this is borne out by the statistics of the Registrar-General, which clearly prove that gamekeepers, farmers, and agricultural laborers are among the healthiest classes of the community."

Dr. Wilson holds that, as a rule, the amount of exercise required by a man of average height and weight is equivalent to a daily walk of eight or nine miles along a level road. "This rule, of course," he adds, "only applies to a man in the prime of life, for growing lads or women, who by the way, are rated as physically equal to lads of sixteen, the amount of ex-

ercise required would be somewhat less." This rule is for the average adult Englishman, whose height may be set at 5 feet, 6.6 inches, with a corresponding weight of 137 pounds. The height of the average American man is 5 feet 7.69 inches, and his weight is 141.93 pounds. I incline to believe that a growing boy needs more exercise than a mature man, since the boy needs exercise to promote growth quite as much if not more than to keep his bodily machinery in repair and smooth working order.

If we bear in mind that next, perhaps, to an adequate supply of proper food, nothing so promotes the normal growth and development of the body, as well regulated muscular activity; it is interesting to compare the children of different classes of the population as regards their height and weight. Although Dr. Bowditch, Professor of Physiology in the Harvard Medical School, and others in America have made valuable observations in this field, still, as more interest has been shown in this kind of investigation in England, where classes as such are more easily studied than with us, and the value of exercise, especially that derived from athletic sports, has been longer and more generally recognized, I shall bring forward, here, only English results for the most part.

The very complete and valuable tables published by Dr. Charles Roberts, of London, touching the mean height and weight and annual rate of increase in the case of some 7,800 boys and men, between ten and thirty years of age, belonging to the artisan class on the one hand, and 7,700 males between ten and thirty, belonging to the most favored class on the other, show that the mean height of the artisan class is for the whole period about three inches less than the mean height of those belonging to the most favored class. In the latter class public school boys, military and naval cadets, university and medical students were included. Although the inferior stature of artisans may be to some extent an inherited characteristic, it is held to be chiefly due to "the continuous operation of various conditions of life which retard and arrest growth, and which are most influential when growth is most rapid." Among the conditions so operating, "scanty feeding and wearing toil" as contrasted with "abundant nourishment and moderate exercise" occupy a prominent place. These tables also show a progressive gain as regards weight, on the part of the favored over the industrial class, both absolutely and in relation to height throughout the entire period under review. At the age of ten years the boys of the most favored class exceed the artisan's sons by one pound in weight; at twelve their excess in weight has increased to four pounds, and at thirteen they are ten pounds ahead. At the age of twenty, well-to-do English youths have a mean weight of eighteen pounds greater than that of handicraftsmen of the same age living in large towns. As regards chest-girth, and well directed exercise tells directly upon chest capacity, the most favored class is clearly superior to the industrial, which superiority is progressively increased until nearly adult life. In another of Dr. Roberts's tables it is shown that the sons of professional men living in the country exceed town boys of the same class by about an inch as regards height, at all ages between ten and twenty, and as regards weight by an amount varying from one to seven pounds. It also appears that the sons of soldiers, policemen, messengers and the like, are from one to four inches less in stature

and from four to thirteen pounds less in weight than boys of the same age whose fathers are devoted to intellectual pursuits; that the sons of artisans and factory operatives are the shortest and lightest of all youthful Britons, with the exception of idiots and imbeciles, of the same age, who have a mean height of an inch less even than youths of the artisan class. American boys seem to be a little taller and a little heavier than their English cousins of the same age and class.

Dr. Boulton, another English student of anthropometry, made observations extending over ten years on a certain group of children, all of whom were healthy, and the offspring of well-to-do parents. Dr. Boulton finds that "average English children brought up under favorable circumstances grow from two to three inches a year. A growth of less than two inches or over three should excite apprehension. The former would indicate arrested development. The rate of growth should be regular, and being so prognosticates future good stature." As to weight for height, whether a child grows two, two and a half, or three inches in a year, weight for height should be in each case identically the same, and all healthy children should grow broad in proportion to their height. "Between three and four feet the increase in height should," he says, "be two pounds per inch and, between four and five feet, two and a half pounds per inch. Well nourished children of healthy parents, in favorable surroundings, generally attain these averages. But what of children that fall below the standard? I find there is a seven-pound margin of safety, and that children falling more than seven pounds below this standard are devoid of reserve of stamina on which to draw, and consequently succumb quickly to many constitutional diseases. This then may be called the preventive medicine margin beyond which lies the dangerous land of cachexia."

Cachexia is a medical term signifying a depraved or lowered state of nutrition or of nutrient activity, in which the power of the tissues to repair injury or to resist inherited tendencies to disease is dangerously diminished. Amongst the best-marked cachexia are the cancerous, the malarious, and the phthisical. There is a condition of mind and body not infrequently seen nowadays in children and youth, especially among females, which is characterized by an irritable, easily overwrought, and unsteady nervous system, arrested muscular development, disordered digestion, and enfeebled powers of assimilation, which might well be called *cachexia scholastica*, since it is largely and sometimes directly brought about by ignorant and foolish parents and teachers who force and cram and overwork the undeveloped brains of children, and at the same time by neglecting or frowning upon their play and exercise, do their best to retard the growth and development which they ought to promote and might regulate.

The late Alexander MacLaren's experience with the first squad of twelve non-commissioned officers sent to him to be qualified as instructors in gymnastics in the British army, may serve to show how systematized and well-directed exercise may be made to influence bodily development in a comparatively short time. The twelve men alluded to ranged between nineteen and twenty-nine years of age, and had seen from two to twelve years' service. At the end of eight months' gymnastic training the increase in the measurements of the men was as follows:

	Weight.	Chest girth.	Fore-arm girth.	Upper-arm girth.
The smallest gain.	5 lbs.	1 inch.	1 inches.	1 inch.
The largest gain.	16 "	5 "	1 1/2 "	1 1/2 "
The average gain.	10 "	2 1/2 "	1 1/4 "	1 1/4 "

"The muscular additions," says MacLaren, "to the arms and shoulders and the expansion of the chest were so great as to have absolutely a ludicrous and embarrassing result, for before the fourth month several of the men could not get into their uniforms, jackets and tunics, without assistance, and when they had got them on they could not get them to meet down the middle by a hand's breadth. In a month more they could not get into them at all, and new clothing had to be procured, pending the arrival of which the men had to go to and from the gymnasium in their great coats."

(To be continued.)

### FIVE CASES OF LARGE VISIBLE PULSATING ARTERY ON THE POSTERIOR WALL OF THE PHARYNX, WITH REMARKS.<sup>1</sup>

BY J. W. FARLOW, M.D., BOSTON.

CASE I. E. N., a girl, thirteen years old, came to me at the Boston Dispensary, complaining of nasal catarrh and enlarged cervical glands; she had also an atrophic pharyngitis. My attention was immediately drawn to two large, pulsating vessels on the back of the pharynx, about quarter of an inch inside the posterior pillar of the fauces, and lying directly beneath the mucous membrane. By slightly depressing the

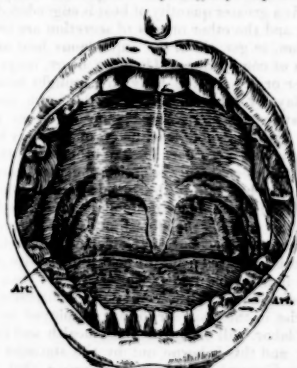

FIG. 1.

tongue the lowest point of the pulsation was easily seen, the upper limit was a little higher than the base of the uvula. The vessels were nearly vertical, and the left one had a more marked pulsation than the right. To the finger the impression was given of an artery fully as large as the radial. Fig. 1 will give

<sup>1</sup> Read at the meeting of the Section for Clinical Medicine, Pathology and Hygiene, of the Suffolk District Medical Society, February 9, 1887.

a very good idea of the vessels. The patient knew nothing of this condition of her pharynx. Thinking that the large cervical glands might, by pressure, be the cause of this pulsation, I watched carefully to see if the vessels diminished in size as the glands grew smaller. But such was not the case. The glands entirely disappeared and the nose much improved, but the pulsation continued as before. I saw her the other day, eighteen months after her first visit, and found no change in the vessels.

CASE II. Mary C., eighteen years old, came to me complaining of nasal catarrh and some atrophic pharyngitis. There was a large, pulsating vessel on the posterior wall of the pharynx on the left side, as in Case I, but none was seen on the right. There were no large cervical glands.

CASE III. Annie M., twenty-three years of age, came to me for post-nasal catarrh. On the back of her pharynx were two large, pulsating arteries, almost an exact counterpart of Case I.

CASE IV. This was a woman about thirty years old, and was seen at the Massachusetts General Hospital, by Drs. F. I. Knight and F. H. Hooper. No notes of the case are at hand, but Dr. Hooper thinks the large vessel was on the back of the pharynx, about half-way between the uvula and the posterior pillar of the fauces on the right side.

CASE V. A little girl, four years old, came to me for nasal catarrh. On the posterior wall of her pharynx on the right side was a large pulsating vessel as in the other cases. The glands of the neck were slightly enlarged. A sister, five and a half years old, has beginning atrophic pharyngitis and rhinitis but no artery visible.

All the other cases seen by me were women, and in all the pharynx was atrophic, in two markedly so, the mucous membrane being thin, dry and shining.

This condition must be very rare, for I find no mention of it in text-books or in the literature of the subject. In my service of five years in the throat-room of the Boston Dispensary, I had never met with a case, and yet my three cases were seen within a week or two of each other, as is often the case with rarities.

In regard to what vessels these are, let us look at the normal blood-supply of the pharynx. The pharynx receives its blood principally from the ascending pharyngeal, a branch of the external carotid and the ascending palatine, a branch of the facial. (See Fig. 2).

Cruveilhier<sup>2</sup> says: "The ascending pharyngeal is the smallest branch of the external carotid. Its calibre is in inverse proportion to that of the palatine branch of the facial. I have seen it as large as the occipital. Its pharyngeal branch sub-divides at the base of the skull into several branches which penetrate the very dense fibrous tissue at the insertion of the pharynx to the occiput. These then turn downward, and terminate in the walls of the eustachian tube and the muscles of the pharynx. In a case of absence of the palatine branch of the facial I have seen the pharyngeal branch very large, supply the tonsil and ramify and lose itself on the veil of the palate."

Sappey<sup>3</sup> says: "The ascending pharyngeal is distinguished from the other branches of the external carotid by its small size and vertical direction."

Gray<sup>4</sup> says: "The largest of the pharyngeal branches of the ascending pharyngeal passes inward, running upon the superior constrictor and sends ramifications to the soft palate, eustachian tube and tonsil, which take the place of the ascending branch of the palatine when that vessel is of small size." With regard to the ascending palatine, Gray says: "It passes up between the stylo-glossus and stylo-pharyngeus to the outer side of the pharynx. After supplying these muscles, the tonsils and eustachian tube, it divides near the levator palati into two branches; one follows the course of the tensor palati and supplies the soft palate and palatine glands. The other passes to the tonsil, which it supplies, anastomosing with the tonsillar artery. The tonsillar branch passes up along side of the pharynx and perforating the superior constrictor, ramifies in the substance of the tonsil and the root of the tongue."

According to the above descriptions it seems as if, in my cases, the vessels were the ascending pharyngeal arteries, from their situation on the superior con-

FIG. 2.

strictor and their vertical direction, and inasmuch as mention is made of the increased size<sup>5</sup> of the vessel when the ascending palatine is small, it is possible that the latter vessels in my cases were unusually small. The atrophy of the mucous membrane allowed the pulsating vessel to be seen more readily.

The surgical importance of these cases is sufficiently evident. In case it were necessary to make an incision in the back of the pharynx, as in retro-pharyngeal abscess, we see how great the risk of an alarming hemorrhage might be. In all cases, where possible, it is advisable to examine with the finger, before operating, to see whether an artery of abnormal size or situation is present.

Dr. Porter<sup>6</sup> relates a case of recurrent hemorrhage from behind the left tonsil, which he thought came from the tonsillar artery or from a branch of the ascending pharyngeal; also a case of hemorrhage from an ulcer on the posterior surface of the soft palate, probably from the same vessels.

<sup>6</sup> Tr. Am. Med. Association, 1882, page 511.

Dr. E. Carroll Morgan, of Washington, D. C., who has recently written a paper on "Hæmorrhage following Uvulotomy," writes me as follows: "Obstinate bleeding following uvulotomy is, in my opinion, often due to the condition your cases so well illustrate. Literary research has surprised me, I confess, and I have now collected seventeen cases of dangerous hæmorrhage after this simple operation. Twelve of these have never been published, and were obtained by personal letters. Strange as it appears, the possibility of an anomalous artery being a factor in the dangerous hæmorrhages which here followed uvulotomy has never been mentioned in connection with reported instances."

These arteries must also be taken into consideration in cases of surgical treatment of the tonsils. Many cases of hæmorrhage following tonsillotomy are reported. In most of them no mention is made of the finding of an artery of unusual size, but it seems to me that a careful examination would have revealed this condition in some of the hitherto unexplained cases of hæmorrhage.

Downie,<sup>1</sup> speaking of tonsillotomy, says: "Of the vessels in the immediate neighborhood, the ascending pharyngeal is the only one which might be damaged, and this only in unwarrantably free incision into the tonsils, never in excision. Billroth<sup>2</sup> removed the left tonsil of an hysterical lady. The organ was pulled toward the middle line and a fold of the pharyngeal mucous membrane was probably drawn out and cut with the tonsil. A fearful hæmorrhage occurred, which Billroth thought came from some large branch of the ascending pharyngeal."

In Schmidt's "Jahrbücher," Vol. 186, is related a case of severe hæmorrhage after cutting off the left tonsil. Various hæmostatics were tried unsuccessfully, and in three hours the common carotid was tied. In this case the cause of the hæmorrhage was thought to be some abnormal ramification of the vessels.

Other similar cases might be cited, but these will serve to show the importance of bearing in mind the possibility of having to do with a condition such as I have described, and also the need of making a thorough examination before operating on the throat.

#### A CASE OF EMBOLISM OF THE LEFT VERTEBRAL ARTERY, WITH AUTOPSY.<sup>3</sup>

BY F. W. STUART, M.D., OF BOSTON.

G. W., aged sixty-two, came to the Carney Hospital on December 31, 1885, with the following history: His grandfather, father, two brothers and one sister had died of what he called "softening of the brain," and the account given of the disease, rendered it probable that they had had general paresis. In other respects the family history was negative. The patient considered himself well until three years ago, though he had for years been very corpulent, weighing at one time two hundred and fifty pounds. In the fall of 1882, he fell and injured his knee, but attached no importance to the injury, though it obliged him to limp about for a time. Soon after he began to have trouble with his eyes and was operated on for cataract

at the Eye and Ear Infirmary, where he learned incidentally that he had fractured the patella of the left knee.

For the last three years his health had been poor, loss of strength, weight, and appetite being the most prominent symptoms, added to which for the last few months there had been attacks of severe pain in the stomach, and vomiting, which lasted for from twenty-four to forty-eight hours and always began at night, when they were also most severe. The patient was positive that the attacks began about midnight, and the ingestion of food seemed to bear no relation to them.

The vomitus was as a rule, of a black or dark brown color, and once or twice was distinctly like coffee-grounds in appearance. The patient admitted having used alcohol rather freely during his younger days, though for ten years past he had been a total abstainer.

When at the hospital he was cachectic and some chronic affection was suspected. Physical examination failed to reveal anything except a decrease in the area of liver dullness. Careful examination of the urine, chemically and microscopically, showed nothing pathological. No diagnosis being made, an expectant treatment was entered upon, under which the patient improved, and ceased visiting the hospital.

On March 10, 1886, during the service of Dr. W. N. Bullard, he reappeared, and a diagnosis of probable cirrhosis of the liver was made. This was his last visit to the hospital, and nothing further was known of his condition until May 17th, when I was called to attend him.

I then learned that during the interval between March 10th and May 13th, no evident change in the patient's condition had taken place, though he had been subject to attacks of dizziness and dyspnoea, so that he desired to have the windows opened, and these attacks had always been accompanied by profuse sweating.

He had on that day, May 13th, answered the door bell several times, but on returning the last time, he said that he had come near falling, and laid himself on the sofa. He answered several questions put to him by his wife, and nothing further was thought about his condition until an hour later, when it was noticed that he failed to recognize a friend who had entered the room. All attempts to rouse him were in vain, and finally he was put to bed, where after a few hours he became brighter, and it was not until May 17th, four days later, that I was sent for. I found the patient lying apparently comatose, though he could be aroused to answer questions, which he did slowly but intelligently. He moved all of his extremities promptly as requested, and continued to repeat the motion, as it were automatically, not even ceasing always when requested to do so. None the less there was distinct paresis. The patient recognized all visitors, and conversed with them intelligently as far as they noticed. It is certain that he recognized them sufficiently to greet them by name and properly, according to their relationship but a few minutes after they had gone he did not know of their visit, and often asked why they had not called. Difficulty in swallowing, indistinctness of articulation, and incontinence of urine completed the manifest symptoms. When asked if he wished to urinate he would pass considerable quantities of urine at a time, though repeated suggestions failed to relieve the dribbling. There was marked constipation. The patient himself complained only of weakness.

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology and Hygiene, of the Suffolk District Medical Society, February 9, 1887.

<sup>2</sup> *Eduib. Medical Journal.*

<sup>3</sup> *Lancet*, 1879, Vol. II.

I then called Dr. W. N. Bullard in consultation. The patient's condition was noted to be as above. Physical examination showed the patient to be pale and cachectic in appearance, temperature normal, pulse 80. There was a cataract in the right eye, and iridectomy had been performed on the left, so that both pupils were dilated. The left reacted to light. The reflexes were normal, and no anomaly of sensation could be detected beyond that due to mental obtuseness. Further examination revealed nothing pathological except the small liver.

Though the cause of the existing condition was recognized as distinctly cerebral, the exact nature of the lesion could not be determined upon, though a hæmorrhage was considered to be the probable cause of the trouble.

From this time, May 19th, until his death, the patient lay in bed in a semicomatose condition, replying to questions intelligently, in spite of some aphasia which appeared to be ataxic in character, but when not addressed or otherwise roused, apparently unconscious of his surroundings. There was no aphasia, properly so-called, that is, he always used the proper word when he spoke at all, although his speech was hesitating and indistinct. The paresis, which nowhere amounted to absolute paralysis, continued unabated. There were no convulsions and the patient gradually sank away, becoming constantly weaker and weaker, and died May 27th, ten days after I first saw him.

Autopsy was made May 29th, thirty-six hours after death. The body was of medium development, somewhat emaciated. The relations of the cranium to the head, and of the head to the face, were normal. The cranium alone was opened. The bone was normal in thickness, the dura, everywhere strongly adherent, could not be removed except with great difficulty. The longitudinal and transverse sinuses were empty. The pia mater was much injected, the vessels being dark and swollen. There was no fluid in the meshes of or under the pia which was neither adherent nor thickened. The brain was of normal size and consistency, its bloodvessels everywhere dilated and very prominent. They all contained numerous atheromatous patches, yellow, hard, and not contracting on section of the vessel. These patches occupied one-third to one-quarter of the whole extent of the larger arteries from the vertebral upwards. Between these hardened yellow patches the arteries were dark blue and dilated, though little or no blood was found in them.

There was no fluid in the lateral ventricles. Puncta cruenta were very few and not well-marked. The choroid plexuses were dilated and enlarged. No signs of hæmorrhage or softening were found in the substance of the cerebrum, cerebellum, pons or medulla oblongata. A grayish body the size of a pea was found at the anterior portion of the falx, there adherent. A small white thrombus was found occluding the left vertebral artery and extending into the basilar, which it partly occluded.

—An "American System of Gynecology," Messrs. Lea Brothers & Co., of Philadelphia, is announced as shortly to appear. Among the contributors are such prominent authorities as Professors Barker, Battey, Englemann, Garrigues, Goodell, Reeves Jackson, Lusk, Mundé, Reamy, Thomas, Van de Warker, and others.

## RECENT PROGRESS IN PUBLIC HYGIENE.

BY SAMUEL W. ARDOTT, M.D., SECRETARY MASSACHUSETTS STATE BOARD OF HEALTH.

### WATER-PURIFICATION.<sup>1</sup>

DR. PERCY FRANKLAND's paper upon this subject, before the British Institution of Engineers, is one of general interest, and treats of the effects of the following processes upon purification of water.

- (1) By filtration.
- (2) By agitation with solid particles.
- (3) By precipitation.
- (4) By natural agencies.

The experiments conducted had reference both to the chemical and to the biological phases of the question.

(1) *Filtration.* The following table shows the results of some of the biological experiments, with reference to the effect of filtration.

Filtering material.	Efficiency.	Organisms per cubic centimetre.		Reduction per cent.	Gals. per 100 ft. per hour.
		Unfiltered water.	Filtered water.		
Ferruginous green sand.	Initial.	80	—	100	—
	After 13 days.	8,000	1,000	88	0.73
	After 1 month.	1,280	700	79	1.14
Animal charcoal.	Initial.	Too many to count.	—	100	—
	After 12 days.	2,800	—	100	0.46
	After 1 month.	1,280	7,000	447 <sup>2</sup>	0.76
Iron sponge.	Initial.	80	—	100	—
	After 12 days.	2,800	—	100	0.40
	After 1 month.	1,280	2	99.8	0.45
Pulverised red brick-dust.	Initial.	3,000	730	76.0	—
	After 5 weeks.	6,000	400	93.0	0.48
Coke.	Initial.	3,000	—	100	—
	After 5 weeks.	6,000	90	98.5	0.50

<sup>1</sup> Approximate rate of filtration. <sup>2</sup> Increase.

The unfiltered and filtered waters were both submitted to chemical analysis, and in the case of coke and also of wood-charcoal, the chemical action of the filters was insignificant. The waters employed were urine-water and an aqueous extract of garden-soil.

The filtering stratum was made six inches in depth, and the filtering material made to pass through a sieve of forty meshes to the linear inch.

(2) *Agitation with solid particles.* In these experiments water containing micro-organisms was shaken for a definite length of time with a given quantity of finely divided matter, of similar fineness to that employed in the previous experiments on filtration. The water was allowed to subside and the clarified water submitted to examination — as soon as possible after complete subsidence had taken place — as it appeared probable that if the organisms were simply carried to the bottom by the subsiding particles, without suffering any injury, they would rapidly again become distributed through the upper layers of water by multiplication. This was amply verified by experiment.

*Spongy iron.* Water shaken with one-tenth of its weight of spongy iron for fifteen minutes. Water allowed to subside for a half-hour before examination.

<sup>1</sup> Water purification; its biological and chemical basis. By Percy F. Frankland, Ph.D., Associate of the Royal School of Mines. A paper read before the Institute of Civil Engineers, April, 1886. London.

Result:—Untreated water contained 609 organisms per cubic centimetre; after fifteen minutes agitation contained 63 organisms per cubic centimetre; reduction, 90 per cent.

*Chalk.* Urine water shaken fifteen minutes with one-fiftieth if its weight of chalk and allowed to subside five hours. Result:—Untreated water, 8,000 organisms per cubic centimetre; after agitation 270 organisms per cubic centimetre; reduction, 97 per cent.

*Animal Charcoal.* Urine water shaken fifteen minutes and with one-fiftieth its weight of animal charcoal and allowed to subside five hours. Result:—Untreated water, 8,000 organisms per centimetre; after agitation, 60 organisms per centimetre; reduction, 99 per cent.

Similar experiments with vegetable charcoal and coke showed a reduction respectively of ninety-six and one hundred per cent. after subsidence of twenty-seven and forty-eight hours.

Further experiments showed the process to be unreliable, owing apparently to numerous conditions which are necessary for its success. In some cases the number of organisms in the clear liquid was greatly increased, this being doubtless due to a re-ascension and multiplication of those which were at first carried down.

In one the following result was obtained:—Untreated water, 3,000 organisms per cubic centimetre; after agitation with coke and twenty-six hours subsidence, 20,000 organisms per cubic centimetre.

Experiments were also made with china-clay, brick-dust, plaster-of-Paris, and oxide of manganese with unsatisfactory results.

(3) *Precipitation.* The experiments conducted had reference to the process known as Clark's process, in which lime-water is the precipitant. Upon this process, Dr. Frankland remarks: "the biological efficiency of Dr. Clark's process is markedly superior to its power as a chemical purifier." With reference to care, cleanliness, and attention to details, he also says that failure will inevitably result when such processes are not under proper supervision.

(4) *Purification by natural agencies.* Referring to the effect of prolonged filtration through porous strata of soil, the writer says: Waters obtained from deep wells and deep-seated springs, often contain the merest trace of organic matter, which is only discoverable and capable of being quantitatively determined by the most refined analytical methods. Pasteur has also shown that many of these waters are entirely destitute of organic life, or in other words, are sterile.

Periodical examinations of all the London water-supplies have been made, and have revealed the fact that there is a certain uniformity in the position which the various water-companies occupy as regards freedom from micro-organisms, and also that such position has an unmistakable relation to certain factors in the mode of working, which might be anticipated from theoretical considerations. These are as follows:

(1) Storage capacity for unfiltered water.  
(2) Thickness of fine sand through which filtration is carried on.

(3) Rate of filtration.

(4) Renewal of filter-beds.

Dr. Frankland considers that such coincidence between theory and practice as is shown by the examination of the waters thus treated by filtration, proves

that the problem of biological water-purification is as tangible as the removal of the suspended particles which have for a long time occupied attention.

His final conclusions are as follows:

I. That the complete removal of micro-organisms from water, by filtration, is unattainable without frequent renewal of the best filtering materials, and duly restricting the rate of filtration.

II. That a very great reduction in the amount of organized matter in water may be accomplished by filtering materials which have hitherto been generally regarded as almost ineffectual.

III. That organized matter is to a large extent, and sometimes to a most remarkable extent, removable from water by agitation with suitable solids in a fine state of division, but that such methods of purification are unreliable.

IV. That chemical precipitation is attended with a large reduction in the number of micro-organisms present in the water in which the precipitate is made to form and allowed to subside.

V. That if subsidence, either with agitation or after precipitation, be continued too long, the organisms first carried down may again become redistributed throughout the water.

The discussion which followed the paper was critical and severe, the participants being mainly the engineers and chemists of the different water-supplies of London.

Mr. Wanklyn thought that there was one safe and rational way of regarding organic matter in drinking-water, and that was to assume that it was dangerous, and to classify waters according to the proportion of organic matter present. He attached very little importance to searching after organisms in drinking-water.

Special stress was laid upon the importance of distinguishing between harmless and pathogenic micro-organisms. Dr. Klein was quoted as stating that certain organisms were absolutely inimical to the pathogenic organisms which accompany certain diseases, the latter being unable to exist in the presence of the former, a point of great practical importance, which might account for the occasional immunity of communities supplied with grossly polluted waters.

In Dr. Frankland's closing remarks he stated that his experiments were not conducted with reference to the question of the comparative power of different processes in rendering waters wholesome, but simply to determine to what extent such processes had the power of removing micro-organisms in general. It might be safely assumed, however, that such processes could deal with any kind of micro-organisms, whether harmless or pathogenic. In the matter of filtration, there was no reason to suppose that a pathogenic organism behaved differently from a non-pathogenic organism.

Correspondence was also published from the Directors of the Berlin water-works, inclosing a summary of the investigations of the Imperial Board of Health as to the quality of the Berlin water-supply as affected by filtration through sand. This sand was of a diameter or fineness of one-half to one millimetre, the bed being sixty-two centimetres in thickness.

The two great works which supply Berlin with water are the Stralau and the Tegel, the former having eight open and three covered filter-beds with an area of 37,500 meters. From 2.88 to 3.12 cubic

metres of water are filtered daily per square metre of area. The works at Lake Tegel have an area of 20,000 square metres in ten filter-beds, to which have been added seven more. The quality of the water is tested weekly by chemical analysis, and since 1884 both chemically and biologically. The tests extended to the following particulars:

Temperature, color, freedom from odor, taste and turbidity. Contents in micro-organisms.

Chemically, as to chlorides, sulphates, nitrates, nitrites, sulphuretted hydrogen, ammonia, lime, iron, qualitatively, and quantitatively as to residue, loss in combustion, chlorine, nitric acid, ammonia and lime.

Color as seen through twenty centimetres of water, taste and smell when cold and when heated are noted.

The biological examination was conducted with the microscope and by means of pure cultivation with ten per cent. meat-juice-peptone-gelatin, one cubic centimetre of water being employed.

The diagram presented is selected from the *Arbeiten aus dem Kaiserlichen Gesundheitsamte* to illustrate the effect of sand-filtration, both chemically and biologically, upon the waters supplied to the city of Berlin.

#### PURIFICATION OF SEWAGE.

At the Thirteenth Convention of the German Association for Public Health held at Breslau, in September, 1886,<sup>2</sup> Professor Arnold, of Brunswick, presented for consideration the different methods of sewage disposal at several German cities, especially at Frankfurt, Wiesbaden, Halle, and Essen. The system conducted at Essen (and also at a few other places) is known as the Rökner-Rothe process. It is also in operation at Dortmund. The treatment is both mechanical and chemical. The chemical agents employed vary in accordance with the composition of the sewage to be dealt with, but it is claimed that their utilization is so complete that a relatively small quantity suffices at a moderate cost.

The sewage is at first admitted through a strainer to a catch-basin where the sand and coarse sludge settles, while the effluent flows through a salmon-ladder trough (misch canal) where it is exposed to the air and treated first with milk-of-lime, and then with other chemicals (the composition of which is not stated). From the trough it passes through a pipe and an apparatus shaped like an umbrella, to a tank, which, as well as the catch-basin, is shaped like an inverted cone. The precipitate of the sewage thus treated, here settles, and the sludge is pumped away, together with that which collects in the catch-basin.

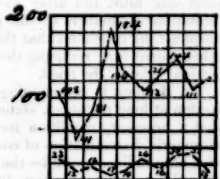

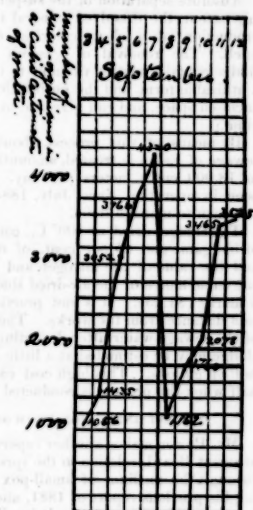

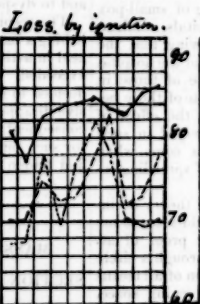

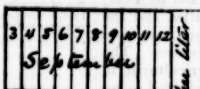

Above the tanks (which are five metres in depth), are placed inverted iron cylinders, air-tight, from seven to eight metres in height with their lower edges dipping below the surface of the sewage-level.

The upper part of the cylinders are connected with an air-pump, by the action of which the sewage (after passing through the umbrella-shaped apparatus, and then underneath its edge), rises slowly in the cylinder

#### EFFECT OF FILTRATION THROUGH SAND, STRALAN WATERWORKS, BERLIN.

<sup>2</sup> Vierteljahrsschrift für öffentliche Gesundheitspflege. B. 19. H. 1. 1887, and Centralblatt für Gesundheitspflege.

in consequence of the vacuum produced. The effluent flows away near the top of the cylinder, through an ingeniously contrived syphon, and the grease is separated by itself.

By the continuous, slow, upward movement of the sewage, treated by the chemicals, the precipitate is allowed to deposit at the bottom. The presence of this sludge acts also as a filter for the subsequent sewage, and this avoids waste of chemicals, which under ordinary methods settle to the bottom, and thus have no further action on the liquid to be treated.

Dr. Kayser, of Dortmund, sets forth the following advantages of this method of treatment:

Absolute separation of the suspended, and to a certain extent, the dissolved mineral impurities, and the production of a clean colorless effluent, free from smell. The removal of gaseous admixtures. The sludge contains matter valuable to the agriculturist in a utilizable form, and the purification is effected in an enclosed space, and can give rise to no noxious effluvia.

By means of this process, about one-fourth of the sewage of Essen is treated, amounting in wet weather to 18,000 cubic meters per day. The works have been in operation since July, 1885, and require but two men to manage them.

The sludge dried at 100° C., contains 75 per cent. of inorganic and 25 per cent. of organic substances, and the value of the nitrogen and the phosphates in one cubic metre of the air-dried sludge is estimated at 5 marks (\$1.25). It is not practicable to convey it to a distance from the works. The cost of treatment of the sewage-water after deducting the value of the sludge may be estimated at a little less than \$12 per million gallons. This high cost can be reduced one-half when the process is conducted on a large scale.

#### DISTANT INFECTION FROM SMALL-POX.\*

Mr. Power makes another report to the Local Government Board, relative to the spreading of small-pox through the medium of small-pox hospitals, confirming his previous report of 1881, and showing that the houses within the area of a half-mile from the hospital had been attacked at three times the rate of those in the next half-mile, and four times the rate of those beyond one mile, and after having tried the effect of limitation of numbers of the persons treated in such hospitals, he concludes that the time has come when other means for "reducing the chance of spreading infection" should be tried.

Dr. Bridges, in commenting upon the theory of infection at long distances, states, "it would seem to me that a necessary condition for scientific proof of atmospheric dissemination of contagion through a circle of a mile radius, would be the elimination of all means of ordinary communication in the intervening space. This would imply the necessity of choosing for observations the neighborhood of a hospital situated a mile away from inhabited houses, and where adequate care was taken to keep the inhabitants from contact with the hospital, or with other sources of contagion. Certain facts brought before the Royal Commission appeared to indicate that, where a really secluded population like that of a workhouse, or prison, was brought into very close contiguity to a small-pox hospital, no infection followed, even though no special precaution

had been taken to protect that population by revaccination. I do not think that quite sufficient weight has been attached to these facts by those who regard the theory of atmospheric contagion at long distances as proved."

#### PRESERVATION OF ANIMAL VACCINE VIRUS.

The length of time during which animal lymph proves effective, as ascertained in the experience of Dr. Cory, was as follows: This lymph was collected at a period not later than 120 hours from the time of vaccination of the animal.<sup>4</sup>

#### FOOD PRESERVATIVES.<sup>5</sup>

The French Academy of Medicine has considered the question of the propriety of employing salicylic acid for the purpose of preserving articles of food and drink. The committee appointed for the purpose reported through Dr. E. Vallin, adverse to the practice.

The first proposition under consideration was the effect upon health of moderate doses of salicylic acid continued for a period of several months or years. He concludes that such use would be especially injurious to the aged, to persons affected with renal diseases, and to dyspeptics.

The second proposition as to the propriety of establishing a maximum limit, for the presence of salicylic acid in articles of food and drink, which should not be exceeded without penalty. Such a measure was deemed to be impracticable, on account of the progressive disappearance of the acid in such articles, and the consequent difficulty of chemical analysis. Its use for such purposes is forbidden in Switzerland, Bavaria and Baden.

<sup>3</sup> Dr. J. H. Bridges's Memorandum to Local Government Board, January 10, 1887.

reasons. In the first place carefully reported cases of thrombosis of the vertebral, and still more of the basilar artery with autopsies are not common. In regard to the basilar, the more important were those of Hayem and Mayet's case.

In most reported cases of thrombosis of the basilar artery death has been rapid. In this case the symptoms were developed slowly and in a more or less distinct succession, enabling us to see their gradual progression.

At the post-mortem examination, the walls of the large and medium-sized arteries throughout at least one-third of their extent were found hardened so that they did not contract and the passage of the blood through them must have been more or less retarded both by their inelasticity and by the unevenness of the calibre in different parts of the same vessel. In some portions the lumen seemed nearly obliterated, while farther on it was in appearance increased in size. If such thrombosis as existed here should occur in a subject whose vascular channels were in a normal condition it is doubtful if a fatal result would follow. As a fact, in a person whose cerebral arteries are healthy one or both of the vertebrals may be tied without serious results, so far as the cerebral circulation is concerned. Here the occlusion of the basilar at least was only partial and with the complication of extensively degenerated (atheromatous) arteries and a weak heart death occurred from progressive cerebral anemia. The special value of a case of this character is that it directs attention to the important fact that in case of surgical operation, before undertaking the ligature of the large arteries which supply the cerebral circulation, the probable condition of the arteries of the brain should be carefully considered, and where there is reasonable ground for suspecting the existence of extensive atheroma, such operations should be considered contraindicated.

In such cases as this a complete examination of the urine should always be made. In this one there was no evidence of disease of the kidneys, so far as could be determined in this way.

DR. J. J. PUTNAM observed that in cases in which occlusion of one vertebral artery would occasion such serious effects, the collateral circulation is for some reason not easily re-established in the domain of the occluded vessel. When the vertebral is tied as a surgical measure, the ligature is applied at a point upon the vessel very much lower down than was the seat of the thrombosis in this case, and consequently does not include that portion of the trunk of the vessel from which the branches to the medulla and pons are given off. The occurrence of a thrombus at this latter higher point might easily effect the circulation in these important centres of the nervous system, and thus occasion the fatal result by progressive interference with the functions of circulation and respiration. Dr. Putnam mentioned the case of an aphasic in which there was no paralysis.

DR. BULLARD remarked that headache is one of the well-recognized symptoms of cerebral thrombosis. In those cases, in which severe headache is associated with muscular weakness there is often found a thrombosis of some cerebral vessel. In the case reported by Dr. Stuart, there was no paralysis at all, except possibly in relation to the sphincters. The right vertebral artery was found to be of the same size as the left.

DR. PUTNAM added that headache is frequently a symptom common to any severe form of cerebral disease. In two cases seen by him, in which there was persistent headache, one was in a woman who had syphilis, in which the headache was very severe, and was followed by aphasia, with complete relief to the pain in the head. The second was in a man, in which the headache had lasted for a year, and was followed by cerebral disease and sudden death.

DR. J. W. FARLOW presented a report of

#### FIVE CASES OF LARGE PULSATING ARTERY<sup>2</sup>

on the posterior wall of the pharynx. The report was accompanied by a series of illustrations showing the appearances of the pharynx, and the probable origin of the unusual vessel which occupied this strange location. Dr. Farlow stated that Dr. Otis has described the relations of the carotid artery to the tonsil, and has called attention to the possibility of dangerous hemorrhage from such an anomaly, but no one has alluded to the occurrence of alarming hemorrhage from this hitherto unrecognized cause.

DR. T. A. DEBLOIS said that he had the favorable opportunity to observe two of the patients which were contained in the list of Dr. Farlow's cases, and also saw the case observed by Dr. Morgan in Washington. Dr. DeBlois had a case in his department at the Boston City Hospital, in which after tonsillotomy, there was a most alarming hemorrhage, which continued in spite of all efforts to control it, until at the end of three and a half hours the patient fainted, when it gradually ceased, and gave no further trouble. The possibility of the anomalous distribution of the pharyngeal bloodvessels should also be borne in mind in the operation for retro-pharyngeal abscess, by which they might easily be wounded. In this case they could probably be felt by the finger in the throat, though they would probably not be visible.

DR. E. W. CUSHING stated that he once performed the operation of tonsillotomy which was followed by a terrible hemorrhage, which resisted all treatment for its control until the patient was almost exsanguine. The patient became very weak, but at last the bleeding was stayed. Dr. Cushing said that while endeavoring to control the hemorrhage, he was so unfortunate as to infect the patient's system with the germs of some septic process of which the patient died some days later, after all danger of further loss of blood had entirely disappeared. This should teach us that we should be cautious in our treatment of any condition to employ all possible precautions in the avoidance of the chances of septic poisoning.

Adjourned at 10.20 o'clock.

#### THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, March 3, 1887.

DR. WM. H. THOMPSON read a paper on

THE PATHOLOGY AND TREATMENT OF EPILEPSY, BASED ON NOTES OF SIXTY CONSECUTIVE CASES IN PRIVATE PRACTICE.

At the outset he related the case of a gentleman who was subject to sudden and transitory attacks of aphasia, always without any loss of consciousness whatever, and without the least sign of motor disturb-

ance of any kind. The phenomena of an epileptic fit were usually described as consisting, first, of an initial coma, second, loss of consciousness, third, convulsions; but, notwithstanding the prevalent opinion as to the essential clinical characters of the disease, he believed this case to be one of true epilepsy.

He then proceeded to inquire what the essential and invariable element in epilepsy really was, and expressed his conviction that it was *suddenness*. Epilepsy, he said, was the single truly sudden disease. The only affections which resembled it in this particular were laryngismus stridulus, and spasmodic asthma; but in them the suddenness of the attack was not absolute, as in epilepsy. Apoplexy, hemiplegia, and sunstroke could not strictly be compared with it, as they were in reality accidents. The attacks of hysteria and of neuralgia were not nearly so sudden as those of epilepsy. Other affections were more or less progressive in their onset. The only apparent exception was angina pectoris; but this affection was of the nature of shock. All recurring symptoms coming on suddenly, such as nausea, vesical disturbances, headache, etc., were ominous, as they might perhaps be the beginning of epilepsy. The importance of this element of suddenness could not, he thought, be overrated. *Petit mal* he considered the most real, as well as the most objectionable, form of epilepsy.

Dr. Thompson then referred to the cell discharge or explosive theory of epilepsy, and quoted Hughlings Jackson in regard to it. The exhaustion of the cells of the sensorium, he thought, was the result of the discharge which had taken place. In this connection he spoke of Nothnagel's "convulsion centre," and said that if no form of epilepsy except the *petit mal* had ever been observed, he felt certain that the explosive theory would never have been proposed. In answer to the views of Jackson and Gower he would state that in every convulsive seizure a motor discharge was granted, but to say that the first event in an attack of epilepsy was a motor discharge was quite a different matter. All motor phenomena, except the voluntary, he believed, were under the control of sensory impulse, and a sudden suspension of the regulating sensory impression might result from various causes. Any irregular motor phenomena were, therefore, due to a loss of the customary sensory influence. This explained the clinical facts of epilepsy without the necessity of supposing any additional nervous force to be called into action. It was comparable to the jar imparted to an ocean steamer when by the height of a wave the propeller was lifted out of the water; the customary resistance of the latter being temporarily withdrawn, but the power which turned the screw remaining the same.

He then referred to pleuritic epilepsy, the result of the injection into the pleural cavity of weak solutions of iodine, carbolic acid, etc. In cases of this kind the face became pale, respiration was suspended, and the pulse could scarcely be felt. Spasms, at first confined to one side of the face, afterwards became general, and finally there was epileptic coma. In a number of instances death had resulted; but no lesion of the brain was discovered at the autopsy. The effects here produced were certainly not due to the therapeutical agent employed, but were the result of a quite unusual impression upon the nerves of a cavity, wholly unaccustomed to this kind of an irritation. Of a similar character were the experiments of Brown-Sequard,

who found that in guinea-pigs and some other animals section of the spinal cord, or even of one or both sciatic nerves, was followed by well-marked epileptiform fits.

Dr. Thompson considered the phenomena of epilepsy to be due to the effect of our afferent sensory impression when there was present some abnormal condition of the cells of the nerve-centres. What this condition was, he was not prepared to say, but it seemed probable to him that it was one of malnutrition. It might be asked if he would assert that all cases of epilepsy were attended with sensory impressions in the face of the well-known fact that in certain instances there were definite lesions of the brain present. The answer was, that we do not get rid of the sensory element when we enter the cranial cavity. There is a sensory, as well as a motor, aphasia. A syphilitic gumma of the brain may be as truly an excitant of sensory irritability as an external influence; and the same is true of any source of irritation in the brain. He did not hesitate to acknowledge that a motor current could be excited by the application of an electric current after trephining the skull; but the explanation of the phenomena noted, he believed, to be in the fact of a wholly unaccustomed irritation in a centre habituated to act in response to sensory impressions. The hypothesis of a sudden impression of the ordinary sensory functions, he believed, most fully explained all the phenomena of epilepsy.

Ever since he became satisfied in his own mind that the lesion of epilepsy was to be found in the sensory, rather than the motor, centres, Dr. Thompson said he had conducted his treatment in accordance with this view; and, as a result, he had grown less skeptical than formerly of the advantages of treatment in this disease. The first thing that he arrived at was the improvement of nerve-nutrition, and by far the best agent at our command for this purpose was cod liver oil. It increased the number of blood-corpuscles more rapidly than iron, and had a greater effect upon nutrition than any other remedy. It was particularly indicated in malnutrition of the nervous system because the nerve-tissue was normally richer in blood-fat than any other tissue of the body. Hence it was to be regarded as the great prophylactic in all neurotic families. In epilepsy he never failed to prescribe it as regularly as he did in phthisis. Another advantage that it had was that it counteracted in a very successful manner the debilitating effects of the bromides. Phosphorus he had also found of much service in improving nerve-nutrition, and he usually employed it in the form of the official syrup of the hypophosphites, with the addition of one-fifth part of dilute phosphoric acid. An important part of the treatment was, in his opinion, the total exclusion of all butcher meat for a period of two years; though poultry and fish were permissible. Animal diet, he believed, predisposed to convulsions in direct proportion to the quantity in which it was used. The tendency to convulsions in the carnivora, and the absence of this in herbivorous animals, were due in his opinion to the respective diet of each class. Another thing to be avoided was eating fast, as the too rapid mastication and swallowing of food seemed to act directly on the convulsive centre of the medulla oblongata. It was possible that the habit of eating too fast might thus induce confirmed epilepsy.

Like the great mass of physicians, he had come to

place great reliance on the use of the bromides, which so successfully control peripheric irritation. If any one doubted this, let him give thirty grains of bromide of potassium to a patient with intolerant fauces in whose case he wished to make a laryngeal examination. In the long-continued use of the remedy the great thing was to control the effects of bromism.

Dr. Thompson had found that in forty per cent. of the cases observed by him, there was persistent cortical irritation, as indicated by muscular twitching during sleep, and in this class of cases he was in the habit of employing the bichloride of mercury, and sometimes oleate of mercury by inunction. This mercurial treatment he had found a very useful adjuvant to the bromides.

He used belladonna or zinc oxide in all cases in which the attacks showed any connection with disturbances in the alimentary canal. When there was reflex irritability he employed chloral hydrate or Hoffmann's anodyne in addition to the bromides. Digitalis was used in all cases characterized by vascular disturbance, or when there was involuntary discharge of urine during the epileptic attack. The published experience of Dr. Newington, who found that hot mustard baths were very useful in acute mania by cutting short the attack and inducing sleep, had led him to employ a red pepper paste at night, (one drachm of capsicum being used to the pint of hot water for this purpose), in a certain proportion of cases. In one instance, at his college clinic, a patient who ordinarily had two epileptic attacks a day did not have a single one for some weeks after this measure was resorted to; the disease being completely arrested by the peripheral excitation thus secured. These points showed, he thought, the direction in which efforts should be made by which better results might be expected in the future, and thus relieve the treatment of the grievous burden of empiricism which it had borne so long.

Dr. PUTZEL said that from a clinical point of view he did not think that Dr. Thompson's assertion that the attack was always sudden could be maintained. It was a well-established fact that there was a certain proportion of cases in which there were prodromata often lasting two or three days, or longer, such as digestive or mental disturbances. In regard to Hughlings Jackson's views, it was simply claimed by him that there was an explosive discharge of nerve-cells in epilepsy, but he did not imply that this discharge was from the motor cells especially. In fact, Dr. Putzel could not see how, in view of his well-known opinions upon this disease, he could confine the phenomena to the motor cells, since he claimed that such conditions as hemiparesis, for instance, belonged to epilepsy. Furthermore, he held that an aura which may be purely mental, may at times constitute the whole attack.

Dr. Putzel thought that in *petit mal* paralytic symptoms were extremely rare. Paralytic trouble, in his opinion, was usually met with after prolonged convulsions, and occurred as the result of the exhaustion incident thereto. Besides, he could not understand how the sensory impulse inhibits the motor, as stated by Dr. Thompson. In regard to so-called pleuritic epilepsy, it was not proved that the convulsions in the cases referred to were epileptic. They were, no doubt, epileptiform, but unless a convulsive habit was established, they could not, in his opinion, be said to

belong to true epilepsy. In the same way, he did not think that the convulsions of children in teething, the attack being merely the result of a temporary local irritation, could be called epilepsy, although they were often epileptiform in character. Belladonna he had used principally in nocturnal epilepsy, in conjunction with the bromides. He agreed with Dr. Thompson that epilepsy was a disease of impaired nutrition, and that cod liver oil was often, therefore, of very great benefit in the treatment.

Dr. WM. H. DRAPER said that as regards the pathology of epilepsy, the author of the paper did not seem to have thrown much light upon that obscure subject. He had confounded with the disease certain convulsive affections which he did not think could be regarded at all as epileptic. As Dr. Putzel had remarked, he had spoken of convulsions produced by a variety of peripheral irritations as if they were true epilepsy, and in this opinion he could not agree. In infants and others we often met with conditions in which convulsions were so easily induced, and which so readily disappeared under treatment adapted to remove the source of irritation and improve the nutrition, that he did not think that these temporary conditions could properly be compared with that grave affection which we call epilepsy.

In regard to the management, he said that he agreed with Dr. Thompson as to the treatment of the impaired nutrition which was so common with cod liver oil and tonics. In addition to improving the general nutrition it was necessary to study very carefully the peripheral irritation which produced the attack; and in a large number of cases he had found that this was to be looked for in the gastro-intestinal tract. He could not say that he agreed with Dr. Thompson as to the danger of animal food in epilepsy. On the contrary, he was inclined to think that the origination of an attack was much more likely to follow the too free ingestion of starchy food and sweets. He preferred, therefore, that his patients should use principally animal food and milk, and take a diminished quantity of the carbo-hydrates; and very good results had followed the adoption of this plan of diet.

The next most important thing was the administration of some drug having the effect of diminishing the extreme excitability of the nervous centres which was always the essential precursor of an attack of epilepsy. For this purpose, nothing was equal to the bromides. These were all the elements of a rational treatment of this disease, and yet he presumed that it was the experience of every physician present that there were certain cases in which all the measures referred to were of little real value. Bromide of potassium sometimes signally failed unless pushed to the point of producing the most profound bromism; so that the patient preferred to have fits at regular intervals rather than endure the wretched hebetude which the drug induced.

Dr. E. DARWIN HUDSON, JR., said that in epilepsy the attack was characterized by a withdrawal of mental control and unconsciousness, and that he had never met with but one case of convulsions in which consciousness was retained. He believed that in this disease there was cerebral anemia and an explosion due to disturbance of the vascular equilibrium. From a clinical standpoint it was often difficult to say what constituted epileptiform attacks and what true epilepsy. Successive seizures produced by peripheral irritation

not infrequently seemed to eventually result in epilepsy if they were allowed to go on without interference. He agreed with the other speakers that the bromides constituted the most reliable means of treatment.

DR. THOMPSON said that he did not mean to imply that epileptic attacks have no prodromata. On the contrary, it was extremely common in his experience to meet with patients who were almost always aware of the imminence of an attack. But a prodroma was not the attack itself, and it was this that he particularly referred to when speaking of the suddenness of the affection. He had studied this matter with especial care, and his conclusion was that epilepsy is to be distinguished from all other diseases by its suddenness. In regard to Hughlings Jackson's views, he said that he never understood his statements as applying only to motor discharges; but it certainly was a fact that he particularly dwelt upon the explosion of motor cells. Instead of regarding sensory impulses as being of a stimulating character, Dr. Thompson said he was inclined to look upon these as a regulating force. Hence the study of the connection between any motor disturbance and the antecedent sensory impression, seemed to him of importance as indicating the direction in which advances in our knowledge of epilepsy were to be looked for.

In regard to confounding all sorts of convulsions with epilepsy, he remarked that Dr. Putzel and others who had spoken did not regard the convulsions of dentition as of an epileptic character; but he had compared these attacks very carefully with those of acknowledged epilepsy, and he had been entirely unable to discover any difference whatever between the two. First births, and especially when the children were males, he went on to say, gave a larger percentage of cases of epilepsy than subsequent ones, on account of the greater compression of the brain to which the infants were subjected during the process of labor. He then related a case of his own in which on account of contracted pelvis, there was great delay in the delivering of the child, and after it was born, he had been obliged to use oxygen gas for three hours in order to resuscitate it. When it was nine months old the child began to have convulsions, and these continued from time to time until its death, at the age of seven years. He studied the attacks in this case with great care, to see if there was any difference between them and the ordinary convulsions of children from dentition, and he became convinced that a more mythical distinction could not exist.

DR. DRAPER replied that in saying that convulsions were epileptiform he implied mainly that they had the form of epilepsy, but not the substance. He thought there was a great difference between these temporary seizures and the regular occurrence of seizures in true epilepsy. In the form of attack he was quite willing to acknowledge there was no perceptible difference.

DR. A. D. ROCKWELL read a paper on

#### THE VALUE OF ELECTRICITY IN THE TREATMENT OF EPILEPSY.

There were a certain proportion of cases of epilepsy which failed to receive permanent benefit from the use of the bromides, as usually employed, but which apparently completely recovered after the assistance of electricity had been invoked, in connection with the bromides; epilepsy was in this respect analogous to

chorea. Arsenic was universally acknowledged to be a remedy of the greatest value in this affection; but there are certain cases in which it failed to afford relief unless its use was supplemented by electricity. Dr. Meredith Clymer, in some excellent remarks on the treatment of epilepsy, stated that he had never heard of a permanent cure of the disease under the use of the bromides, either alone or in combination. While this might be regarded as an extreme statement, the suggestion that the best results will follow only if we call to our aid every measure that will tend to increase and develop vital power would generally, command itself to all.

It was not alone, therefore, on the theory of a special influence on the nerve centres, or over the cerebral circulation, that he employed electricity as an adjuvant to the bromides, but also because of its undoubted and powerful constitutional effects. It was a tonic, but it had both stimulating and sedative effects. In 1878 Dr. Rockwell said he had read a preliminary paper on the treatment of epilepsy by electricity, but it was since that date that he had obtained the best results with this agent. In this, as in various other forms of central disease, he almost always associated and alternated central galvanization with general faradization.

Central galvanization was analogous in its effects to the bromides; producing a profound tendency to drowsiness. In some cases sound sleep had been induced with the subject in an upright position, while receiving the current through the brain. He recalled one patient under treatment by central galvanization who was repeatedly put to sleep within a minute after the beginning of the application. In epilepsy there was a disturbance of the centres of the cerebro-spinal system. There was an hyper-excitability of the nerve-cells, which was dynamic rather than physical; and this hyper-excitability was kept in check by galvanism as readily as by the bromides.

The total number of cases in which he had employed electricity was twenty-eight, but ten of the patients had abandoned the treatment too early to allow any conclusions to be drawn from them. In three cases the electricity seemed in no way to assist the action of the bromides. In eight cases the use of electricity was attended with a certain amount of benefit, varying in different instances, but not to such a marked degree as in the remaining seven cases. In two of these the patients recovered entirely, and in the other five there was very decided improvement.

Among the conclusions arrived at by Dr. Rockwell are the following:

Electricity possesses a certain value in the treatment of epilepsy.

It is not claimed that it can alone cure the disease, but in many instances it is of great service as an adjuvant to the bromides.

In the nocturnal variety its good effects are especially marked.

The methods of application should be central galvanization and general faradization.

It is important that the agent should be administered with great care. Anything like a shock should be avoided, and the applications should not be continued too long at a time.

The treatment should be kept up, with suitable intermissions, for two years after the last occurrence of epileptic symptoms.

THE CAUSE OF CONTRACTURES IN LATERAL SCLEROSIS OF THE SPINAL CORD.

THE symptoms by which primary, amyotrophic, lateral sclerosis are principally known have been well described by Charcot in his masterly treatise, and consist in a progressive paresis, first in the superior, then in the inferior members, with slowly-developing atrophy of the affected muscles, complicated, in the second stage of the disease, by contracture of those muscles. The attitude of the arm, forearm, and hands is very striking. The arm is applied to the body, and the muscles of the shoulder resist when any attempt is made to separate this member from the trunk. The forearm is semi-flexed and in pronation, and it is impossible to bend it without pain; the hand is rigidly flexed on the wrist, and the fingers curved into the palm of the hand. Subsequently, the same kind of spasmodic rigidity affects the lower extremities.

Vulpian, who has been conspicuously successful in wrestling with the great problems of nervous physiology, has endeavored, in a work just published,<sup>1</sup> to furnish an explanation of the pathogeny of this contracture. It is a symptom which appears almost invariably when the lateral tracts in their posterior parts are the seat of sclerosis, whether this be primary or secondary (descending degeneration from encephalic lesions). It is also very commonly witnessed in multiple sclerosis, and in primary sclerosis of the posterior columns, complicated with sclerosis of the contiguous portions of the lateral columns.

In answer to the question: "Is it the destruction of these parts of the lateral columns which determines the muscular spasms, the contracture, or is it the irritation of these parts?" Vulpian replies: "It is not their destruction." In numerous instances, he has practised in animals ablation of these columns, in their entirety, upon a limited portion of the cord. The animal (a chloralized dog) has come out of the anesthesia of the operation paralyzed in the posterior extremities, which were completely flaccid, and, till the time of its death, there was never any contracture.

<sup>1</sup> Vulpian. "Maladies de la Moelle," t. II, Paris, 1887.

Generalizing from these experiments, Vulpian concludes that simple loss of function of these pyramids in man will not cause contracture, but that this symptom must be due to the irritation, of which the lateral columns are the seat in cases of sclerosis of these regions of the cord.

Some striking experiments have given support to this view. In dogs profoundly chloralized, he has exposed the spinal cord in the dorso-lumbar region to the extent of two to three centimeters, and carefully cauterized the lateral tracts with a crayon of nitrate of silver, or a knitting-needle heated in the flame of a spirit-lamp. When the experiment was well made (that is, when the cauterization was limited to one lateral column), he always observed contracture of the posterior limb of the corresponding side. It is true that this contracture did not generally last but two or three days, but this could be explained in this way: Experimental irritations have not the persistence of morbid irritations; if they are of feeble intensity, they are soon extinguished; if they are of great intensity, they rapidly determine a destruction of tissue, which prevents their effects from lasting. In Vulpian's experiments, the spasmodic rigidity was always followed by paralysis, more or less complete. The appearance of this paralysis at the moment when the lateral column which has been cauterized begins to undergo softening proves, Vulpian adds, that the contracture is not due to the cessation of action of the part cauterized, but to the process of irritation there set up. An argument leading to the same interpretation is furnished by the fact that the contracture does not appear as soon as the animal begins to come out of the chloral sleep, as would be the case if the spasm had for its cause the abolition of the functions of the lateral column. It is only at the end of two or three hours after the return of the animal to complete consciousness that the contracture manifests itself.

These considerations lead to the conclusion that the contractures are due to the irritation, of which the lateral columns are the seat.

Are these spasmodic phenomena the direct results of irritation of the motor fibres of the lateral conducting tracts of the cord? If that were so, sclerosis of these motor conduits should be constantly complicated with a state of spasmodic contraction of the muscles of the members which receive their nerves from the altered regions of the cord. Unfortunately for this view, many cases of symmetrical lateral sclerosis have been observed and published, in which there was little or no contracture of the muscles of the members, or of the trunk. Even in cases where the superior extremities were contracted in a marked degree, the inferior members have often been found free from spasm, and yet the autopsy has proved that the pyramidal regions of the lateral columns were altered below the points of origin of the nerves of the lower extremities. These facts seem to militate against the view that the contractures are due simply to irritation of the motor fibres in the lateral conducting tracts.

These considerations have compelled Vulpian to regard the irritation which causes the contractures in symmetrical lateral sclerosis as of a reflex kind. It has been shown that the posterior region of the lateral columns contains excito-motor nerve-fibres, connected with both horns of gray matter, and this part of the lateral columns seldom escapes participation in the morbid process in primary sclerosis of those columns. Even the pyramidal tracts of the lateral columns contain a small number, though variable, of excito-motor fibres. Moreover, the posterior horns of gray matter, on which borders the portion of the lateral columns which undergoes alteration in symmetrical lateral sclerosis, is rich, both in sensory and excito-motor elements. Of these three groups of excito-motor and sensory elements, which has the principal rôle in the production of contracture? There is every reason to believe, says Vulpian, that the irritation starts in certain of the sensory or excito-motor elements of the posterior cornua. If the contracture were due to irritation of the excito-motor fibres of the lateral columns, it should be a constant phenomena in sclerosis of those tracts, which cannot be affirmed. If it were due to irritation of the postero-cortical layer of the lateral columns, it should often be witnessed in sclerosis of the posterior columns, while, in fact, contracture is of exceptional occurrence in this disease.

The explanation of the contracture, then, is this: "In cases where the irritation of the lateral columns propagates itself to the excito-motor or sensory elements of the posterior horns, the persistent excitation of these elements provokes the continuous activity of certain groups of cells of the anterior horns, and thus gives rise to tonic contractions of the muscles which are supplied by nerves taking their origin in those cells."

"This physiological interpretation seems to harmonize with the results of the examination of the medullary reflex function in patients affected with lateral sclerosis, and in whom contractures tend to manifest themselves, or already exist. The reflex function in these cases is always exalted, as is shown by the exaggeration of the reflex movements provoked by the percussion of the tendons (the tendo-Achillis, the patella-tendon, etc.), and it is further exemplified by the reflex trepidation of the foot when flexed on the leg, and by the spasmodic tremblings which manifest themselves, under slight provocations, in different parts of the body."

#### A MASSACHUSETTS LAW FOR REGISTRATION IN DENTISTRY.

OUR readers have already been informed that the Committee on Public Health of the Massachusetts Legislature reported a bill providing for the establishment of a Board for Registration in Dentistry — a measure similar, in many respects, to the one which was passed a year or two ago with regard to practitioners of pharmacy.

The Dentistry Bill was carried successfully through the House, but, on reaching the Senate, for some reason, presumably because it was not understood by the members, it was defeated without much discussion, on its passage to a third reading, by a vote of 13 to 8, which vote gave rise to the statement in our last issue. That this action was taken somewhat in the dark was shown by the fact that a motion to reconsider received unanimous sanction the following day, when, after a moderate discussion, the bill was passed. According to the provisions of the bill, a Board of five examiners is to be appointed by the Governor and Council, to consist of dentists of good repute, who are not connected pecuniarily with any dental college. This Board is to register the name of every person engaged in the practice of dentistry within the Commonwealth, such practitioners to make oath to the fact before a notary public, and then to be allowed to practise under the license of the Board. All other persons desiring to practice dentistry are to be examined either orally, or by written test by the Board, and, if found qualified, to be certified as legally authorized to practice. The original proposition, to admit to practice all graduates of dental schools, on presentation of their diplomas, is thus seen to have been modified in the direction of a healthy stringency, by requiring actual knowledge, in the place of reputed knowledge.

All persons practising dentistry otherwise than according to the preceding regulations are punishable by fine or imprisonment, except that practising physicians, graduates from the medical department of any incorporated college, are exempt from the provisions of the act.

A somewhat similar bill was passed by the Legislature in 1882, but was found to conflict with the charter of the Massachusetts Medical Society, in abridging the privileges of practice conferred on its members; and, after that defect had been corrected, the bill was vetoed by Governor Long, it is said because it required applicants for registration to be graduates of some college, and, therefore, was held to savor of intolerance and exclusiveness.

The chief defects of the present bill, which we nevertheless regard as, on the whole, a desirable and proper one, are, first, that the protection of the public is interfered with by the inclusion within the pale of registration of all existing practitioners, in whom any amount of incompetence and ignorance is covered up by the fact of their being actually engaged in dental practice at the time the bill becomes law; so that it will be a generation before the existing incompetent dentists are eliminated from the profession, and the public is protected from their blunders.

Again, the expression, "engaged in the practice of dentistry," is capable of great latitude of interpretation; many a young lawyer and doctor are said to be in practice when they have simply put out a sign, and have never had a case. What is to hinder a man from making claim, on the same ground, to being in dental prac-

tice. Or, indeed, since the interval between special acts of practice may be quite indefinite, how can any one who has ever pulled a tooth be refused registration if he apply for it? When registration was begun in England, the term, "*bona fide practice*," was used, but even this was found to be too vague to serve as a satisfactory criterion.

We have heard the opinion expressed by men prominent in this speciality, that they would gladly see a registration bill which should apply to dentistry as a branch of general medicine, but that it was illogical to apply a supervision to the special branch, which was denied to the wider and more important whole to which the part belonged. Indeed, this argument was the strongest one that was urged against the measure in the debate in the Legislature, although it is true that the bill implies a distinct recognition of the relation of dentistry to general medicine in the provision that graduates in medicine are, *ex facto*, authorized to practice the speciality.

Whether the now accomplished registration laws for pharmacy and dentistry shall pave the way to a general medical registration, is a question that time alone can solve. But when the public comes to recognize the fact that the medical profession has no interest in such a measure comparable with the interest of the public itself in its own protection, it may arrive at the conclusion that it is as important to have a guarantee of the competence of the surgeon who operates on any other organ, as of him who operates on the teeth; and that it is a very partial protection to life to scrutinize the dispenser of drugs, while no guarantee whatever is required that the person who directs what shall be dispensed knows anything about the nature of the drugs he prescribes, or the diseases he assumes to treat.

When our legislators, having fortified the public against these minor dangers, shall address themselves to the more imminent one, they will find the members of the medical profession, like other good citizens, ready to approve their action; but there is no reason to believe that the great body of self-respecting physicians will ever take the initiative in a step where their motives are so liable to misinterpretation by the ignorant and the vicious.

#### THE BENEFITS OF A MEDICAL EDUCATION.

THE season of commencements is near at hand, in fact, has begun in some of the medical schools, and the diploma mills are under full blast. Soon the newly constituted doctors and doctresses of medicine, with the long-coveted and sometimes hard earned parchment, will press into the serried ranks of the profession.

We are not of the number of those who have nought but discouraging words for students of both sexes who, at the numerous medical schools throughout this great country are grappling with the difficul-

ties of medical study. With large numbers, the choice of this, in preference to every other learned profession, was a deliberate one — it was the expression of a conviction that the physician's is the most noble, liberal and beneficent calling. We do not, moreover, lose sight of the fact that many enter our medical colleges for the discipline and for the knowledge obtained through a thorough study of medicine in its collateral as well as in its essential branches. This discipline and this knowledge are of the utmost practical value. The fact is now recognized that a medical education is both a scientific and a liberal education. Without something more than a superficial knowledge of those primary branches which underlie what is known as the study of medicine, we do not believe that anybody at the present day, can be said to be liberally educated.

There is then a point of view from which we would say that the greater the number who (with ability to master it), enter on the study of medicine, the better. We would fain see society educated up to the plane of the average physician. It would not be the millennium, but it would be a great progress.

But it is another thing when medicine is studied as a means of earning a livelihood, and not cultivated, like virtue, for its own sake. It has been again and again said that ours is a crowded profession, and there are nowhere any good "openings." The newly equipped graduate who would win his bread and butter from the "practice of physic," must to a large extent obtain patronage to the detriment of his fellow laborers in the profession.

It is still the struggle for existence, in which the law of survival of the fittest has a general applicability. Many must be content with comparative poverty, while others will seem to their grudging conferees always to have more than their share. But these inequalities are inevitable to the human lot, and not even the advantages of superior attainments will always secure to the eager aspirant the "lion's share," if his competitor has more brazen assurance, and a more winning way with the public.

But the country is vast, population is ever on the increase, and multitudes of physicians are needed; the ranks of the profession are constantly being thinned by death and by other causes, and every medical student has a right to feel that somewhere there will be room for him where he will be welcome.

And, at any rate, he should rest assured that the culture and training which he is acquiring is its own reward. He may be compelled to ask his support of a community which encourages quackery more than it encourages science, and is more impressed by a fine equipage and all that, than by brains and talent, a community that fosters superstitions like hot-house plants; but he who has gone deeply into the science, discipline, and lore of medicine, will feel that he has found the only corrective and antidote to much of the nonsense that is rife; he will have the satisfaction of knowing that he has attained to a higher level, and this is no mean satisfaction.

## GAS AND KEROSENE STOVES FOR HEATING APARTMENTS.

WE publish in another column a letter from a careful observer in regard to the heating of apartments by gas and kerosene stoves, which is a matter of no little importance.

Gas and kerosene stoves are used to a considerable extent for cooking and also for the heating of small apartments. For the former purpose they are mainly used in summer, in sea-shore cottages and private residences and at a time when windows are open and free ventilation is secured; for the latter purpose they are used in cold weather, most commonly in small rooms with little or no ventilation.

One gas stove consumes more oxygen than a dozen men. These stoves are made both with and without stove-pipes for connection with a chimney, and they can be used in rooms having no connection with a chimney. Their effect upon the air is bad enough in either case, and in the latter positively dangerous.

A certain firm in one of our cities, advertising such stoves, states as one of their advantages, that they can be used either with or without the stove-pipe connection. To us, the possibility of using such stoves without the stove-pipe connection, should be reason enough for condemning them.

## MEDICAL NOTES.

— Professor Swiefl, of Erlangen, has received a call to Leipsic, and Dr. Mikulicz, of Cracow, to Koenigsberg, in Prussia.

— The late ceremonies in celebration of the nineteenth birthday of Kaiser Wilhelm have not failed to redound to the glory of his physicians, to whom the public is ready to ascribe much of the credit of the patient's advanced age and robustness. The Court Journal gives a picturesque account of the physician always on duty in the room of the Emperor. The latter suffers from a weak heart, the inaction of which causes his frequent falls. This physician, we are told, while the Kaiser sleeps, keeps his fingers on the pulse, and when he perceives any indication of greater weakness, wakes the Emperor and administers strong stimulants. The picture should offer suggestions to the cartoonist.

— A newspaper dramatic critic remarking upon the expressions to be heard among a dispersing audience, after a performance of *Frou Frou* by Mme. Bernhardt; "How realistic her death scene!" and struck by the fact that probably scarcely any of the audience knew what they were talking about, asked an old physician whom he met in the lobby what he thought of it. The latter replied: "Well, it was effective. Is n't that quite sufficient? I never saw anybody die that way; but I presume Mme. Bernhardt may have. I don't believe, however, that our great actors and actresses study models of expiring people in the hospitals, as they are said to in popular legends. No two persons

die alike any more than they live alike, and if Mme. Bernhardt were to endeavor to be realistic rather than artistic, my impression is that the spectators would say that she did not know how to die correctly."

BOSTON.

— The Faculty of Harvard College has promulgated the extraordinary rule that in all cases in which the college has heretofore required a physician's certificate to the fact of illness of absent students, such certificates must specify the *cause* of illness in order that the faculty may be able to judge of the validity of the excuse for absence! The faculty may not be aware that a similar attempt to require information as to the cause of illness of government employes at Washington, was, as we informed our readers last January, resisted by one of the most prominent practitioners of that city and that his refusal to comply was supported by the head of the department, Secretary Bayard. The faculty makes the double mistake of requiring the physician to betray his professional confidences and of assuming a power of supervision over a medical opinion as to the severity of the disease, or the requirements for its treatment.

— On the arrival of the Steamship *Kansas*, from Liverpool, at East Boston, last week, two stowaways were found, who with less wisdom than is usually shown by their kind, had hidden themselves in the lower hold whence the hatches prevented them from escaping, as they hoped to do the first day out. They took no food on board with them, and consequently got nothing whatever to eat during the thirteen days of the ship's passage, except a little water which trickled down the inside of the iron ship. They made vain attempts to kill the rats which they could hear about them, but which in the utter darkness they failed to do. The lads, who were eighteen or nineteen years old, were in a state of extreme inanition when discovered, but with care rallied again.

— A complimentary banquet was given to Mr. Theodore Metcalf at the Revere House, Tuesday evening, March 29th, by the Boston Druggists' Association in commemoration of his completion of a half-century of an active business career as a Boston Druggist. Speeches were made by Dr. Oliver Wendell Holmes, William Warren, Mayor O'Brien and others.

NEW YORK.

— The coffee-booths erected by the ladies of St. Luke's Church, of Brooklyn, which have been doing a very good work during the past winter, have now been closed for the season. The receipts, which were \$65.77 less than the expenses, amounted to \$1,467.50, and there were 104,033 meals served at a cost of one cent each.

— There is said to have been quite a large amount of illness during the winter among those occupying quarters in the Capitol building at Albany, from the Governor down; and it certainly seems strange that the Legislature, which is generally supposed to look pretty sharply after its own interests, has not long

since taken efficient measures to secure a satisfactory sanitary condition of the premises. It will, perhaps, be remembered that a year ago, on account of the numerous complaints that reached them, the State Board of Health directed its consulting engineer, Prof. James T. Gardner, to make a thorough investigation of the buildings, and that he afterwards prepared a very elaborate report setting forth the existing defects and the measures which he thought necessary to remedy them. But, notwithstanding the fact that this was published in the form of a very readable pamphlet, showing how even Senators and Assemblymen do not escape the bad effects of sewage-contaminated air and poor ventilation, the Legislature has never taken any action in regard to the matter.

### Miscellany.

#### THE MEDICAL NEWS ON THE HOLYOKE SMALL-POX CASES.

THE *Medical News*, March 19, 1887, says, in its editorial columns: "Dr. Abbott, of the Massachusetts Board of Health, reports the results of his investigation into the origin of recent cases of small-pox among the workers at the paper-mills at Holyoke. He traces the cases to imported linen rags that had passed through the New York Custom House, and were marked 'disinfected.' This fact may be expected to arouse attention to the present system of treating foreign rags, and to reopen the discussion of their fumigation at the seaports, which, last year, gave the Treasury Department so much trouble."

We fear some one has been trifling with the *Medical News*, the only correct statement in the above being the one that Dr. Abbott "reported the results of his investigation;" and "this fact" not being a fact at all, we need not expect attention to be aroused, etc. The Patent Disinfecting Company dies very hard. An accurate statement of the results of the investigation of the Holyoke small-pox cases may be found on page 243 of this JOURNAL, March 10th, to which may be added the statement: The two girls who were attacked worked in a room directly over the duster in which both domestic and foreign rags were dusted.

#### THE MEDICO-LEGAL ASPECTS OF SKIN-GRAFTING.

A SUIT has lately been before the courts of Atlanta, Ga., in which, however, it may have been based on private and personal grounds, rested ostensibly on the claim for damages done by a physician in taking from a boy, with the latter's consent, pieces of skin from the arm for grafting. The facts as given by the *Atlanta Medical and Surgical Journal*, are as follows:

"On August 30, 1886, in the presence of Drs. Hardon, Westmoreland and Howell, Dr. Henry Wile, of this city, proposed to a boy of thirteen years to submit to the removal of some small skin-grafts from his arm to be placed upon an extensive ulcerated surface on the head of his cousin, a little girl somewhat younger, whom he had accompanied to the office.

The boy readily consented, and minute grafts were excised without causing him any inconvenience.

"In the afternoon of the same day, the father of the boy went to the office and charged Dr. Wile with having cut 'his son's arm to pieces.' He subsequently swore out a warrant charging him with assault and battery; whereupon Dr. Wile waived examination and gave bond in the sum of two hundred dollars for his appearance at the City Court.

"The trial was before Judge Van Epps, without a jury, and after reviewing the facts as above given, the Judge stated that the boy had more than ordinary intelligence and discretion, and that a child of his age, under such circumstances of intellectual development, could commit crime and be punished according to law. He considered, therefore, that he had a right to give his consent, so that no crime was committed, and the case was dismissed."

#### ON THE TREATMENT OF NERVOUS HEADACHE.

"AFTER a number of trials," says Professor Arnold,<sup>1</sup> of Baltimore, "with various remedies which stand in repute for the relief of nervous headache, I give now the preference in the neurasthenic variety to a combination of ether and tincture of cannabis indica, in doses of twenty drops of the former and ten of the latter. Sometimes these remedies act better after a good night's rest has been obtained from a full dose of chloral."

#### THE PEABODY IMPROVED DWELLINGS TRUST OF LONDON.

THE compatriots of the distinguished philanthropist whose good works live after him in so many different quarters of the globe, cannot fail to be interested in the effort which he made to secure more sanitary dwellings for the poor of London. The twenty-second annual report of the trustees of the Peabody Donation Fund, as reviewed by the *Lancet* is satisfactory, whether viewed from a financial, social, or sanitary point of view. The half million of money given and bequeathed by Mr. Peabody between the years 1862 and 1873 has by the accumulation of rent and interest very nearly doubled itself, for on December 31st last it amounted to £910,668. That the object of the donor has been faithfully carried out is evident from the fact that by the end of last year the trustees had "provided for the artisan and laboring poor of London" 11,150 rooms, without counting bath-rooms, laundries, and washhouses, and that these rooms were occupied by a population of 20,228 persons; this shows an increase of 12,431 upon the number in residence at the end of 1876, ten years before. The various buildings contained 5,014 separate tenements, including 74 of 4 rooms, 1,782 of three rooms, 2,350 of two rooms, and 808 of single rooms; the average rent of each tenement being rather more than 4s. 9d., and of each room rather less than 2s. 2d. It is stated that the average weekly earnings of the head of each family in residence at the close of the year was rather less than 23s. 10d. The report contains the usual figures bearing upon the vital statistics for last year of the population of more than twenty thousand persons inhabiting those buildings. The birth-rate was

<sup>1</sup> Medical and Surgical Reporter, February 28, 1887.

equal to 42.4 per 1,000, exceeding by 10 the mean rate for the whole of London. This high birth-rate is evidence of the abnormal age constitution of the population, which contains an exceptionally large proportion of young adults, and consequently of children, and necessarily a very small proportion of elderly persons. The death-rate among this population including, as is stated in the report, the deaths of those residents who were removed to hospitals, was equal to 19.3 per 1,000, which is 0.6 below the mean rate for the whole of London. Bearing in mind that this population belongs exclusively to the working classes, and further that its exceptionally large proportion of young children more than counterbalances the effect of its small proportion of elderly persons, this death-rate may be taken to afford evidence of the sanitary condition of the residential population of these buildings. It is especially satisfactory to learn that in this working class population housed in improved dwellings, the rate of infant mortality in 1886 did not record 149 per 1000 registered births against 958, the mean rate in the whole of London.

#### INDICATIONS FOR THE USE OF NITRO-GLYCERINE.

DR. TRUSSEWITSCH, in an instructive paper on the use of nitro-glycerine published in the *St. Petersburger Medicinische Wochenschrift*, and reproduced in summary in the *Lancet*, February 19th, points out that the value of this drug in various affections—angina pectoris, migraine, and neuralgia (which he describes as angioneuroses), as also in sea-sickness, some forms of anemia, faintness, palpitation, and other diseases—depends upon the existence of an irregular distribution of blood, which condition may be inferred from a certain degree of pallor of the skin, especially of the face, often coexistent with a weak pulse and a small rigid radial artery, which frequently is situated at some depth. When on the other hand, headache and neuralgia occur in patients with chronic congestion of the subcutaneous veins of the face, nitro-glycerine is to be avoided; and similarly it is of no use in asthma, when the face is reddened in consequence of emphysema. If, however, a pale face exists with angina pectoris, migraine, giddiness, shock, toothache, or sea-sickness, the best results may be looked for by giving nitro-glycerine. The regulating effect of the drug exercises an influence over the congestion of internal organs similar to that brought about by bloodletting; and in these congestions, whether of lung, brain, or kidney, when they are of a temporary character, the pulse is generally found to be slow and of low tension—a fact which, as the author remarks, is sufficiently well known in reference to the fever-free periods of acute hyperemia of the lung and kidney. Dr. Trussewitsch lays down as a rule that the condition of the pulse is the best indication for the employment of nitro-glycerine, and the most trustworthy guide as to the dose with which to commence the treatment. The smaller the radial artery is, the more rapidly it dilates under the action of the drug, and the less the secondary effects produced; on the other hand, the fuller the pulse with a distended radial artery, the less it is affected; and finally, the softer the artery, with a weak pulse, the greater the secondary, and the less the general effects. Single-drop doses of the 1

per cent. solution are sufficient in cases of small pulse, but with a full pulse it will be found that the full effects cannot be produced with less than two drop doses. When there is a soft artery with a weak pulse, subnormal doses only should be given—a quarter to half a drop. After the trial dose is given, the patient's sensations of pulsation and pain in the head, as well as the distension of the radial artery under the finger of the physician, will be the guides for increasing the dose. The author finds that the best modes of administering nitro-glycerine are the simple dropping of the solution on the tongue, and by means of tablets; much less satisfactory results were obtained when given mixed with water.

#### Correspondence.

##### FLOATING KIDNEY.

HARVARD MEDICAL SCHOOL, March 27, 1887.

MR. EDITOR,—At the close of his exceedingly interesting paper in your last number, on what proved to be a floating kidney, Dr. F. C. Shattuck asks, when did his patient's kidney first become movable. He points out that it could not have acquired a mesentery (more properly a meso-nephron) suddenly, and that the symptoms were first noticed when the young man was only eighteen.

It seems to me that there is a radical defect in the classification of floating kidneys, which should be divided into those with a meso-nephron, presumably congenital; and into those without one, presumably acquired. The presence of a meso-nephron is decidedly rare. The usual story is that through a strain, tight lacing, or the absorption of the fat around the kidney, that organ becomes loose and slides about behind the peritoneum without acquiring a meso-nephron. I presume it is possible, especially if the kidney is enlarged by a morbid growth, that one should be formed. It is a pity that in the report of the autopsy there is no mention of the origin of the renal artery, for if it came from some unusual source, this, in conjunction with the presence of the meso-nephron and the youth of the patient, would make it almost certain that the abnormality was congenital.

I find in my notes a brief account of a case which I saw in the dissecting room at Bowdoin College in 1873. The left kidney lay in the pelvis. The main artery came from the left common iliac, another came apparently from one of the mesenteric vessels, but as the specimen had suffered at the hands of the students before I saw it, I did not succeed in tracing it. There was a regular meso-nephron, but I was told that when found the kidney was not movable. I suppose there were peritoneal adhesions that fixed it. In this case the peculiarity was undoubtedly congenital. It is interesting as showing, if the statement made to me was correct, that a floating kidney may become a fixed one. Possibly the adhesions may have occurred very early. Very truly yours,

THOMAS DWIGHT, M.D.

#### A PROPOSITION TO TRANSLATE AND PUBLISH THE MEDICINE AND HYGIENE OF THE TALMUD.

DAYTON, OHIO, 110 East 2d Street, March, 1887.

TO THE MEDICAL PROFESSION,—Ever since the publication of my address on "Jewish Hygiene and Diet, the Talmud, and various other Jewish Writings, heretofore Untranslated," delivered before the American Medical Association in 1884, at Washington, D. C., I have constantly been urged by the profession to translate and publish the Medical and Hygienical portion of this "wonderful" com-

pilation, the Talmud. I therefore beg to state to the profession at large, that I have concluded to translate and publish from the Talmud everything relating to medicine, provided, that prior to the undertaking I can receive one thousand subscribers for the book, and such subscription may be addressed to me in the following words:

I, the undersigned, agree to take one (or more) copy of the Talmudic Medicine of Dr. von Klein, which shall not exceed \$5.00 in cost for five hundred octavo pages, or at \$1.00 per each hundred pages, payable at delivery.

Under no other circumstances will I ever undertake this labor, which must be traced from hundreds of thousands of copies, and which has heretofore not been accomplished by any living man. No more copies will be printed than the number subscribed for, and fifty extra copies for distribution to the principal medical journals for review.

CARL H. VON KLEIN.

#### APARTMENT-HEATING BY GAS AND KEROSENE STOVES.

SAVANNAH, March 17, 1887.

MR. EDITOR.—Gas stoves, and kerosene stoves, when used to cook light meals, are to some extent a nuisance—more especially to one's neighbors—but may readily be tolerated. When used to furnish a permanent supply of heat, they can rarely be sanctioned. I should like to mention a little experience of my own, in Savannah, where this method of heating offices is becoming popular.

Occupying, for a part of the day, a small room, containing 1,100 cubic feet of air, I introduced a small kerosene stove for warmth. The heat yielded was sufficient to raise

the temperature of the room about eighteen degrees, which served my purpose sufficiently well. I had to stand some odor; but otherwise, I did not experience any personal discomfort from the peculiar atmosphere. One evening, however, I saw that the reading-lamp was dim; the flame had shrunk to one-half of its usual size; thinking that the housekeeper had neglected it, I carried it into the entry, but was surprised to find it burning brightly. Placed in the room, it again burnt low; opening the window relieved the difficulty. The same thing occurred on another evening, when, having with me Wolpert's air-testing apparatus,<sup>1</sup> I found that the amount of carbonic acid in the air had reached sixty-seven parts per ten thousand, the normal amount being three or four parts.

This numerical statement is only a fair approximation to the truth; but may be regarded as near enough to be of practical importance. It is not at all surprising that such an effect is produced by a pair of burners, each four inches long, generating as much CO<sub>2</sub> as eight or ten common lamps. In a well-built house with tight doors the effect might be doubled.

I have in mind the case of an elderly Boston school-teacher, whose health has been gradually declining under the combined influence of school-room air, protracted colds, and a kerosene stove in her sitting-room. The products of combustion besides CO<sub>2</sub>, may or may not have an injurious effect, but the enormous waste of oxygen, by itself, must have its effect on health.

It may be that the public need some warning upon this point, which your JOURNAL is in a position to give.

Respectfully yours, D. F. LINCOLN, M.D.

<sup>1</sup> Described by Dr. S. W. Abbott in the Medical and Surgical Journal, August 17, 1886.

Deaths reported 2,027: under five years of age 738; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 225, acute lung diseases 333, consumption 320, diphtheria and croup 106, measles 53, diarrhoeal diseases 31, typhoid fever 24, scarlet fever 22, cerebro-spinal meningitis 14, malarial fevers 14, whooping-cough 11, erysipelas seven, puerperal fever six, small-pox two. From typhoid fever, Baltimore four, Pittsburgh and New York three each, Boston, Portland and Lowell two each, Brooklyn, New Haven, Charleston, Fall River, Lynn, Lawrence, Springfield, New Bedford and Brockton one each. From cerebro-spinal meningitis, New Haven four, Boston, Baltimore, Pittsburgh, Milwaukee, Worcester, Lowell, Fall River, Springfield, Somerville and Holyoke one each. From scarlet fever, New York 13, Boston, Baltimore and Providence two each, Brooklyn, District of Columbia and Lowell one each. From malarial fever, New York 10, Baltimore two, Brooklyn and New Orleans one each. From whooping-cough, New York five, Brooklyn two, Boston, Baltimore, District of Columbia and Milwaukee one each. From erysipelas, New York four, Brooklyn two, Providence one. From puerperal fever, Brooklyn, Boston, District of Columbia, Pittsburgh, Providence and New Bedford

one each. From small pox, New York and Brooklyn one each.

In the 23 cities and greater towns of Massachusetts, with a population of 1,086,673 (population of the State 1,941,462) the total death-rate for the week was 22.68 against 20.27 and 18.55 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,245,000, for the week ending March 5th, the death-rate was 31.3. Deaths reported 3,776: infants under one year of age 805; acute diseases of the respiratory organs (London) 459; measles 152, whooping-cough 93, scarlet fever 41, diarrhoeal diseases 34, diphtheria 31, fever 31, small-pox (Manchester) three.

The death-rates ranged from 11.6 in Bolton to 31.2 in Manchester; Birmingham 22.6; Bradford 22.3; Halifax 19.8; Hull 21.7; Leeds 21.3; Leicester 19.0; Liverpool 23.5; London 20.2; Newcastle-on-Tyne 24.9; Nottingham 17.5; Sheffield 19.8; Sunderland 15.3.

In Edinburgh 22.2; Glasgow 25.7; Dublin 28.1.

The meteorological record for the week ending March 19, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.		Relative Humidity.				Direction of Wind.		Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.
	Daily Mean.	Daily Mean.	Maximum.	Minimum.	7.00 A. M.	3.00 P. M.	11.00 P. M.	Daily Mean.	7.00 A. M.	3.00 P. M.	11.00 P. M.	7.00 A. M.	3.00 P. M.	11.00 P. M.	Duration of Rain.	Amount in Inches.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 19, 1887, TO MARCH 25, 1887.

GRAY, WM. W., captain and assistant surgeon. Leave of absence further extended two months. S. O. 62, A. G. O., March 17, 1887.

EDIE, GUY L., first lieutenant and assistant surgeon. Leave of absence extended three months. S. O. 67, A. G. O., March 23, 1887.

FOINDETER, JEFFERSON D., first lieutenant and assistant surgeon, (recently appointed). Ordered for temporary duty at United States Military Academy, West Point, N. Y., relieving Captain Richard W. Johnson, assistant surgeon, who will return to his proper station (Fort Adams, R. I.) S. O. 62, A. G. O., March 17, 1887.

REYNOLDS, FRANK, captain and assistant surgeon (retired). Died March 3, 1887, at Oakland, Cal.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING MARCH 26, 1887.

CORDERO, F. J. B., assistant surgeon. Detached from the Navy Yard, Boston, and placed on waiting orders.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING MARCH 26, 1887.

BAILLACHE, B. H., surgeon. To proceed to Mobile, Ala., Pensacola, Fla., Ship Island, Miss., and New Orleans, La., as inspector, March 14, 1887.

LONG, W. H., surgeon. Granted leave of absence for seven days, March 16, 1887.

GOLDSBOROUGH, C. B., surgeon. Granted leave of absence for thirty days, March 14, 1887.

DEVAN, S. C., passed assistant surgeon. To proceed to Tacoma, W. T., as inspector, March 19, 1887.

LONG, W. H., Surgeon. Leave of absence extended five days, March 23, 1887.

URQUHART, F. M., passed assistant surgeon. Relieved from duty at Norfolk, Va., ordered to Washington, D. C., special duty, March 22, 1887.

PETTUS, W. J., assistant surgeon. When relieved by passed assistant surgeon Gutiérrez to remain Charleston, S. C., waiting orders, March 24, 1887.

#### SOCIETY NOTICES.

SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION.—There will be a meeting of this Section at 19 Boylston Place, on Wednesday evening, April 6th, at 8 o'clock. Dr. J. Leslie Foley will read a paper on the "Morbid Changes and Surgery of the Nails." Dr. H. L. Burrell will give a *résumé* of "Four Months Experience in Minor Surgery at the Boston City Hospital." G. H. MONKS, M.D., Secretary.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—The annual meeting of the Boston Society for Medical Observation will be held at the Medical Library, 19 Boylston Place, on Monday evening, April 4, 1887, at 8 o'clock. Readers: Dr. M. H. Richardson, "A Series of Abdominal Cases." Dr. T. F. Sherman, "Pleurisy with Effusion." At 9 o'clock, election of new members; election of officers for the ensuing year.

CHARLES P. STROB, M.D., Secretary.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT.—THE SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE will meet at 19 Boylston Place, on Wednesday, April 13th, at 7.45 o'clock. Papers: Dr. Henry Jackson, "A Case of Acute Infectious Universal Myositis." Dr. R. H. Fitz will open the discussion. Dr. F. C. Shattuck, "Four Hospital Cases. (1) Tetany; (2) Hemophilia; (3) Cirrhosis of the Liver; (4) Peritonitis, with Perforation of the Abdominal Wall." Dr. F. Minot will open the discussion. Dr. C. F. Folsom, "Two Cases, Multiple Neuritis (idiopathic), Multiple Neuritis (alcoholic)." Drs. S. G. Webster and J. J. Putnam will open the discussion.

F. I. KNIGHT, M.D., Chairman.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—THE ANNUAL Meeting of this Association will open in New York on the second Wednesday in August (the tenth).

## Nature.

### ON THE PHYSIOLOGY OF EXERCISE.<sup>1</sup>

BY EDWARD MURSEY HARTWELL, PH.D., M.D.,  
Associate in Physical Training, in the Johns Hopkins University, Baltimore.

ENOUGH has been said, I think, to show that muscular exercise exerts a potent and important influence upon the growth of the body, and upon the elaboration and perfecting of its more familiar systems of organs; but, thus far, its most important effect, that upon the nerves and brain, has been only alluded to. The nervous element involved in muscular exercise is oftener overlooked than recognized by the mass of writers on the subject. Maclaren, whose book on "Training in Theory and Practice" is the best of its class in English, defines exercise as "muscular movement" simply, and declares its object to be "the destruction and renovation of tissue." This is the ordinary view, from which you will find but little deviation in the vast majority of the text-books on physiology, and of the books and articles on exercise, whether they have been written for school-girls or medical students.

I would not have you take this for my individual doctrine, though the statement expresses the result of my inquiry and reading. "We seek in vain in most physiological text-books," says Du Bois-Reymond, "for instruction respecting exercise; if it is given, only the so-called bodily exercises are generally considered, and they are represented as merely exercises of the muscular system. Therefore, it is not strange that laymen in medicine, teachers of gymnastics, and school-teachers believe that. Yet it is easy to show the error of this view, and demonstrate that such bodily exercises as gymnastics, fencing, swimming, riding, dancing, and skating, are much more exercises of the central nervous system, of the brain and spinal marrow. It is true that their movements involve a certain degree of muscular power; but we can conceive of a man with muscles like those of the Farnesian Hercules, who would yet be incompetent to stand or walk, to say nothing of his executing more complicated movements."

The arm of the blacksmith has been so often brought into play by writers and talkers on exercise, that every school-boy credits the statement that muscles grow larger, harder, and stronger when duly exercised, and become weak, flabby, and wasted if they are suffered or forced to remain inactive. It is less obvious, though it can hardly be doubted, that use and disuse work similar effects in the case of nerve cells and fibres, both sensory and motor. There is abundant evidence, though much of it is of the negative sort, to show that exercise of the muscles not only reacts upon the nerves and centres with which they are connected, in such wise as to enhance the power and ease with which they originate and transmit stimuli, but that it also leads to an increase in the size, number, and elaboration of their parts. But this evidence is chiefly to be sought in the writings of those who have made the normal and diseased conditions of the nervous system their special field of study, since text-book makers and the writers of popular articles seldom make use of the material which has been accumulated by professional physiologists, and those who devote themselves to the

study and care of the idiotic, the paralyzed, and the insane.

The fact must never be lost sight of, that a single muscle is not a simple organ, but is made up of two clearly-distinguishable, though conjoined mechanisms: a contractile, executive mechanism, the muscle proper; and a stimulating, regulative mechanism, consisting of nerve-fibres and gray-matter nerve cells. Each mechanism has its bloodvessels for supplying food and drainage; and the amount of blood supplied to each is proportionate to its functional activity. If, in life, the two mechanisms become dissociated, or if either suffer from mal-nutrition, unregulated exercise, or structural depravity, the dual organ is thrown out of gear, and its working becomes disordered or abolished, in much the same way as when it is attempted to split a human being into a mental part and a bodily part, and to train the dis severed fractions to functionate as entities. Muscular movement is, then, a resultant effect, due to the balanced working of the conjoined mechanisms alluded to. The nervous mechanism is concerned in a somewhat higher kind of work than that of its muscular colleague, and may be said to represent the movements of which the latter is the seat and instrument. Between the nervous arrangement which represents the twitch of a single subcutaneous muscle inserted into the base of a hair-follicle, and that which represents and governs the varied and rapid muscular adjustments which characterize the hand and fingers of a cunning craftsman or artist, there exists every grade of complication.

If we compare an adult man and one of the highest of the lower animals, in respect to the movements of which they are capable, we find that they possess many in common, but that man is distinguished from the brute by certain movements, such as those involved in maintaining the erect posture, and in the action of the hands and vocal organs; and that, corresponding to these two classes of movements, there are two classes of nervous mechanisms, by means of which they are represented. These mechanisms have been well termed fundamental and accessory, respectively.

Similarly, it is demonstrable that, while the human infant and adult possess many nervous mechanisms identically alike in structure and function, the adult is characterized by certain other mechanisms, whose structural peculiarities, connections, and powers have been evolved and superadded, as the result of growth and training. The law of evolution, as applied to the nervous system, is now very generally recognized by neurologists. In Ross's "Diseases of the Nervous System," this law, which was originally enunciated by Herbert Spencer, is described as "a progressive integration, both of structure and function, during which there is a passage from the uniform to the multifiform, the simple to the complex, from the general to the special. The nervous system of man is, at first, similar to that possessed by all animals which possess a nervous system, or, at any rate, all those which are sufficiently elevated to possess a spinal cord; but, as development proceeds, the nervous system of man becomes gradually differentiated from that of an ever increasing number of the lower animals, while still maintaining a general likeness to the nervous system of the higher animals up to the time of birth. This, then, constitutes the fundamental portion of the nervous system of man; but after birth, the accessory portion, which, up till this time, only appears in a

<sup>1</sup> Concluded from page 302.

rudimentary condition, now undergoes progressive development. It will thus be seen that the fundamental portion is first developed, and that the super-addition of the accessory portion greatly increases the multifariousness, the complexity, and the speciality of the human nervous system, and that it is the latest product of its evolution."

As might be expected, the structural elements of the nervous system follow this law. The many-branched nerve cells, having a process prolonged to form the axis-cylinder of a nerve fibre, are the most highly organized and special of nerve cells, but they begin as small, round, uniform, unbranched cells. The medullated nerve fibre made up of axis-cylinder, sheath of white substance, and the outer investing membrane, is the highest form of nerve fibre. At the other end of the series stands the primitive nerve fibril, a bundle of which may be said to constitute an axis-cylinder. Among intermediate forms are axis-cylinders with no sheath whatever, axis-cylinders covered only by a sheath of white substance, and non-medullated fibres, consisting only of an axis-cylinder enclosed in a fine, thin, structureless sheath. At birth the fundamental portion of the nervous system of a human infant is characterized by the presence of branched cells and medullated fibres in contra-distinction from the rudimentary accessory portion which contains small round cells, primitive fibrils, and non-medullated fibres. Later, if all goes well, the round cells become branched, and the non-medullated fibres become medullated.

There are certain areas in the gray matter of the fore-brain of man whence proceed, it is now generally held, stimuli to the most important groups of voluntary muscles. In one of these regions are the centres which control the different groups of muscles of the upper extremity, and for the sake of simplicity we may consider that the centres of the muscles, which move the shoulder, elbow, wrist, and fingers lie near to and are connected with one another. The movements of the shoulder and elbow are fundamental and well-organized in the infant, as compared with those of the wrist and fingers which are accessory and later acquired. In order that the movements of the different segments of the fore-limb should be properly co-ordinated as to force, direction and degree, their motor centres must habitually discharge their stimuli in due sequence and degree. This comes only through practice. Experiments on young puppies show that their motor areas are not sufficiently developed until they are ten days old, for them to make voluntary movements with their limbs. Ferrier declares that "the degree of development and control which a puppy reaches in ten days or a fortnight, is not attained by the human infant under a year or more." The infant, through the growth and development of the appropriate accessory centres, first gains control over its foot and leg, then over its arm and hand, and later over tongue and lips. It is evident that the arms of a blacksmith, and those of a five-year-old boy, and of an infant, differ greatly as regards size, strength, and skill; but the differences which exist between them, reside in the nervous mechanisms which represent the movements of which their respective muscles are capable, rather than in the muscles themselves. Not only are the motor nerves of the blacksmith the largest, but the cells in his motor areas are also more numerous, larger, more branched and more widely connected with other cells. Exercise plays, if not

the predominant, at least a very considerable part in producing this result. The effects of exercise are at once seen, if one compares the right and left arms of the average blacksmith with one another. It is well-known that the centres which control the right hand are situated in the cortex or outer layer of gray matter of certain portions of the left fore-brain: and that those which control the left hand are in the right fore-brain. Flechsig, who has made exhaustive studies as to the course and number of the motor fibres which connect the muscles of the two extremities with their respective main centres, concludes that the number of fibres going to the right hand, is to the number of fibres going to the left hand, as three to two.

The mere disuse of a muscle causes it to diminish in size. This wasting is technically termed atrophy. The most extreme forms of muscular atrophy and paralysis, are due to diseased conditions which originate in nerve centres or nerve fibres, though to the uninstructed eye the muscles would appear to be the only organs affected. Lesions in the central nervous system may cause the bones to atrophy, as well as the muscles. The development of a group of muscles of an entire limb, or of one side of the body, may be arrested by reason of certain forms of central nervous disease which occur in infancy and childhood. Observations made upon the brains of persons born with an arm or hand lacking, taken in connection with observations made on the brains of those who have had a hand or arm amputated, go to prove that the suppression or considerable diminution of certain movements brings about a condition of atrophy or arrested development, as the case may be, in those centres which would normally represent such movements. One may attain to the stature and semblance of manhood, and yet, through the arrested development of certain of his motor centres, be nothing better than an infant or a mere animal, as regards his powers of action: while paralysis and atrophy may reduce a young age by stage, to the condition of an untrained child, or of a helpless idiot, or even to that of a living corpse.

The functional improvement of the nervous mechanism, which represents any movement, whether it be simple or complicated, automatic or voluntary, is the most important effect of muscular exercise. It is not altogether clear just how it comes about that through trial and repetition, an action which is at first a difficult feat, becomes a pleasurable accomplishment, then a routine performance, and at last an almost instinctive act. But there is a settled conviction, among those who know most about healthy and diseased nerves, that the frequent or habitual passage of stimuli from a given group of cells through definite fibres to the muscles, concerned in a given movement, leads to some kind of rearrangement of the molecules composing the irritable protoplasm of fibres and cells, so that less and less resistance is offered to the passage of subsequent impulses from the same source. Somehow or other the memory of past actions and the stimuli which evoked them becomes imbedded or organized in the motor centres. The principles of physical training, whatever its aim and end may be, are based upon the power of the nervous system to receive impressions and register them or their effects; or in other words, upon its ability to memorize the part it plays in acquired movements, and on occasion to recall and revive such movements. His once too vividly impressed sensory centres cause the burnt child to dread flame:

and the difficulty of interesting an old dog in new tricks, except so far as he delights to criticise and decry them, arises from the preoccupation of his centres by old impressions rather than from their increasing insusceptibility to fresh ones.

From careful studies made as to the character of the dreams of the blind, it appears that the memory of visual objects is not organized until between the fifth and seventh year of life. Persons born blind do not dream of objects in the outer world, and those who become blind, before attaining their fifth year, do not dream of objects seen by them before their loss of sight. They are blind-minded as well as blind-eyed as regards such objects. There are authentic cases recorded of persons whose memory of objects, seen before the access of their blindness, persisted for twenty, thirty, and even fifty years. Then the record of their visual impressions became effaced and they ceased to dream of objects in the outer world. The case of a man born without either hands or feet, is in point here. Although he had eyesight, he did not dream of executing hand or foot movements; yet he had sufficient use of his stumps to write what is termed a good hand. There was no record of hand or foot movements in the centres which ordinarily control such movements; so that he was unable to dream of movements which he had never executed. On the other hand, the instances are very numerous in which men, who, having lost a limb by amputation, could feel their fingers or toes while awake, and dream in sleep or when awake, of making complicated movements with their lost members. "Persons who have had an arm amputated," says Dr. Weir Mitchell, "are frequently able to will a movement of the hand, and apparently to execute it to a greater or less extent. A small number have entire and painless freedom as regards all parts of the hand." They must be blind-minded, indeed, who can deny in the face of such facts, that muscular exercise plays an important part in the development of brain power.

It is so difficult to find a true and succinct statement of the effects and value of exercise in its relation to the nervous system, that I cannot forbear quoting freely from a most admirable article by an eminent English authority, on insanity and kindred diseases, Dr. J. Crichton-Brown.

"The view hitherto taken of exercise in relation to education," he says, "has been far too narrow. The idea has been, and as far as it went, it was a correct idea, that exercise is useful in education, because it sustains and improves bodily health by expanding the lungs, quickening the circulation, shaking the viscera, and promoting growth in the muscles and bones. But we now know that besides doing all these things, exercise may be made to contribute to brain growth, and to the symmetrical development of the mental faculties. In all muscular movements there is action and reaction. When a movement is willed, a current is sent forth from the brain and the muscle contracts. But that is not all; the instant that the muscle contracts the sensory nerves take up the tale, and accurate reports are conveyed to the brain of all that is going on at the scene of action. Nerves distributed to the muscle itself, to the skin covering it, to the joint which it moves, carry back to the supreme centre precise information as to the effects of its mandate, and the information thus received is carefully registered for future guidance. For just as there is a memory of

sensory impressions, of the sights we have seen and the sounds we have heard, so is there a memory of motor acts, of the movements we have performed, and of the mode in which we accomplished them. Thus the muscles not only, by the locomotion which they render possible, enormously widen the field from which our sense-impressions are gathered, but also by the experiences which their own activities involve, expand our mental resources a thousand-fold. An analysis of our ideas at once reveals to us that we have few that are of purely sensory origin; our ideas of form are not mere revived optical impressions, which are properly limited to color, but ocular impressions combined with ideal ocular movements. Our idea of a circle is a combination of an ideal circular outline with an ideal circular sweep of the eyeballs, or it may be of the tactile impressions coinciding with an ideal circumduction of the arm or hand, or perhaps both these factors, combined. And so it is with our ideas of weight, distance, and resistance, which all involve sensory and motor factors, and to revive in memory any such ideas is to revive both the sensory and motor elements of their composition, and to repeat definitely in certain nerve centres the processes which correspond with certain motor acts.

"Now the centres of motor ideation require to be exercised in order that they may be properly developed, and may contribute usefully to mental processes; and hence muscular training is likely to assume a more important and precise place in our educational systems of the future than it has hitherto done.

"These facts, that cerebral centres never properly exercised do not develop, and that, when once developed, they are not so liable to waste on the withdrawal of their appropriate stimuli, or when they are cut off from their natural activities, strongly inculcate the importance of educating every centre at its nascent period, and the danger of postponing education till the nascent period is over. A large district of the brain is made up of motor centres, and is concerned in motor ideas. The growth of that district is evidently to some extent dependent on muscular exercise, and if that is withheld, at the growth-period, the development of that district is arrested. It is not only so, but that district is made up of a series of centres in relation with different groups of muscles, and each centre is dependent for its development upon the activity of its own group of muscles; and the defective exercise of any group of muscles during the growth-period of its own particular centre (the growth-periods in most of the motor centres having different starting points) will result in the dwarfing of that centre, and a corresponding hiatus or a general weakness must exist in the whole mental fabric.

"From this, we might deduce that swaddling bands so applied at birth as to restrain all muscular movements, and kept on during infancy and childhood, would result in idiocy—a speculation to which the wretched muscular development of most idiots and imbeciles, and the fact that their mental training is most successfully begun and carried on through muscular lessons, give some countenance. We should also have to infer that, in order to build up a sound and vigorous brain, we must insure free exercise to the different groups of muscles in the order of the development of their centres, and must in no degree interfere with the natural sequence of their evolution. That being so, we must necessarily ascertain what that

natural sequence is which is so important a guide to education, for, in our present ignorance of it, we may unwittingly be doing much mischief.

"Suppose that we are encroaching on the time at which hand-centres ought to receive their most valuable education — their nascent period — and are devoting that time to the cultivation of the tongue and lip centres, then we should be impairing the full development of the brain; for the hand-controlling centre, if not fully exercised at its nascent period, can never afterwards attain to the highest cunning. But it seems that not only tongue, but hand, and foot, and eye, and arm, and every muscle of the body, must be trained in due season, if education is to do what we expect of it, and result, not in headaches, and imbecilities, and nervousness, and insanity, but in well-balanced growth of body and mind.

"The differences which we notice between man and man in deportment, gait, and expression are but the outward and visible signs of individual variations in the development of the motor centres of the brain; and the stammerings, grimaces, twittings, and antics, which are so common and annoying alike to those who suffer and those who witness them, are probably, in many instances, the effects of neglected education of some of those centres, and might have been abolished by timely drill and discipline."

It must be evident, I think, that muscular exercise deserves more attention than is usually given it, and that, when properly chosen, regulated, and guided, it not only does a man good, but makes him better; at least, it may make him a better man, in many respects, than his father was, and enable him to transmit to his progeny a veritable aptitude for better thoughts and actions. Herein lies the power of the race for self-improvement, and the evolution of a higher type of man upon the earth.

"The body of the accomplished man becomes," says Bagehot in his "Physics and Politics," "by training, different from what it once was, and different from that of the rude man; it is charged with stored virtue and acquired faculty, which come away from it unceasingly. . . . The special laws of inheritance are, indeed, yet unknown. All which is clear is that there is a tendency, a probability, greater or less, according to circumstances, but always considerable, that the descendants of cultivated parents will have, by born nervous organization, a greater aptitude for cultivation than the descendants of such as are not cultivated, and that this tendency augments, in some enhanced ratio, for many generations.

"I do not think any who do not acquire this notion of a transmitted nerve-element will ever understand the connective tissue of civilization. We have here the continuous force which binds age to age, which enables each to begin with some improvement on the last, if the last did itself improve, which makes each civilization, not a set of detached dots, but a line of color, surely enhancing shade by shade. There is, by this doctrine, a physical cause of improvement from generation to generation, and no imagination which has apprehended it can forget it; but unless you appreciate that cause in its subtle materialism; unless you see it, as it were, playing upon the nerves of men, and, age after age, making nicer music from finer chords, you cannot comprehend the principle of inheritance, either in its mystery or its power.

"These principles are quite independent of any

theory as to the nature of matter or the nature of mind. They are as true upon the theory that mind acts on matter, although separate and altogether different from it, as upon the theory of Bishop Berkeley, that there is no matter, but only mind; or upon the contrary theory, that there is no mind, but only matter; or upon the yet subtler theory, now often held, that both mind and matter are different modifications of some one *tertium quid*, some hidden thing or force. All these theories admit, indeed they are but various theories to account for the fact, that what we call matter has consequences in what we call mind, and that what we call mind produces results in what we call matter; and the doctrines I quote assume only that. Our mind, in some strange way, acts on our nerves, and our nerves store up the consequences. Somehow the result, as a rule, and commonly enough, goes down to our descendants. These primitive facts all theories admit, and all of them labor to explain."

#### A FEW FRAGMENTARY REMARKS ON THE RADICAL RELIEF OF INFLESHED TOE-NAIL.<sup>1</sup>

BY R. E. COTTING, M.D.,  
Consulting Surgeon to the Boston City Hospital.

In January last I operated for radical relief of infleshed toe-nail, in the presence of several members of this Society.

The patient was a young woman, on whom I had performed the same operation on the other great toe, four years before. At that time, a brother, older than herself, received the same treatment for a like ailment. Indeed, some sixteen years ago, I performed four operations simultaneously (on the two sides of the two great toes) for the mother of these patients, making, in all, seven similar operations in the same family.

In each of these seven cases the result was successful in the fullest sense of the term. The ailment was completely eradicated, never to return. The nails were not injured in the process. They afterwards grew naturally, without pain or hindrance of any kind, soon acquiring normal usefulness. The toes, as usual after the peculiar method employed, were greatly improved in shape and general appearance. Walking also became easy and agreeable, in any kind of boot or shoe.

The method resorted to in all these cases was one devised by myself, more than forty years ago; and, although frequently followed by myself and others here and elsewhere, has never, to my knowledge, failed to effect a radical cure.<sup>2</sup>

<sup>1</sup> Read before the Roxbury Society for Medical Improvement, March 24, 1887.

<sup>2</sup> Singularly enough, as I was going to this meeting, with my report fully prepared, a friend showed me the New York Medical Journal for March 19, 1887, wherein Dr. R. F. Wier, of New York Hospital, in a report of four months' hospital work, three hundred and ninety-nine operations, including one for "ingrowing toe-nail," at page 319, says: "This operation of Cotting's (sic) often fails, and I have learned from my clinical assistant, Dr. Bartley, how to do it better than I did." From which it appears, not that Cotting's operation fails, but that Dr. Wier failed to do the operation. Of course, it should be properly performed, and by one who comprehends the scheme of it. How his "one case" resulted he does not say; presumably, however, from the contrast, in success. He calls it a "very small operation." Compared with his capital operations it may be, but it may be one of great importance, also, to a disabled patient wishing for the power of locomotion, and freedom from torturing pains. Moreover, there are scores of these patients to one requiring amputation at the hip-joint. On the other hand, Dr. Gay, of the

It is a very simple procedure: Etherize the patient, unless he object. Remove with the knife the diseased fleshy parts, together with a large and thick slice of the healthy and adjoining side of the toe, Figure 1, *a c*. Let the cut begin or go well back, as at *d e*, Figure 2,<sup>2</sup> and let it be guided by the edge of the nail, which should be exposed, but need not, nor its matrix,

be involved or injured thereby. Dress the wound with lint or absorbent cotton, firmly compressed upon it by a narrow roller-baudage, and cover the whole with a good-sized piece of oiled muslin or silk, neatly secured, in order to prevent any extra oozing of blood.<sup>3</sup>

This is the whole of it. The patient lies abed for a few days, or immediately sits up, or hobbles about, as he pleases, even going to his work at once, if necessary. From the moment of the operation there remains only a clean-cut wound, to heal as other wounds of like dimensions, with less pain or annoyance in it than previously in the disease; while such as there is, rapidly decreasing, soon departs altogether.

This operation, one of the simplest ever devised for this affection, differs from all the others in its fundamental principle and purpose, namely, the producing of a radical cure by *ciatricial contraction*, and that by means of a wound of sufficiently large extent, in healthy as well as diseased parts. For, as such a wound heals, the remnants of the lateral fleshy nail-furrow, if any remain, together with the soft parts adjoining, are drawn in by the contraction, and, in this manner, are kept away from the edge of the nail. Thus the nail thence after, in its ordinary growth, has nothing to imbed itself in, or even to impinge upon. A return of the affection is thus put entirely out of the question.

Such was the method pursued in the case now reported. Those present and assisting can bear witness to its simplicity and ease in performance, as well as to the complete success and radical cure, then shown to them, of the previous operation on the same patient.

Though a minor operation in surgery, one may deem himself fortunate if able to suggest an easy and radical remedy for an often-met affection so exquisitely painful and disabling as this frequently becomes, or so intractable as it has heretofore proved to be. To this end unnumbered attempts have been made, without satisfactory results. Beaudes states<sup>4</sup> that Velpeau counted up nearly a hundred such. "This large number," he says, "attests the importance of this little malady, and the difficulty of its cure." Velpeau himself always adhered to the evulsion of the nail, which procedure he greatly ameliorated.

Some, perhaps, may be still reluctant to give up the Boston City Hospital, who probably has performed this operation many more times than any other practitioner, in the "New Reference Handbook of Medical Sciences," Wood & Co., New York, 1887, Vol. IV, page 36, says: "Having performed this operation many times during the past eighteen years, I have never yet seen a case in which the result was not permanent and satisfactory."

<sup>2</sup>The wood-cuts have been kindly lent by their owner. See Boston Medical and Surgical Journal, May 8, 1879, page 261, where they illustrate a very good article on the subject of this paper.

<sup>3</sup>Finally the bleeding is readily controlled, during the operation and dressing, by an assistant holding the toe, and compressing the lateral arteries between his thumb and index finger. But in the case now reported, Dr. Garceau (in a procedure original with himself) skilfully wound the toe with small rubber tubing, Esomarch fashion, and thus rendered the operation absolutely bloodless till the dressings could be applied.

<sup>4</sup>Dictionnaire de Médecine, Vol. II, p. 552.

old ways, "barbarous methods" Dr. Gross called them, but evidences that our procedure meets with ever-increasing approval are continuously coming in; and, if it be the *good thing* we contend that it is, this may be a sufficient apology for often urging its general adoption, and for again bringing the subject before this Society.

### THREE CASES OF LABOR, TWO BEING BREECH AND THE OTHER ARM-PRESENTATION, WHERE THE LEGS WERE EXTENDED, AND THE FEET WERE NEAR THE FACE.<sup>1</sup>

BY DR. J. S. GREENE, OF DORCHESTER.

The cases which I am to report illustrate an infrequent form of dystocia, and one "little considered in our text-books."

**CASE I.** Mrs. A. B., a young, strongly-built French-Canadian, primipara, began labor in the afternoon of December 13, 1884, under the care of Dr. C. L. Edwards, of Hyde Park. Notwithstanding vigorous pains and a dilatable os uteri, labor did not advance into the second stage during the night; and Dr. Edwards, wishing a consultation, sent for me early in the forenoon of the next day. The os was then well dilated, and the liquor amnii had escaped.

The breech was presenting, and engaged at the pelvic brim, and the child was male. The position was left posterior, that is, the child's sacrum was towards the left sacro-iliac joint. It was decided to interfere in aid of delivery, and as no foot was within reach of fingers, the bladder was evacuated and full anaesthesia induced with ether. A pair of Simpson's forceps were then applied over the thighs, and attempts at combined traction and rotation were made, the forceps being disengaged and replaced two or three times. This proceeding was so far successful that the breech was brought well down into the pelvis, with the sacrum towards the left acetabulum. Further aid from the forceps seemed impracticable. The finger could now be hooked into the left groin, then into the right; but neither alternate nor combined traction by the fingers effected anything.

A blunt hook was next applied over the flexure of the left thigh, its tip guarded by a finger, and delivery of the lower part of the body thus, without great difficulty, accomplished. The legs were found to be extended upwards, towards the face, and were now easily liberated by successively flexing the knees. The cord pulsated feebly, and, for the safety of the child, no time was to be lost. The left arm had not rotated as had the body; and in carrying the shoulder forward, the better to flex the elbow, the left clavicle was fractured. The arms were successively delivered; but the head, now fully rotated, with the occiput under the pubis, it was impossible to disengage by any justifiable traction. Next, the body was flexed, and the forceps applied to the head from behind the child's back. The head was, by these means, speedily and safely delivered, with but slight laceration of the perineum. Suction at first seemed doubtful, but after active employment of the customary means for a few minutes, respiration was established. Delivery was completed about half-past ten in the forenoon, eighteen hours after the beginning of labor. The child, a large one, did well, and the mother made a good recovery.

<sup>1</sup>Read before the Section of Obstetrics and Gynecology of the Suffolk District Medical Society, January 19, 1887.

A month or two after this, I read in the *New York Medical Journal* for 1885, XLI, pages 177-181, the paper by Prof. William T. Lusk on the subject here considered. The substance of Dr. Lusk's paper has since been included in the latest edition of his book, "The Science and Art of Midwifery." Dr. Lusk's views, as here set down, sustain the course adopted in the foregoing case. He enforces caution in attempting to bring down a foot when the breech is fully engaged in the pelvis. He approves the use of forceps applied to the lateral surfaces of the thighs when the breech is transverse. Failing in this, he favors the fillet or the blunt hook. He recognizes the possible need of forceps to the after-coming head in case of unyielding perineum. In all these respects, his teaching leans towards opposite ground to that of Dr. Robert Barnes.<sup>2</sup>

On review of the case, I am not sure that any different mode of effecting delivery would have been more suitable, or have proved more satisfactory. Cephalic version was impracticable, for the breech was well engaged in the pelvis. Graduated pressure upon the fundus would have accomplished nothing upon a primipara with the soft parts so unyielding.

Probably the hand might have been introduced towards the fundus, the knees, or a knee, flexed, and one or both of the feet brought down; but sufficient traction could not have been made upon one leg within the limits of safety; and if exerted successfully upon both legs together, the soft parts of the maternal pelvis would have been so inadequately dilated that either fatal delay of the head or extensive laceration of the perineum might have ensued. I do not think the fillet could have been used as easily nor as efficiently as was the blunt hook, nor with any advantage in point of safety.

Dr. Barnes says: "Hooks and forceps (to the trunk) will, in all likelihood, either destroy the child or involve its death through the delay arising out of their inefficiency, or they may seriously injure the child."<sup>1</sup>

This statement seems too uncompromising. I see no objection to the trial of either forceps or hook, or to the use of each in succession, provided the adjustment and grasp are guided by proper care and judgment. Dr. Edwards and I felt that we had earned the gratitude of the parents for the substantial results of our efforts, but we failed to receive any evidence of their appreciation. On the contrary, anathemas, he says, were freely launched against me for the accident to the clavicle, without which, the child's life might have been lost.

CASE II. Mrs. C. D., a young American lady, primipara, nervous temperament, rather delicate, but healthy, had gone a month beyond her expected time, when labor began about midnight of November 29, 1885. Presentation was breech; position left anterior.

The first stage proceeded slowly during the night and the day following. Early in the evening of the 30th, the os being fairly dilated, I ruptured the membranes; but the breech did not advance beyond the brim, and I could not feel a foot. Dr. C. E. Stedman kindly responded to my telephonic appeal for aid, and arrived at 9 p. m. At this time, ether, with which I had been familiarizing the patient during pains in a preliminary way, was easily carried to full anaesthesia. It was decided to hasten delivery by securing a foot,

and, with this purpose, the left hand was introduced into the uterus. As had been suspected, the feet were at the fundus, near the child's face. Although the pressure from uterine contraction was strong, the left knee was flexed without very great difficulty, the thumb being in the popliteal space, and the fingers over the tibia, near the instep. The knee was then brought down, and the whole extremity set free.

The same hand was again introduced, and the same process repeated upon the right lower extremity. The upper extremities had to be released successively by flexing the elbows, with the fingers in the vagina. The head gave little trouble, and a full-grown, male infant soon breathed. The cervix and perineum were both torn. Ergot was inserted with a hypodermic syringe, and the placenta expelled by the help of external manipulation. The mother made a good recovery, with partial union of the perineal rent, which Dr. Stedman had united with three deep sutures of silk. The child likewise did well.

This case and the preceding one present obvious points of comparison and of contrast. I think the second case might probably have been delivered by the same method which was successful with the first. I am doubtful whether the first would have resulted safely for the child if the mode adopted with the second had been practised. If, in the second case, as in the first, the forceps had advanced the breech to the floor of the pelvis, and delivery of the trunk had then been carefully completed by fingers, fillet, or blunt hook, it seems to me probable that dilatation of the soft parts at the pelvic outlet would have been so gradually accomplished as to have kept the integrity of the perineum, without increase of peril to the life of the child.

There is the eminent authority of Dr. Barnes<sup>4</sup> in favor of bringing down one foot only, and that the anterior one; and he states that he "has brought a live child into the world by this proceeding on several occasions, where forceps, hooks, and various other means had been tried in vain for many hours." Dr. Barnes says that, by bringing down one foot out of the uterus, you thus break up the wedge; "and this," he repeats, "is the proper thing to do in the first instance." It is my belief that in neither of the three cases here reported could delivery have been effected by any safe and justifiable traction upon *one leg only*, if the other were left reflected upwards. With all deference to his great experience and skill, I must think that cases occur, where, after one extremity only has been brought out, enough of the wedge remains still unbroken to oppose serious obstacles to success by the simple use of the unarmed hand, with which he claims to have been always successful.

CASE III. Mrs. E. F., a strong, stout Irish woman, about twenty-eight years of age, was attended in her second confinement by Dr. H. C. Towle, of Dorchester. Her first child was born footling. Her second labor, October 25, 1886, began about mid-day, and Dr. Towle was called in the evening. At his request, I went to his aid at 1 o'clock, A. M., the 26th. He informed me that the os was well dilated; that the left arm was presenting, and in the vagina; that the back of the child was anterior, and its head in the right iliac fossa. After the patient was fully etherized, Dr. Towle introduced his right hand into the uterus, the

<sup>1</sup> "Obstetric Operations," Chapter XV.

<sup>2</sup> "Obstetric Operations," page 174.

<sup>4</sup> "Obstetric Operations," page 174, et seq.

woman lying on her back. I suggested that he try to reach the right knee or foot, so that rotation should go with version, but he could not find the right extremity, and brought down the left foot, with the toes anterior.

The uterine contraction had been very cramping to his hand; and evidently the child, lying transversely, by the joint influence of the traction and uterine action, had been rolled over before the full effect of the traction had secured version. The child now lay with its back posterior, and the sequel showed that probably both lower extremities were reflected towards the face at the beginning of labor. If this were so, the right foot probably lay behind the child's right shoulder, where it could not have been reached unless the knee could have been first flexed.

The diagram illustrates the supposed position before it was changed by interference.

The left foot having been secured by tape, Dr. Towle again introduced his hand, but it was so cramped that he withdrew it, and asked me to take my turn. After placing the woman on the left side, with the hips near the edge of the bed, I passed my hand nearly up to the fundus uteri, and found that the right leg was extended, so that the foot must be near the face. The knee was first flexed, and then, at the same time that the leg was brought down, the body, by the convenient leverage of the thigh, was rotated to the left, bringing the child's back anterior. The delivery was then readily completed in the usual manner. The child, a full-grown male, required some attention before respiration was established. The placenta was adherent in the uterus anteriorly, and was carefully delivered by the hand of Dr. Towle. The mother and child did well.

As trunk-presentations, and those of the breech having the legs reflected upwards towards the face, are both rare, perhaps this case, combining the two abnormalities, may, as a matter of record, be unique. By a reasonable application of the law of averages, I suppose there should be about four such cases in each million births.

My reasons for supposing the child's position at the beginning of labor to be that represented in the diagram are these:

*First.* The ease with which Dr. Towle reached the left foot, and his failure to find the right one at either trial.

*Second.* The improbability that the right leg, if flexed at first, would, in the process of, first, rotation, next, version of the trunk, have become extended.

*Third.* Reversely, the probability that the right leg, if extended at first, would remain so during and at the completion of rotation and version.

*Fourth.* The strong probability that, if either leg is extended, both legs are so.

#### REPORT ON MEDICAL CHEMISTRY.

BY WILLIAM R. HILLS, M.D.

##### THE POISONOUS ACTION OF POTASSIUM CHLORATE.

The view first advanced by Fourcroy and Alyon, that potassium chlorate, when taken into the system, gives up part of its oxygen, has, since the investigations of Binz<sup>1</sup> and Marchand,<sup>2</sup> been generally accepted in explanation of the poisonous action of the salt. B. J. Stokvis<sup>3</sup> contradicts this view, basing his opinion upon investigations of W. C. Kimmyser,<sup>4</sup> of H. C. M. v. Gorcom, and of his own.

Kimmyser has investigated the elimination of the chlorate in his own urine, and in that of rabbits and dogs. He found that, of four grammes of sodium chlorate, there was eliminated unchanged, in his own urine, 2.277 grammes, and in the urine of a dog, 3.618 grammes. In the urine of rabbits, to which one and sixteen grammes had been administered, he found 0.896 gramme and 13.53 grammes, respectively. On the days when the chlorate was administered, there was an increased excretion of chlorides (and usually of urea); but this increase, according to the author, is not to be attributed to a reduction of the chlorate, but to a drain on the system, since, on the following days, there was a diminution in the amount of chlorides excreted. The chlorate behaves, in this respect, like sodium nitrate, as Kimmyser determined by experiments on rabbits, whose urine had been rendered free from chlorides by inanition. He, therefore, concludes that a reduction of the chlorate in the system is not proven. Such reduction is also denied by Stokvis, Isamburt, Rabuteau, and Von Mering. The small amount of chlorate unaccounted for in the urine is explained, according to Stokvis, by slow elimination, by passage into the secretions, which takes place even after the ingestion of small doses, by reduction in the urine, and by experimental errors. Kimmyser finds that, when urine containing one per cent. of sodium chlorate is allowed to stand twenty-four hours at 20° C., twenty-four per cent. of the salt is reduced. This reduction does not take place at 0° C., or in acid urine, and is less when the urine has been boiled. It depends, according to the author, on beginning putrefaction. Reduction in the blood depends on complicated putrefactive processes, which take place only when the blood loses its vitality. There is formed, in this case, methæmoglobin and hæmatin. An increased temperature favors the process, but a reduction of the whole quantity of chlorate present takes place only rarely, and when the amount of salt is small.

The appearance of the blood observed in fatal cases of potassium-chlorate-poisoning is attributed, by the author, to post-mortem changes. The change does not take place in living blood; for the intravenous in-

<sup>4</sup> Académ. Proefschrift, Amsterdam, 1884.

jection of sodium chlorate in rabbits was followed by the appearance of albumen and sugar in the urine, but, in very acute cases, no methæmoglobin, which, in these animals, passes very easily from the blood to the urine. In protracted cases, however, an active hyperæmia of the kidney is set up, and the blood-corpuscles which pass into the urine are the source of the methæmoglobin which has been found in the urine in many cases of chlorate-poisoning.

The poisonous action of potassium chlorate is due, according to Jacobi, to paralysis of the heart, and this is attributed, by Leichtenstern, to the action of the metal. It does not differ, according to Stokvis, from the action of potassium chloride or sulphate in corresponding doses. According to these authorities, symptoms of poisoning take place only when the dose is large, or the solution concentrated, or when a considerable quantity has been taken into an empty stomach in the form of small doses, frequently repeated. Sodium chlorate acts, according to Van Gorcum, precisely like sodium chloride, whether administered by the mouth, or by the intravenous injection of concentrated solutions.

#### CARBONIC OXIDE; OXALIC ACID.

Gugliò<sup>4</sup> finds that neither of these bodies suffer oxidation in the system. Both are eliminated unchanged, the former with the expired air, the latter with the urine.

#### DIGITALINE.

Ph. Lafou<sup>5</sup> reaches the following conclusions, as a result of his study of this substance:

(1) Digitaline is absorbed slowly. (2) It is not eliminated by the kidneys. It could not be detected in the urine. (3) It does not appear to localize itself, at least, in the form of digitaline, in any particular organ, either in acute or slow poisoning. It is not cumulative. (4) It is not sensibly modified in the digestive apparatus. It appears to undergo a complete transformation in the circulation. This change is probably effected by some oxidizing agent. (5) Digitaline offers a relatively great resistance to both physical and chemical agencies, to various ferments, and to putrefaction.

#### THE POST-MORTEM DETECTION OF CHLOROFORM.

Dr. Charles Leudeking,<sup>7</sup> of St. Louis, the chemist employed in the Maxwell case, obtained, by chemical analysis of the lungs of Maxwell's victim, very decided reactions for chloroform. The analysis was made ten or twelve days after death, and the body was in a high state of decomposition. As the great volatility of chloroform would seem, *a priori*, to preclude the possibility of its detection so long after death, and as, at the same time, there was considerable doubt expressed as to the reliability and accuracy of the experiments, the chemist determined to decide the matter by direct experiment, and so set at rest all doubt.

Dogs of from fifteen to twenty pounds' weight were destroyed gradually, by the administration of chloroform through the lungs, in from five to ten minutes. Then the carcasses were allowed to stand in summer's heat, or at the temperature of the room, for different periods of time, and finally, the lungs removed and tested for chloroform by the Ragsky method. A very

decided reaction for chloroform was obtained in each experiment.

Three experiments were also made to determine whether or no any substances are generated by the process of decomposition, which might give reactions similar to those of chloroform, and thus lead to erroneous conclusions. The results in each case were negative.

The conclusions reached were the following:

(1) By the process of decomposition, no substances are generated which can vitiate the tests for chloroform by the Ragsky method. (2) Chloroform, when it has caused death by inhalation, can, with certainty, be detected in the body four weeks after death; and, notwithstanding its volatility, it is certainly retained in the viscera in large amount during this time.

On the strength of the Ragsky and Hoffman tests, the author gave it as his sworn opinion that the deceased Preller had chloroform in his viscera; and Maxwell, after the lapse of a year, confessed that chloroform had been the cause of death.

In explanation of the retention of chloroform in the tissues for so long a time after death, the author calls attention to the investigations of R. Dubois,<sup>8</sup> who finds that chloroform penetrates into the interior of the tissues, and becomes substituted for normal water. This is not a phenomenon of desiccation or osmosis; a true affinity comes into play, protoplasm absorbing the vapor of the anæsthetic, and expelling a certain quantity of water.

Chancel and Parmentier<sup>9</sup> have proved that chloroform has a very decided affinity for water. The author allowed to stand open a flask, containing water holding a small quantity of chloroform in solution. After two weeks' time, the chloroform reactions could still be obtained without difficulty.

The author calculates that the quantity of chloroform in the lungs of a man of one hundred and fifty pounds' weight, rendered insensible from its inhalation, would be about one-half gramme—an abundant amount for its detection. This calculation is based upon the experiments of Grehaut and Quinquaud,<sup>10</sup> who found the amount of chloroform necessary to produce anæsthesia to be, at least, one gramme to every two liters of blood.

#### RESISTANCE OF COLCHICINE TO PUTREFACTION.

Ogier<sup>11</sup> has made experiments which confirm the result previously obtained by Dannenberg. Three dogs were poisoned by colchicine: one by 0.5 gramme injected subcutaneously; a second by 0.1 gramme administered in the same way; the third by 0.5 gramme introduced into the stomach. The bodies were buried, and exhumed five and one-half months later. In the extracts from the various organs Ogier obtained satisfactory reactions for colchicine with nitric acid (specific gravity 1.4), and with ammonium vanadate recently dissolved in sulphuric acid. The organs of two of the animals were in an advanced state of decomposition.

#### POISONING BY SILVER SALTS.

Krissinsky<sup>12</sup> reaches the following conclusions, based upon an examination of the organs in three

<sup>4</sup> *Archiv der Pharmacie*, 1886, p. 1032. Abstract.

<sup>12</sup> *Journal de Pharmacie et de Chimie*, 1886, p. 517.

cases of poisoning in the human subject, and upon experiments with animals:—

(1) The black granulations met with in the tissues are composed of an organic compound of silver, the exact nature of which is not fully known. (2) The silver is first deposited in the coats of the bloodvessels and only later is found in the connective tissue. (3) The accumulation of the metal in the walls of the vessels leads to deeply-seated changes and degeneration. (4) The black granulations are found in the epithelium as well as in the endothelium, in the afferent as well as the efferent vessels of the Malpighian corpuscles, and in the lymphatic corpuscles of the blood. (5) In the liver the silver is deposited principally in the radicles of the portal vein and of the intralobular veins; but it is also found in the capillary plexuses uniting the two systems, as already determined by Huyet. (6) The deposit of silver in the tissues has been observed in cases of poisoning of forty-eight hours duration; but it did not then possess the characteristic dark color, and only acquired this under the influence of sulphuretted hydrogen. (7) The most abundant deposit of silver is found in the cells of the medulla of the bones.

#### DETECTION OF MERCURIC CHLORIDE IN ORGANIC MIXTURES.

Mercuric chloride, when mixed with organic matter, is slowly reduced to the metallic state. This reduction, according to Lecco<sup>13</sup> is usually complete within six weeks. If the mixture is boiled the reduction takes place immediately. In order therefore to detect corrosive sublimate as such, in foods and similar mixtures, the latter must be examined early, and must be treated with cold alcohol and ether before heating.

On distilling foods, etc., containing finely-divided mercury thus formed by reduction, a portion of the mercury passes over with the steam.

#### MITTSCHERLICH'S TEST FOR PHOSPHORUS.

Porlstorff and Mensching have shown that, in the employment of this test in toxicological investigations the luminosity of the phosphorus vapor is destroyed, if the substance under examination contains corrosive sublimate. They now find that this is the case with other mercury salts.<sup>14</sup> The salts of copper have no effect on the luminosity. The authors conclude that the corrosive sublimate volatilizes in part, and that a reaction takes place between this and the phosphorus vapor; some reduced mercury passes over into the distillate, together with a small amount of phosphoric acid, the greater part of the latter, however, falling back into the distilling flask. The action of other soluble mercuric salts in preventing the luminosity, is explained by their conversion to corrosive sublimate by the chlorides present. Calomel appears to be decomposed by albuminous matters into corrosive sublimate and metallic mercury. Bernbeck<sup>15</sup> states that copper sulphate interferes to some extent with the detection of phosphorus by this test. This statement derives its importance from the fact that copper sulphate is the most useful emetic in cases of phosphorus poisoning. When this emetic has been administered, the particles of phosphorus may become coated with a crust of reduced copper sufficiently thick to prevent the solution and oxidation of the phosphorus when

the vomitus or contents of the stomach containing it, are subjected to analysis. The indications are to make the materials more strongly acid before commencing the analysis.

Mankiewicz<sup>16</sup> states that small amounts of phosphorus may easily be overlooked in the presence of carbolic acid. No luminosity could be detected when two hundred grammes of a three per cent. solution of carbolic acid, containing two milligrammes of phosphorus were distilled. The luminosity was plain, however, when the same solution containing five milligrammes of phosphorus was examined.

#### SNAKE POISON.

R. N. Wolfenden<sup>17</sup> finds that the toxicity of the venom of the Indian cobra (*Naja tripudians*) is not due to any bacterium or living organism, nor to any alkaloid—alkaloids and ptoamines are entirely absent from the venom—nor is it due to any cobric acid such as was described by Blyth. The author finds that the crystals to which the name cobric acid was given, are in reality, composed of calcium sulphate. The venom, however, is sometimes faintly acid, sometimes neutral. The poisonous properties of the venom are due to its proteid constituents, which are as follows:—

(1) Globulin, which is always present and kills by causing asphyxia. (2) Syntonin, which is precipitated by magnesium sulphate with the globulin. It dialyses through parchment paper to some extent. The poisonous property of the acid dialysates is due to this proteid, not to cobric acid. Its action is similar to that of the globulin, but less intense. (3) Serum albumin; this is also toxic, producing paralysis. (4) Traces in some specimens of hemialbumose, and questionable traces of peptone are regarded as accidental.

With regard to the venom of the Indian viper (*Daboia Russellii*), it is found to be of the same reaction as that of the cobra; but here again there is no toxic acid, alkaloid, or living organism, but the proteids are the poisonous constituents; these are three in number:—(1) Globulin, which greatly preponderates as in cobra venom; (2) Serum albumin in small amount; (3) A proteid which possesses many of the properties of an albumose. True peptones do not occur, and it is probable that the substances described by Weir Mitchell and Reichart in crotalus, copperhead, and moccasin venoms as peptones are in reality albumoses.

(To be continued.)

## Hospital Practice and Clinical Memorandum.

### A CASE OF DIFFICULT LABOR.<sup>1</sup>

BY EDWARD REYNOLDS, M.D.

On September 24, 1886, in the absence of Dr. Boardman and Dr. Green, I was called to the Boston Lying-in Hospital to see a patient with the following history:

F. L., twenty-nine years of age, married, and a native of Ireland, had miscarried once, but was at term

<sup>17</sup> Archiv der Pharmacie, November, 1886, p. 936. Abstract.

for the first time. Labor began at 6 P. M., of the 22d, and she entered the hospital the same evening, when her condition was as follows: The os admitted the finger-tip; the membranes were ruptured; the position was O.L.A. The fetal heart was strong and regular at 132. The head was within easy reach of the finger; the pains were slight and infrequent.

During the night the cervix was taken up, and the os reached the size of a ten-cent piece; but, as the pains were short and "nagging," and the os wired, chloral, gr. xv, was given at 3 A. M., and repeated twice, at short intervals. No very marked effect followed; and at 10 A. M., the pains being almost continuous, short, and ineffectual, she was etherized to snoring anaesthesia for about five minutes. Under ether, the os relaxed and dilated to the size of a fifty-cent piece; the patient slept about an hour, and had strong pains, with good intervals, during the next twelve hours, but without effect upon the os; the pains then died away, becoming short and infrequent. The os again became rigid, and recontracted slightly, and in spite of two fifteen-grain doses of chloral at 11 and 11.30 P. M., this condition lasted throughout the night; but as she slept well in the intervals, and did not appear exhausted, I was not sent for till 6 A. M. (September 24th).

The patient had now been in labor about thirty-six hours. The os was small, rigid, and tightly applied to the head, which was low and not easily movable. The patient had become languid and indifferent, and was decidedly irritable when roused; but as the maternal pulse and temperature were normal, and the fetal heart remained strong and regular, there seemed to be no urgent reason for interference. There was, however, a prominent caput succedaneum; and the fact that pains of sufficient strength and regularity to cause its presence had persisted for twelve hours, and had then died away, and been succeeded by feeble and irregular contractions, led me to infer that some efficient obstacle existed, and to believe that, at the least, a thorough examination under ether was indicated.

Under ether, the os was soft and dilatable, and the head, though still within the reach of little more than the first joint of the forefinger, was freely movable; the relaxed condition of the os now made it possible to pass two fingers high up around the head, and the promontory of the sacrum was easily reached, the greatest diameter of the head being still above it. I then measured the pelvis, with the following results:

Distance between Iliac spines	9½ in.
Distance between Iliac crests	10½ "
Extern. Conjugate	7½ "
Diag. Conjugate	4½ "
Length of Symphysis	2 "
Inclination of Symphysis	much diminished.

It was evidently a flattened pelvis, with probable diminution in all diameters; and, after taking into consideration the diminished inclination of the symphysis and its increased length, I was inclined to estimate the true conjugate as 3½ inches.

There was as yet, however, no sufficient indication for so serious an operation as delivery through a rigid os. On passing the fingers up along the anterior uterine wall, the lower segment was found tense and thin; and, at least two inches above the symphysis, I found a well-defined contraction-ring. On bimanual examination, the difference in thickness between the upper and lower uterine segments was extremely marked, being, at least, three-eighths of an inch. Finally, it

was possible to determine the position of the contraction-ring by external palpation alone, the abdominal walls being thin.

The whole case was now clear: The head was too large to pass the flattened brim; but the decreased inclination of the symphysis brought the anterior end of the obstetrical conjugate so low, that, after the head had been subjected to the molding processes, that portion of it which lay anteriorly was almost at the vulva, while its greatest diameter was, in reality, above the superior strait.

The long-continued efforts of the uterus, exerted against an insuperable obstacle, had produced a state of tonic spasm of the uterine muscle, in which the cervix clasped the presenting part, while the head, as a whole, was pressed firmly against the pelvis by the uterus above. The lower uterine segment had become markedly thinned, and the woman was in a critical condition, in spite of the absence of the usual signs of exhaustion.

The question of treatment now presented itself. It was evident that to leave the case to nature meant ultimate rupture of the uterus; and, the child being in good condition, that the choice lay between the application of high forceps and version. Abdominal palpation proved that a sufficiency of liquor amnii remained; and as I felt sure that it would be extremely difficult to bring so large a head through a flattened pelvis by means of forceps, in addition to the difficulties in applying them with the head above the brim and through the undilated os, I decided to dilate and turn.

The os was quite resistant. Its dilatation occupied nearly 50 min.; and, though the child turned easily, the cervix closed so tightly upon the breech that I was obliged to make the extraction very slow, in deference to the risks to the mother.

There was no other real difficulty in the extraction; and the child, which weighed 8½ pounds, though born asphyxiated, was resuscitated without much difficulty. Convalescence was uninterrupted, and mother and child were discharged, well, on the fourteenth day.

This case was interesting to me, as illustrating the importance of watching the character and behavior of the pains, in addition to the condition of the mother. Here was a woman who might easily have appeared, on superficial examination, to be merely undergoing a long first stage. The pains were slight and infrequent; the head was apparently well into the pelvis, and more or less firmly fixed in position; the os was rigid and resistant; the fetal heart was strong and slow; the mother's pulse and temperature were normal; and she was resting well between the pains. It is in just such cases that an expectant policy is often pursued, for fear of doing meddlesome midwifery by interference with the os during the first stage; but the fact that pains of sufficient strength and regularity to produce a large caput had failed to dilate the os, and had died away, to be succeeded by faint and infrequent contractions, made it at least probable, that delivery was delayed by some obstacle other than the condition of the os; and examination under ether showed that, in spite of her normal pulse and temperature, the woman was in a condition in which extreme exhaustion, and probably rupture of the uterus, must have supervened within a few hours; while the relief of this condition, by the operation of version, was as yet by no means difficult or extremely dangerous.

## Reports of Societies.

### SUFFOLK DISTRICT MEDICAL SOCIETY. SECTION OF OBSTETRICS AND GYNÆCOLOGY.

ROBERT B. DIXON, M.D., SECRETARY.

JANUARY 19, 1887. DR. A. D. SINCLAIR in the chair.

DR. J. S. GREENE, of Dorchester, reported

THREE CASES OF LABOR, TWO BEING BREECH, AND THE OTHER ARM PRESENTATIONS, WHERE THE ARMS WERE EXTENDED AND THE FEET WERE NEAR THE FACE.<sup>1</sup>

DR. E. W. CUSHING mentioned the case of the son of the Crown Prince of Germany, at whose birth Ed. Martin was the accoucher. The clavicle or humerus was broken, and partial paralysis of the arm ensued, preventing, it is said, the power of handling a sword.

DR. EDWARD REYNOLDS reported

#### A CASE OF DIFFICULT LABOR.<sup>2</sup>

DR. SWIFT said he had been very much interested by the paper, as he had had two quite similar cases. One where the pelvis was flattened, and the other a universally contracted pelvis. In both labor was allowed to go on for a long time without the condition being suspected, the patient in each case, to all appearances, being well formed.

He thought that when we were engaged for a case of confinement in a primipara the pelvis should always be measured as soon as possible.

It seemed to be the opinion that contracted pelvis was very rare in this country, but he thought the condition must be getting more common, for he had met with several cases lately.

DR. FARLOW said he was much interested in Dr. Reynolds's allusion to the thinning of the lower uterine segment. Particular attention had been called to this point by Bandl, of Vienna, whose pamphlets on the subject had excited considerable discussion. When, in a case of tedious labor; it is found that the lower portion of the uterus is thinning, especially anteriorly, we should at once try and make out whether this thinning is not due to the continued ineffectual attempts of the uterus to expel a child through a narrowed pelvis. Steps should at once be taken to ascertain the pelvic diameters, if possible. It is this lower and thinned portion of the uterus that rupture usually takes place, and not at the fundus, and forceps or version should be considered without delay. Very little has been said or written here about this condition, but in Vienna it has received considerable attention. In regard to version, Dr. Farlow mentioned a case of narrow pelvis which he had recently had, in which ordinary forceps and axis-traction forceps had failed, and where version and forceps to the after-coming head had been successful.

In answer to a question of Dr. Fifield, as to how far Bandl's ideas on the subject of a ring above the os internum are accepted, Dr. Farlow thought that less reliance was placed in its existence and significance than Bandl had hoped, but that such a ring often existed Bandl's plates seemed to prove beyond doubt.

DR. EDWARD REYNOLDS, in answer to a question of Dr. Irish, said that in a flattened pelvis with the

greatest diameter of the head still above the brim it was better to turn, because the forceps would compress the head laterally and increase the length of the antero-posterior diameter. His experience with version in the flattened pelvis had given him confidence in that operation.

DR. REYNOLDS thought that the pelvis should be measured in all cases where circumstances permitted it. He has had experience with some ten or twelve cases of flattened pelvis. His method is to measure internally with two fingers, getting the distance between the pubic arch and the sacral prominence during the first examination in labor, and to make more extended measurements if there seemed to be reasons for it.

DR. BLODGETT stated that he had had one case, in which the pelvis was apparently similar in shape to the one reported in the interesting paper by Dr. Reynolds. The child in this instance was large and very high up and, after some delay, the services of the senior Dr. Reynolds were obtained in consultation. He fully concurred in the opinion of the condition of the pelvis, and after some further delay the high forceps were applied. In spite of the most strenuous efforts, no apparent advantage resulted from this procedure, and it was considered advisable to perform version. This was with some difficulty accomplished and proved the means of comparatively rapid, though by no means of easy delivery. The maternal passages were considerably lacerated, and there was dangerous flooding, with imminent peril to the life of the mother. The perineum was wholly restored without operation, and the mother has since been again confined with no serious complication so far as heard from. Dr. Blodgett feels that in a similar case he would resort to version at an earlier stage in the case, both in the hope of averting a certain degree of augmented danger to the mother, as well as of affording the possible means of saving the life of the child, which is often sacrificed by too long delaying necessary operative interference.

DR. CUSHING spoke of the custom in Vienna of waiting ten to fifteen minutes during the operation of version when the child had been turned, so that the foot came outside before completing the delivery. It is much better for the child, and less children are born asphyxiated. During the process of turning the child's heart becomes rapid, fluttering and irregular, and it requires ten minutes to quiet it. And ten minutes or often more are necessary for the uterus to relax its contractions which hold the child. He had a case of this kind and could not deliver the head, but in about twenty minutes it came out easily. Dr. Morland had a similar case. The head was gripped and could not be delivered, and both woman and child were lost.

DR. A. E. McDONALD mentioned a case, which he had had about eight years ago, where it was the woman's last chance, owing to her age, of having a living child. Being over-anxious on this account, the body was immediately brought down, but the head was arrested, by being firmly grasped by the uterus, defying all reasonable efforts at delivery; but, after a few minutes, the spasm subsided, and the head was easily delivered, but the child was beyond resuscitation. Since then it has been his custom to wait, after turning, some ten or fifteen minutes, before pressure is made on the cord, to give opportunity for the tonic uterine spasm, caused by the manipulation, to subside, as delivery of the head is then more easily accom-

<sup>1</sup> See page 325 of the Journal.

<sup>2</sup> See page 329 of the Journal.

plished. He said that he had had five or six cases in which he had applied forceps to the after-coming head in flat pelvis, in none of which he had met with any difficulty.

DR. FIFIELD mentioned a case of a woman, pregnant to term but not in confinement, to whom he was called about midnight, on account of retention of urine. No pain. She had not passed urine since noon the day before. Examination of the abdomen showed a distended bladder. Per vaginam the os was found partially dilated and membranes were to be felt. An effort was made to pass a silver catheter but an obstacle, apparently the head, presented. He tried a gum-elastic catheter in vain. He then went home and obtained several small olive-pointed catheter bougies, and, after trying several, he succeeded in passing one, about a No. VI. The urine came out in fast falling drops, to the amount of two and one-half cupfuls; some more was lost. Pains then started up at long intervals, and in six hours he ruptured the membranes. The pains then increased and at nine o'clock the next morning high forceps were applied and the child delivered. A full-sized catheter was then passed. If he had not had the small catheter it would have been necessary to have aspirated. He said he should not hesitate to aspirate once or twice, but should not care to repeat the operation.

He considered the relief of the bladder of two-fold importance. He recalled a case which he saw in consultation, where the woman had not passed urine for a long time. The physician in attendance had tried forceps in vain. Dr. Fifield passed a catheter and the delivery followed at once.

He spoke of an English physician who said he had prevented flooding by passing the catheter after delivery of the placenta; it permits the uterus to contract.

DR. R. J. P. GOODWIN mentioned a case of a prostitute to whom he was called to remove the fragments of a broken glass syringe, which she had been using for masturbation. About one-half of the syringe was broken in fragments within the vagina, and he was in a quandary what to do. If he inserted his finger to remove the glass he would cut it, and the soft parts might be injured. With a Davidson syringe he pumped the vagina full of olive oil, holding the lips of the vulva firmly closed, and then telling the woman to stand, and spread her legs open, after stamping upon the floor to allow the glass to gravitate downwards, he let go the vulva and out came the glass fragments and oil together, without the slightest injury resulting therefrom.

DR. FIFIELD spoke of a woman to whom Dr. Appleton was called in Florence, to remove a broken syringe. He pumped the vagina full of gruel with beneficial results.

#### ROXBURY SOCIETY FOR MEDICAL IMPROVEMENT.

C. F. WITHINGTON, M.D., SECRETARY.

MEETING March 24, 1887.

DR. CALL in the chair.

DR. COTTING reported a case of

#### RADICAL RELIEF OF INFLESHED TOE-NAIL.<sup>1</sup>

DR. GOSS said that he had often seen this operation

<sup>1</sup> See page 324 of this number of the Journal.

performed, and in some very desperate cases. He remembered the instance of a young gentleman, who had been quite crippled for a long time by the disease, and had submitted to many and various kinds of treatment, some quite severe, without avail. At the time when seen he was completely laid up. Both great toes were hugely swollen, and intolerably painful—with foul, open, fungoid ulcerations on the sides of each.

Four very large and thick slices were removed at the same time. Relief was immediate, and the result entirely successful. The toes became symmetrical and shapely, so much so that when, a year or two after, he underwent a thorough, from head to foot, examination for a Naval Commission, the examiners apparently failed to detect that he had ever been subject to the malady. He subsequently reported that he had found that he had as good-shaped and as useful toes as any other officer in the service.

DR. GOSS recalled another case also cured by this method where the ailment had recurred after the evulsion of the nail. He never knew of a case of failure by Dr. Cotting's method.

DR. WITHINGTON spoke of the cicatrix he had examined in one of Dr. Cotting's old operations, as having drawn all the soft parts so thoroughly away from the edge of the nail as to preclude any possibility of the lesion ever being reproduced. The shape of the toe was good, and, apparently, had been essentially improved by the operation.

DR. SEAVENS asked Dr. Cotting if he had not formerly advised the including of a slip of the nail in the slicing off of the side of the toe.

DR. COTTING replied that he had not;<sup>2</sup> but that he had said that, while not necessary, if, in attempting to secure quite enough, the edge of the nail should by chance happen to be included in the cut, no harm would arise therefrom.<sup>3</sup> It is better to remove too much than too little. By force of habit he generally operated by one continuous rapid stroke of the knife,—an important point in his first cases before the discovery of anaesthesia.<sup>4</sup> Now, some operators, in order to secure the exact amount predetermined on, pass a double-edged knife midway by the side of the nail and downward through the toe, very deliberately (the patient being under ether) cutting out both ways, forward and back. By so doing the nail is not put to any risk whatever. Nevertheless, the edge of the nail should be completely exposed throughout its whole length.

DR. SEAVENS asked also if the wounds were not sometimes very slow in healing. He had had one patient who was greatly annoyed because of long delay in this respect.

DR. COTTING replied that he had never known of any tedious delay; that, in his experience, the healing was as rapid usually as in other wounds of similar gravity. Besides, the tendency of the wound is always towards healing; that of the disease seldom, if ever.

DR. GARCEAU, who had performed this operation many times, now employs as a tourniquet a small rubber tube (such as usually comes with nursing bottles). After compression is effected, he removes the tube in part, from below, leaving the other portion on until the operation is over, and the dressings applied. He touches the surface of the wound with the perchloride

<sup>2</sup> Boston Medical and Surgical Journal, May 17, 1866, p. 340.

<sup>3</sup> Ibid, Jan. 2, 1873, p. 5.

<sup>4</sup> Ibid, June 25, 1879.

of iron. Patients thus treated, have been able to walk about at once in soft slippers; and some have gone to their business the day after the operation. With him Dr. Cotting's method has always succeeded. He had operated on persons, half a dozen at least, of over seventy years of age, without a failure or an accident.

#### THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, March 17, 1887.

DR. T. MITCHELL PRUDDEN read a paper on

**BACTERIA IN ICE, AND THEIR RELATIONS TO DISEASE, WITH SPECIAL REFERENCE TO THE ICE SUPPLY OF NEW YORK CITY. AN EXPERIMENTAL STUDY.**

He first gave a description of the recent method of the biological analysis of water, and then showed that by it we could detect with great certainty the presence of bacteria, some species of which are capable of giving rise to the most serious disease. When we had determined the number of bacteria present in water or ice, however, a careful consideration of other conditions was still imperative in order to determine whether the water or ice was fit for use. The popular impression that water purifies itself in freezing was only partly true, so far as the bacteria are concerned. The partial purification from bacteria was accomplished, not by their expulsion from the water, but by the death of a certain proportion of them; so that if the bacterial contamination of the water were extreme, or were largely made up of the more hardy species, the ice formed from it, even though quite transparent, might still contain large numbers of the living germs. His experiments showed that bacteria of different species possessed differing degrees of vulnerability to the action of low temperatures. Certain species which were capable of producing serious and even fatal diseases in man—the bacillus of typhoid fever and the common bacterium of suppuration, for example—were capable of resisting a prolonged low temperature, with the destruction of only a part of the individuals thus exposed. In the case of the typhoid fever germ the exposure has lasted seventy-seven days. The resisting capacity of the different species was found to vary with the vitality of the individuals, the degree of temperature, and the time of exposure; while alternate freezings and thawings sufficed to entirely exterminate in a short time all species experimented on—even those which could endure a sustained low temperature for long periods. In this investigation, data were gathered which seemed to justify the conclusion that in the freezing of natural waters there may be a purification from bacteria amounting to as much as ninety per cent. The effect of freezing on water was shown to be comparable to that of filtration, but with this vital difference, that whereas by filtration, all forms of bacteria are removed in approximated equal ratio in the process of freezing, which acts as a sort of relative filtration, some of the most dangerous forms may be retained, while others are destroyed.

The supply of ice for New York city was principally derived from a series of naturally excellent lakes or ponds, and from the Hudson River; the latter constituting by far the most important source. This was a great tidal stream rich in sewage pollution. The

ice was harvested mainly between Troy and Poughkeepsie, and in the upper part of this region the river received the entire sewage of the large cities of Albany and Troy; to say nothing of such smaller places as Cohoes and Lansingburgh, and the contaminations which the Mohawk River brought from the West. While, however, the conditions on the upper Hudson did not seem, during the ice-forming season, to be such as would favor purification from organic matter by oxydation, they did yet seem to be theoretically and were shown to be practically favorable to a considerable degree of spontaneous purification from bacteria by sedimentation. Still the limits and extent of this purification were yet to be determined.

Coming to the actual analysis of the ice brought from the Hudson and from the lakes and ponds referred to, it was found that there was a much greater number of bacteria in the snow-ice than in that which is clear or moderately full of bubbles. The species of bacteria were much more varied and abundant in the river-ice than in that from the other sources, while in both there was a considerable proportion of the relatively harmless water bacteria. While the number of living bacteria varied greatly, not only in different parts of the same block of ice, but also in ice from different parts of the river, and from different lakes and ponds, the average number was considerably greater in ice from the river than from the lakes and ponds, even when Albany ice, which is the worst of all, was excluded from the estimate. It was found, also, that the average number of bacteria in ice from all sources taken together, was far beyond the general standard which even a moderate degree of purity would allow.

We now stood face to face, Dr. Prudden went on to say, with the most difficult and at the same time the most important part of this study, namely, the interpretation of its results and the suggestion of its practical lessons. The natural situation of the lakes and ponds was good, and evident sources of contamination with sewage and excrementitious material could be largely excluded. Whether in the case of Rockland Lake, which was the most important source of this character, certain dwellings on the hillside near by might furnish a source of absolute danger in the event of an outbreak of typhoid fever there or not, he was not prepared to say. As regards the lake and pond ice, in general, we might conclude that, although the product from some of them contained a larger number of living bacteria than was consistent with the highest hygienic standards, the conditions could be readily changed so as to render them quite unimpeachable; while in some cases, notably in the smaller ponds, the ice, so far as his analysis showed, was well within the ordinary standards of excellence.

The Hudson River, on the other hand, stood on an entirely different basis. Now, given the Hudson River ice as we found it, and knowing what we did of the character of the stream, what actual danger had we to fear from the use of the ice for drinking purposes? A considerable number of the bacteria which it contained were undoubtedly the relatively or absolutely harmless species which may exist in any natural river or spring water; but a large number might, with equal certainty, be assumed to originate from animal excreta. Here, again, it was scarcely to be doubted that a considerable proportion of the bacteria existing in sewage, and coming from human and other animal

excreta, and the varied putrefying fluids which form a prominent ingredient in the water of populous towns, might not be positively dangerous if taken into the body, in moderate quantities, in drinking-water. So far as such bacteria went, it would seem to be largely a matter of taste, on the part of the consumer, whether or not he used such material for drinking purposes. On the other hand, in every large town, like Albany or Troy, and in smaller towns in lesser degree, a considerable quantity of bacteria, which are the cause of serious disease, were more or less constantly passing into the sewers in the excreta and other waste; and here, the use to which this diluted sewage should be put ceased to be a matter of individual preference, because the interests of the public health were involved.

There were some varieties of diarrheal disturbance, sometimes severe and sometimes mild, which often seemed to depend upon impure water or ice; but whether they were occasioned by sewage or other bacteria, or by organic matter, or by both, was not yet certain, so that this class of cases could be left out of view. Fortunately, cholera and anthrax, both bacterial diseases transmissible by drinking-water, were not ordinarily present in the sewage of the region under consideration; so that these diseases, although they could not be ignored by those having the public health in charge, did not fall within the scope of the present study. But there were two very common and very important bacterial diseases which were almost constantly present in large towns, like Albany, and frequent enough in villages, like those along the shores of the Hudson: These were typhoid fever and the affections associated with acute suppurative, and the so-called blood-poisoning from wounds or pyæmia. Now it was, unfortunately, true, as Dr. Prudden's studies had shown, that the bacteria causing these two forms of disease were markedly resistant to the temperature at which ice forms. The most important of these was the typhoid bacillus. The health statistics of Albany did not show the number of cases; but, for the past three years, the number of deaths from typhoid fever in that city during the ice-forming and harvesting months, that is, from December to March, had averaged about sixteen for each year. Reckoning the death-rate at thirty per cent. (which was unusually high), there would be, each year, about fifty cases of typhoid, whose excreta would pass directly into the Hudson River from Albany alone during the ice-forming season. He had been informed that, in Albany, as in most American towns, there was no systematic disinfection of the typhoid discharges, either in hospital or private practice. The bacteria of typhoid fever had been repeatedly shown to be capable of living for a considerable time in water; and, according to Frankland and other authorities, they might even proliferate in water. Dr. Prudden had also found, as has been stated, that when frozen up in ice, a certain proportion of these bacilli might live on for long periods, ready, when thawed out and placed under favorable conditions, to go on growing or proliferating, just as before their hibernation.

Here, then, as it seemed to him, was the positive source of danger in the use of the Hudson River ice directly for drinking purposes, without some form of filtration; at least, until it could be ascertained at what distance, if at all, below Albany and other towns, whose sewage drains into the river near the ice-fields, a safe degree of bacterial purification of the water by

natural means might have occurred. The typhoid bacillus had not been detected in the Hudson River ice; and to detect it, even though present in considerable numbers, in its mixture with other species, and in the large dilution which exists, presented very great practical difficulties. It had been found in water suspected to be the cause of certain local outbreaks of typhoid fever, but the conditions for its discovery were much more favorable than in the present case.

If, on the other hand, we looked at the cases of typhoid fever as they were constantly occurring in New York and the adjacent towns, in which the Hudson River ice is used, we did not find, and we should not expect to find, any marked excess of typhoid fever from among those who habitually use ice for drinking purposes over those who do not. This was because the sanitary surroundings of the classes which use little ice were so much less favorable, as a rule, than those of the habitual ice consumers, that other sources of infection, equally, and even more efficient, would abundantly cover any difference in the number of cases in the two classes that might otherwise be noticeable. Whether infection through impure ice is of frequent or infrequent occurrence, was not now known. That it was not, however, so important a factor in the transmission of the disease as to render the typhoid fever statistics of New York worse than those of other towns, whose residents use cleaner ice, was certain. But there was a considerable number of cases of typhoid in which the most painstaking examination of the sanitary surroundings of the victims and their personal contacts failed entirely to account for the origin of the disease; and some of these might well be cases of ice-poisoning from the typhoid bacillus.

It was to be remembered in considering this, as all other bacterial diseases, that the bacteria themselves were only one factor in determining the disease. There was to be taken into the account also the number of the bacteria—that is, the size of the dose—and the conditions of predisposition or susceptibility of the individual. Unfortunately, however, we know nothing about the number of typhoid bacilli necessary to induce the disease in man, and we were nearly equally ignorant concerning the nature of the predisposing conditions. So, then, if we summed up what we really know about the relation of Hudson River ice to typhoid fever, we could only say that it is certain that the ice from some parts of the river must contain the bacteria of typhoid fever, and that these may be taken into the system in a living condition with ice-water. Whether the necessary relationship between the number of bacteria thus taken and the condition of predisposition of the individual occurred frequently, or ever occurred at all, we could not positively say; but the grave character of the disease should warn us against indifference and impress upon us the importance of adopting such measures as will secure the consumer against even the possibility of such infection.

With the bacteria of suppurative and pyæmia, the case seemed much less serious, because of the very general antiseptic treatment of wounds now in vogue; but the fact that the *staphylococcus pyogenes* might be in the Hudson River ice in a living condition should not be lost sight of.

Dr. Prudden next considered the practical measures which, as these studies seemed to show, should be adopted in order to guard against a not only possi-

ble, but very probable, source of danger in the Hudson River ice. He would not leave out of sight the great and important private and corporate interests which are involved in the supply and consumption of ice; nor would he wish in any measure to suggest by these studies a curtailment in the consumption of ice, even for drinking purposes. The measures which might be adopted in view of the present condition of affairs were of two kinds; first, such as would come under the supervision of health officers, and, second, those which belonged in the province of the individual consumer.

In the first place, then, it would seem necessary that the State Board of Health, or some other authorized body, should be placed in charge of the ice-harvesting fields, and, by a system of inspection not less strict than that which should exist in the case of the ordinary water-supply, determine which, if any of the sources of ice-supply are so situated as to imperil the health of consumers of ice. In view of Dr. Prudden's investigations, this would appear to be comparatively simple in all cases except that of the Hudson River. Here it would be necessary to establish by a most thorough scientific examination the distances from all sources of sewage pollution at which it might be safely assumed that the water had freed itself from the bacterial and other impurities sufficiently to form safe ice. It might in this way be possible to remove any chance of danger by permitting the questionable or bad ice to be sold only for cooling purposes, if such a classification were practicable, and thus not materially interfere with the interests of the ice companies. A compulsory system of disinfection of excreta in infectious diseases might be instituted, as it had been in other countries in which the purity of the water-supply was under constant supervision.

As regards the precautions which the individual consumer might adopt, it was evident, from the facts that had been brought forward, that if he could be certain that his supply came only from the lakes or ponds he would secure for himself a fair degree of immunity from danger. Remembering that the larger and more responsible ice companies did not, so far as he was aware, cut ice in the immediate vicinity of Albany, but at a considerable, and in most cases a great, distance below, the householder might eliminate to a large extent his hazard by finding out as accurately as possible just what part of the river his ice came from. Whatever the source of supply, however, the large excess of bacteria which in almost all cases the snow layer harbored, over transparent and sparsely bubbly ice, would render imperative the avoidance of snow-ice for any but cooling purposes. Still, it was not to be forgotten that perfectly clear ice might contain very large number of living bacteria.

A variety of devices could be adopted in the use of ice for cooling drinking-water so as to avoid placing it in the water itself; or recourse might be had to artificial ice made from pure water, which, as abundant experience had shown, could be furnished at a cost not greatly exceeding that at which the natural ice was furnished. This artificial freezing of pure water was already done in some of the European cities in which the natural ice contains large bacterial impurities.

In this series of pioneer studies on the bacterial impurities of ice, Dr. Prudden said he would rest content with having by experimental means endeavored

to give definiteness and precision, not only to the problem in general, but to the detailed questions which arise in connection with the ice-supply of one particular town. It would appear, he thought, that we now know with tolerable certainty just what series of questions are to be answered, and what investigations made, in order to decide upon the safety of any given source of ice-supply. But these detailed investigations could only be made under the sanction and direction of the public authorities. It was unfortunate that a certain amount of perhaps entirely unjust opprobrium was now attached to all the Hudson River ice, when it should perhaps belong only to that harvested in particular regions. It would seem, therefore, that it is greatly to the interest of the ice companies, as well as the public, that the State Health Authorities should take the matter of systematic examination of the Hudson River ice-fields at once in charge.

In conclusion, he said he wished to express his sincere hope that this study might not be looked upon in a sensational light, nor regarded as a polemic against ice companies or dealers, or against the free and wonted use of ice. A most thorough personal examination of the ice harvesting and the purpose and practice of the more responsible dealers led to no other conclusion than that they were as desirous as could be reasonably expected of them to furnish a clean product to the market; and so far as the current knowledge hitherto had gone, had apparently done so. But, in the clear light which the new methods of science throw upon the whole subject of important ice impurities, it seemed necessary that a sweeping reform in some respects should speedily be brought about. This long series of studies had been carried out in the hope that in the light of its results the rapidly-developing discipline of Preventive Medicine might find a plan of curtailment in some degree the number of annual victims to preventable disease.

### Recent Literature.

*A Manual of Diseases of the Nervous System.* By W. R. GOWERS, M.D., F.R.C.P. Volume I. Diseases of the Spinal Cord and Nerves. 8vo. pp. xv. 463. With 171 illustrations. Philadelphia: P. Blakiston, Son & Co. 1886.

The many readers of Dr. Gowers' two books on the brain and spinal cord have been looking forward with eagerness to his long promised work on diseases of the nervous system, and the volume before us will more than repay their expectations. The author's aim has been "to give an account of diseases of the nervous system sufficiently concise . . . yet adequate in its outline," and the result is decidedly a success.

The introductory chapter on classification, however, is not calculated to add to the author's reputation as a pathologist. Considering the ordinary classification into organic and functional diseases inadequate, the author adds two other classes—"structural," where the changes can be seen only or chiefly by the microscope, and "nutritional," where the changes are molecular and invisible. Sclerosis is given as the type of the former, and general paralysis, paralysis agitans, and chorea as types of the latter. Fortunately the

author does not obtrude this classification upon us in the rest of the book, so that it does but little harm.

General symptomatology is next discussed clearly and briefly, sections being given to disturbances of motion, sensation and nutrition, reflex action, and electrical phenomena. Under tendon-reflex, or "myotatic contraction," the author repeats his former statements that these contractions are not reflex, but that probably passive tension of a muscle "excites, by a reflex influence, a state of extreme irritability to local stimulation." A brief but clear account of electrical reactions is given here as an introduction to a full discussion of the subject in the section on diseases of the nerves. This introductory section is concluded by an admirable chapter on the action of the different muscles and the effects of paralysis of them, based largely on Duchenne's "*Physiologie des Mouvements*," and illustrated by a number of outline drawings. Such a chapter is a novelty, and taken in conjunction with the detailed accounts of the functions of the peripheral nerves and the different segments of the cord, which are given later, renders the diagnosis of any form of spinal or peripheral paralysis a comparatively simple matter.

The section on diseases of the nerves shows the enormous advance made in our knowledge of the subject in the last five years. It is certainly a surprise, for neuralgia and spasm are not touched upon, while sixty pages are devoted to the structural diseases of the nerves,—injury, neuritis, and neuroma. The pathology of nerve injury and neuritis is based almost exclusively upon the work of Ranvier and Pitrès and Vaillard, the work of Neumann, Mayor, and others, being neglected. The subject, however, is presented clearly and in sufficient detail for the student. Sciatica is, with much reason, given a place among the neuritides, rather than among the neuralgias. An excellent chapter on multiple neuritis in its various forms, including beri-beri and leprosy neuritis, concludes this section.

The third part is devoted to the diseases of the spinal cord, and occupies the remaining 350 pages of the book. The author's own investigations in regard to secondary degeneration enable him to speak from experience as to the anatomy of the cord, and the course of the different systems of fibres, but the work of others is by no means disregarded, and we have one of the fullest and clearest chapters on the anatomy of the cord to be found in any recent work. As an example of the admirable simplicity of some of his explanations for the student we would call attention to the diagram of an element of the motor tract on page 116, where we see the motor fibre, apart from the complexity and confusion of anatomical detail, set forth so plainly that the stupidest student can grasp the idea of it, and comprehend the localization of its diseases. The chapter on anatomy is followed by equally good chapters on the functions of the cord, and the general symptomatology of its diseases, and then the different diseases are considered in turn.

We must thank Dr. Gowers for having been the first, since Leyden, to devote a section to the diseases of the vertebral column, for, as he himself says, the work would be incomplete without "some mention of the morbid states that begin" in the spine itself. These morbid states, he thinks, give rise to symptoms due not simply to pressure upon the cord, but to a true myelitis set up by the neighboring morbid process. In the section on diseases of the meninges he still holds

to a belief in a primary chronic leptomeningitis. The diseases of the cord itself are divided broadly into two great classes—inflammatory processes and degenerative processes—the inflammatory character of tabes and progressive muscular atrophy being denied. With this latter disease are also considered, for convenience, pseudo-hypertrophic muscular paralysis and the various forms of myopathic atrophy. We have not space to dwell upon this portion of the work, but we must call attention to two important statements. Most of us, although admitting with Strümpell the pathological identity of progressive muscular atrophy and amyotrophic lateral sclerosis, have still held to a clinical and anatomical distinction between the two, but Dr. Gowers not only denies the definite clinical distinction, but holds to the anatomical identity of the two diseases. "I have not yet met," he says, "with a single case of progressive muscular atrophy in which the pyramidal tracts were unaffected, and I am not aware that any case of the kind has been published since attention was directed to the affections of these tracts by the researches of Charcot." His prognosis in tabes, too, is much more hopeful than that given by most writers. "It is not uniformly bad. Arrest is frequent, considerable improvement is not rare, but perfect recovery scarcely ever takes place." In his description of the various diseases he is always clear and well up with the latest researches, his articles on pathology are admirably complete, his symptomatology and diagnosis are excellent, and in treatment he is wisely sceptical. As an example of this we would refer to his remarks upon the value of electricity in infantile paralysis, on page 270.

A word must be said for the illustrations. The author has spared us the old friends that have done duty for twenty years or more, and given us a large selection drawn chiefly from his own cases. They all of them show admirably what the author wishes to call attention to, and the various sections of the nerves and cord look like the reality, although in some the process does not fully represent the character of the tissue.

We shall look for the second volume of this work with great interest, for, if it maintains the standard of this one, we shall have a work that may be considered the best treatise on diseases of the nervous system in the English language.

*Elements of Static Electricity.* By PHILIP ATKINSON, A.M., Ph.D. pp. 227. W. J. Johnston, publisher. 1887.

This elementary treatise on static or frictional electricity is very concise, and is clearly written. It has no practical application to medical treatment, but would prove of value to any medical practitioner who may desire to use this form of electricity in diseases in which it may be indicated. In our opinion these indications are but little understood and would probably be restricted to certain forms of hysteria, in which sudden electrical shocks might produce favorable moral effects.

The explanation of the physical causes and effects of lightning and thunder is very graphic, and well conceived.

—Dr. John S. Billings has been appointed Lecturer on the History of Medicine in Harvard University for the current year.

THE BOSTON  
Medical and Surgical Journal.

THURSDAY, APRIL 7, 1887.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

**SUBSCRIPTION TERMS:** \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 203 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 203 Washington Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES, UPHAM & COMPANY,  
203 WASHINGTON STREET, BOSTON, MASS.

THE MOVEMENT TOWARDS PHYSICAL  
CULTURE.

We cannot allow the opportunity to pass, which is presented by the lecture of Professor Hartwell, to be found in this and the preceding number of the JOURNAL, without again calling the attention of our readers to the importance of the subject of physical training, especially as a constituent part of every properly-designed educational system. Professor Hartwell's lecture brings out with especial emphasis one most important point, namely, the relation between muscular exercise and central nervous activity. It has been much the custom to speak of physical exercise as a useful addendum or supplement to mental training, but it is time educators were shown, what they can best learn through the medical profession, namely, that muscle-training is brain-culture. The phenomena accompanying a given muscular act are not confined to the renewal of tissue in the muscle contracted, but include, as well, the original motor impulse of the central nervous organ, the action of the coördinating centre, and the transmission of the impulse through the nervous trunks to the motorial end-plates, as well as the afferent impulse to the centre of the muscular sense, conveying information of the work that has been done.

A training merely by books, a training simply through eye and ear, must leave such parts of the brain undeveloped as are connected with the motor and sensory centres of the great muscular systems of the body. The manual training schools which have come into vogue of late years are thus seen to be something more than mere utilitarian schemes. They give an actual mental education. The old-fashioned apprenticeships, with their seven years of precise manual training, were, perhaps, after all, not so immeasurably inferior as educational methods, in the broad sense of the term, to the common school system of the present day.

The present methods of teaching chemistry and physics recognize the hand as a most important channel through which to reach the brain, for the best teachers

are aware that it is not through seeing certain experiments performed, least of all, through reading of them in a text-book, that the pupil gets the most good. The personal use of instruments of precision involving, primarily, the tactile sense, is worth more as an educational agency than a fluent repetition of all the laws of physics.

Handcraft is a good path to rede-craft. Indeed, the very history of the words *craft* and *cunning*, before they acquired their modern sinister meaning, shows that muscular skill and strength led to mental power. As some one, we believe Carlyle, has said, the cunning man is the *canning* man — the man that *can*, the true *könig*, or king of men.

Though we have not the pleasure of noting, as yet, any serious and general attempt to incorporate physical training into our public school system, there are not wanting tokens that the public mind is awaking to the importance of the subject, and that a sentiment is forming, which will, sooner or later, make itself felt on boards of public education. A movement begun in Boston, this spring, towards the formation of an athletic club, has met with a most enthusiastic reception. Before a situation has been even decided upon for a building, the limit of membership is already full, a thousand names having been enrolled.

The alumni of Amherst College recently held a meeting in New York, at which it was decided to establish a professorship of physical culture in that college, in memory of Henry Ward Beecher. The endowment of \$50,000 is now, we understand, in process of being raised for that purpose.

During the past winter, a gymnasium for women has been opened in Boston, which is probably superior to anything of the kind in the United States. The gymnasium has existed here for nine years, but has been hitherto cramped by insufficient facilities, until its friends erected the present commodious structure, where about 350 women and children are now regularly instructed in the best methods of physical culture.

A hall 96 x 63 feet, and 34 feet high, well lighted and ventilated, is furnished with all the requirements for light, and many for heavier gymnastics; while fifty-two dressing-rooms, each with a bowl set above an asphalt floor, give the opportunity so important for sponging and rubbing after the exercise. To see a class of fifty women, in easy-fitting gymnastic habit, going through the dumb-bell and chest-weight drill, to musical accompaniment, and ending, perchance, with a few laps on the patent running track, is a sight that once would have been a surprise. But this work is going on steadily and quietly, and with results which are already apparent to the friends and physicians of some of the pupils, and whose good effects are to be confidently looked for in the coming generation of children.

A particularly interesting feature of this work is the establishment of a normal class for the training of teachers of gymnastics for women and children. That there is to be a call for such teachers seems very evi-

dent, and the work opens a new field for female labor, which, in the present overcrowded state of many other callings for self-supporting women, will probably attract those whose tastes lie in this direction. The importance of skilled supervision of all persons, male, and perhaps we may add, especially female, who undertake to work in regularly-equipped gymnasia, is sufficiently obvious. But it is also desirable that such instruction may be given to women, especially those who are already teachers of other branches in the schools, so that they may be able to teach *con amore*, "hall gymnastics" so soon as the time is ripe for the introduction of such exercises into the public schools. In Germany, a normal course in physical culture is required of school-teachers, as a prerequisite to receiving their commissions, and it is only as taught by the regular teachers that a system of physical exercise can ever be successful in the schools.

A collateral fact which almost escaped our attention but which illustrates one phase of the athletic *renaissance*, is the growing favor of "slugging" both as a profession, and a means of elegant spectacular recreation among the favored sons of fortune. A recent bloody and highly successful "mill" in the neighborhood of Boston was, if the uninvited but ubiquitous newspaper reporter is to be believed, largely officered by men not unknown to the most esoteric circles of the social, professional, and (shall we add?) the literary world. While the recent death of a city father who won his early triumphs in the prize-ring and who did not disdain to put on the gloves for money and fame, even after he had attained the acme of his municipal aggrandizement, seems to remind us of our likeness to ancient Greece, when to win in the Olympic games was the shortest road to the highest civic honors. It is indeed to the wearer of the *cæstus* that such preferment is now chiefly reserved, and the hero after receiving the homage of his countrymen during life, has a mighty funeral while the "championship belt" in choicest exotics is laid upon his bier.

#### IS ALL MATTER ENDOWED WITH A SENSE OF FEELING?

PROF. PREYER, of Jena, has published in the *Deutsche Rundschau*, an article, reproduced in the *Popular Science Monthly*, which restates the view, advocated by Heckel, and by Lewes, that there is no hard and fast line between the sentience of the higher animals, and the *sensitiveness* which inorganic substances (for example, the photographer's plate) and plants manifest. "It is," he says, "in accordance with facts to assume that there is no well-developed dividing line between beings capable and things incapable of feeling, but that all matter is endowed with a certain *sense of feeling*, which, however, only with a definite and an extremely complex arrangement and vibration of the molecules, will develop into *feeling*."

"The simple bodies, the dead elements, therefore, although for the most part very easily changed through slight influences, are, in spite of their dim sense of feeling, not able to feel perceptibly (*sic*), but as soon as they become part of the ganglionic cell of the brain, or only of the living protoplasm (through assimilation of food), they, combined with others, will by indescribably complex vibrations, cause feeling to arise whenever an impression is made on them."

"Every physiological expression must, above all, be in perfect accord with morphological, mechanical and chemical facts; on that all physiologists lay the greatest stress, but I do not understand why, regardless of physiological facts, morphologists, physicists, and chemists should be allowed to declare their explanations and principles to be the only true ones, or even the only possible ones. It has been demonstrated that matter must have other fundamental properties besides those ascribed to it by physicists and chemists. The axiom of mechanics, 'Matter is dead!' will soon become obsolete, since a sense of feeling is inherent in all matter. . . . No one can hear a single leaflet tremble in the wind, but during a storm the roaring of the forest caused by many leaves rustling together may reach awe-inspiring power. Similarly, each molecule of matter may feel imperceptibly little, when vibrating by itself, while, together with many particles feeling likewise imperceptibly, it may coöperate in manifesting feeling, which, like lightning, arises and vanishes."

"Through this conception, through acknowledging evolution and the sense of feeling, the whole of Nature may be brought into harmonious connection."

The above citations seem to us only another desperate and not very successful attempt to construct the psychological out of the physiological and material. With all due respect to Prof. Preyer, we are unable to understand what it is to have a "sense of feeling" without being able to "feel" or what it is to "feel imperceptibly." We cannot, however, forbear sympathizing with every effort to bring "the whole of Nature into harmonious connection."

#### FLUID EXTRACTS vs. TINCTURES.

DR. H. S. LOTT in the *Atlanta Medical Journal* has called attention to the relative superiority of fluid extracts over tinctures. As defined in the "United States Pharmacopæia," "fluid extracts are permanent concentrated solutions of vegetable drugs, made of such strength that one fluid ounce contains the medicinal principles and represents the virtues of one troy ounce of the drug." One minim of the fluid extract is believed to be equal in strength and virtue to one grain of the drug, while being at the same time freed in great measure from the inert principles of the crude drug. It cannot be said that tinctures are so convenient of administration, or so well represent the active properties of the drug.

"Tinctures," the writer says, "are alcoholic solutions of medicinal substances as such, and by virtue of the necessarily various processes by which they are obtained, they cannot be made of uniform strength—uniform in the sense which we, as prescribing physicians, would have them. For instance, one tincture will represent twenty per cent. by weight of the strength of the drug, and another will only represent five per cent. And why must it be the case? Because the nature of the plants has willed it so. One plant holds its active medicinal principles in a readily soluble state. As soon as the alcoholic or ethereal menstruum is poured upon the powdered drug, it yields up its active virtues and only a residuum of inert substance is left, while another plant contains a much smaller per cent. of the active principles, or becomes exhausted by the menstruum less readily. Thus you see how utterly impossible it is for us to have, in accordance with the justly fixed laws of the pharmacopœia, our tinctures of a uniform strength, representing relatively minim for grain; whereas, the same facts which militate against the use of tinctures recommend fluid extracts as possessing advantages which are beyond question, and the nature of these facts is such that their truth will be at once recognized by all intelligent and practical observers.

"In the manufacture of fluid extracts—and in this I have the high authority of Parke, Davis & Co., and E. R. Squibb—the relative connection between the drug and the menstruum is considered well, and demonstrated by experiment, before the process of exhaustion is begun. Such menstruum is selected as will most thoroughly exhaust the drug of its active medicinal principles, and having obtained these, free from inert and deleterious substances, will preserve them in a pure and healthy state for an indefinite space of time."

Dr. Lott claims that fluid extracts, while just as easily administered as tinctures (a smaller dose only being required), may be rendered quite as palatable by giving them in glycerine and water as a menstruum; moreover, they are more reliable. He refers to the case of ergot of rye, and asks: "What physician of the present day who has kept pace with his profession, would think of administering the tincture of ergot as oxytotic, or to relative congestion of the spinal cord, or pulmonary hæmorrhage, when long experience and observation have proven so conclusively the superior value of the fluid extract, that the tincture has become almost entirely obsolete?"

#### MEDICAL NOTES.

—The *Medical and Surgical Reporter* quotes Professor Bartholow as saying "that the popular poison, 'Rough on Rats,' owes its efficacy to phosphorus. Being an oily or fatty preparation, when taken into the stomach, its action as a poison is very rapid." The truth of the statement contained in the last clause, will be generally admitted, but either our contemporary or its alleged authority is at fault in ascribing the deadly effects of the poison to phosphorus. The lethal ingredient is white arsenic.

—Dr. York, of "Druidic" fame, having found the atmosphere of Maine too chilling for him by reason of the harsh attitude of the law, is said to be about to join the great army of the oppressed, who come to the welcoming arms of Massachusetts. The *Leviathan Gazette* sends after him this feeling farewell and *viaticum*:

So Dr. York will lie him to the greenhorns and patients new of Boston town. Dr. York evidently acts on the principle recorded in the diary of the once famous Tichborne claimant: "Some has money and some has brains; them that has money

was made for them that has brains." This reads just like a Druidic gem of thought and we present it to the chief bard of all the Gorsedhs with our parting blessing. Go forth, thou prince of quacks, thou inimitable nineteenth-century Cagliostro and bardic wonder, go forth doctoring and to doctor, electrifying and to electrify. Physic the fools to the top of their bent. Light up the darkness of Boston and the Massachusetts wilderness with the gospel according to St. Moran, and may thy trusty sword of Bunker Hill flash like a flaming meteor before the dazzled eyes of newspaper reporters and all the imps of darkness who would harm thee, sending them panic stricken to their lairs. Go, noble Gorsedh; go. Stay not upon the order of thy going, but go at once, and may the Druidic University of noble Gorsedhs of Maine go with thee.

—Small-pox is reported as quite active in Mexico, and cholera exists in Catania, Sicily, and Pesth, Austria.

—The annual commencement of the Medico-Chirurgical College of Philadelphia takes place at Association Hall, in that city, Thursday evening, April 7, 1887, at eight o'clock.

—Mrs. Mary Manning died in Wakefield, Mass., March 27th, aged 105 years. She was born in Dublin, Ire., in 1782, and came to this country about thirty years ago, and has lived in that town for the past twenty years. She retained her eyesight and hearing to a remarkable degree, but had been childless for a few years past.

—Two prominent physicians of Cincinnati, one of whom, Dr. R. B. Davy, is the president of the Cincinnati Medical Society, have purchased a piece of property known as Marilou Park, containing one hundred and twenty-nine acres of land, in the suburbs of San Diego, California. It is to be fitted up as a sanitarium for the benefit of invalids not able to profit under ordinary hotel life. In addition to a mansion house, there are to be a number of separate villas to contain from two to six rooms each, scattered about the park.

—The Governor of Maine has vetoed a bill recently passed by the Legislature of that State, entitled, "An Act to Regulate the Practice of Medicine," one of the provisions of which required the registration of practitioners of medicine. The grounds of the veto we have not yet seen stated; it was, in fact, supposed for a time that the bill had become law.

—The work of the General Medical Council, of England, seems to be measurable by linear measure rather than weight. It was stated by Dr. Quain, chairman of the Finance Committee, that, taken altogether, the expense of the Council averages £1 per minute. Even this statement did not have the desired effect of checking the irrelevant loquacity of sundry members, whose aim in life would seem to be to raise and prolong a futile discussion on points of order or disorder. The more the talk the larger the fees.

—The *Philadelphia Medical Times* says that a prominent surgeon of that city lost a good patient, a spinster, the very pattern of propriety, by writing a prescription for "Fluid Ext. Rham. Cat." After reading the prescription, she said nothing could induce her to swallow such a remedy, and that the doctor ought to be ashamed of himself for ordering it. He

is now a sadder and a wiser man, and keeps on the safe side by prescribing castor oil for his hysterical patients.

— It will be remembered that, some months ago, a party of excursionists went on a steamer from Glasgow to witness the effect of certain large blasting operations, which were to take place on Loch Fyne. In the blast, six and one-half tons of gunpowder were exploded; and after it was over, the excursionists went on shore to look at the effect of the shock. In a short time many of them were seized with faintness; six of them died almost immediately, one died shortly after, and five were made very sick, but eventually recovered. The results of the scientific interest which followed this sad affair have been published, and have brought out the fact that the mischief was probably due to carbonic oxide, of which it was calculated 468 pounds could be generated by an explosion of the quantity of gunpowder named above, an amount which, at the ordinary temperature and pressure, would occupy a space of 6,333 cubic feet. This would be sufficient to vitiate one hundred times as many cubic feet of air. But, in the presence of carbonic anhydride, of which the explosion would generate 3,575 pounds, it would render 1,266,000 cubic feet of air fatal to human life. The symptoms of those who suffered or died agreed with those attributed to poisoning by carbonic anhydride, and it is said that the blood of one of the deceased was so liquified after death that it flowed through the coffin.

#### BOSTON.

— At the banquet given to Mr. Theodore Metcalf by the Boston Druggists Association, mention of which was made in our last issue, Dr. Oliver Wendell Holmes made the following remarks, in responding for the medical profession, which were received with much enthusiasm, and will meet with appreciation from our readers notwithstanding the *quasi* endorsement of prescribing across the counter:

I consider it a very great privilege, gentlemen, to be allowed to take part in this tribute to my old friend and my old neighbor; for none of you, perhaps, but he and I and one or two others, may possibly recollect the time when he and I were neighbors. I hung out my modest sign under the room almost directly over his shop; and there I was ready to receive the smallest favors as he was the smallest favors. [Great laughter and applause.] There never was a more convenient and happy arrangement than that which brought us together. I wrote my prescriptions up-stairs; the patient went down, and it was filled out down-stairs. We could not always be fortunate. We deserved success, but we could not always command it. The excellent Martin Smith, the revered sexton of the churchyard opposite, was always at hand to finish the work upon which we had entered.

In thinking what I could say which would interest this assembly, I thought a few recollections of some of the older apothecaries might be agreeable to you, as they come up before me in fragrant succession by the drugs which filled their old-fashioned and not over-erated establishments. I will mention their names one after the other. Ephraim Elliot, if I recollect, was one of the oldest—a little gentleman, active, attending himself to everything, conscientious and scrupulous. I have seriously doubted whether he ever killed a patient, except with a prescription behind him to back him, in the course of his long and estimable life.

Charles White rises before me—tall, swarthy, soft-spoken, with a long, somewhat elongated son, who may be here now, perhaps. I cannot say whether he is among the living or not. I remember that my good friend, Dr. Hooper, spoke of him as "carrying his father's 'liniments' in his countenance." [Loud laughter and applause.]

Thomas Farrington is in my mind, an easy recollection, as creeping about under the Tremont House. Of him I remember comparatively little except that he had the air of a man that was getting every year more and more venerable and thinking harder and harder, in the duties he had to perform.

Daniel Henchman, the Methuselah of Cambridge Street, who I thought must have been embalmed while living, so did he outlast all of his contemporaries.

Joseph T. Brown [applause], who was once my landlord. [Laughter.] In a professional capacity, I had rooms over him, and I will say of him before this assembly that he was the best and kindest landlord that ever breathed [applause], and I was the worst and most intolerable tenant that ever occupied a chamber. How he endured me in the pursuit of my honest vocation, which was one not flattering to my enterprise, I never could imagine. His name is Brown, but it should have been Green, for his spring is eternal. [Laughter and applause.]

This, I believe, closes the list of those old, ancient apothecaries. And now I wish to say one thing more, which, if any member of my own profession is here—and there are several—I hope he will pardon me for saying. I have always had a great opinion of the medical advice of apothecaries. [Laughter and applause.] The truth is, they put up the prescriptions of all the best physicians in the place in which they live, and they have the very cream of all their wisdom at their fingers' ends. So, when I have myself been suffering from any slight bodily inconvenience, I am ashamed to say—or ought to be, perhaps—instead of going to a professional brother, I have quietly crept into the back-room and asked Mr. Metcalf what such and such a doctor was in the habit of prescribing. [Great laughter and applause.] And therefore, having made this confession, in order to place myself, in a certain sense, right with my brother, I shall only say that it will give me great pleasure to join you in drinking the health of my Doctor Metcalf. [Loud and long continued applause.]

— On a death-certificate lately received by the Board of Health, the cause of death given by the physician signing it was: "Over-study induced by the Boston public schools' system of cramming."

— Another death from "Rough on Rats" occurred at the City Hospital last week, a man having taken four-fifths of a box of that commodity, and dying twenty-four hours afterwards from acute arsenical poisoning.

#### NEW YORK.

— Dr. Wm. T. Lusk successfully performed the Cæsarean section at Bellevue Hospital on the 23d of March; saving both the mother and child.

— Dr. D. B. St. John Roosa presided at the annual dinner of the New York Post-Graduate Medical School and Hospital, which was held at the Hotel Brunswick on the evening of April 4th, and among the speakers were Gen. Wm. T. Sherman and Dr. Wm. A. Hammond.

— The graduating exercises of the New York Hospital Training School for Nurses took place at the hospital March 31st, when diplomas were given to nine graduates. Miss Bird delivered the valedictory address, in the course of which she spoke of the various ideas of a nurse presented by Evangeline, Lucille, and Sarah Gamp.

— It is said that a large number of young calves, from one hour to three days old, are being slaughtered

in Herkimer and Oneida counties and sent to New York, where they are put up as "canned chicken." Many tons of this "bob-veal" have already been seized and condemned this season by the sanitary authorities; but doubtless a considerable amount is brought into the city which escapes their notice.

— The limited express train which arrived from Boston on the night of March 30th, is said to have been the first train ever run in this country without a possible source of fire in every car. The Martin steam-heating apparatus, which is now being tested on the New York Central and Hudson River Railroad, stood the trial successfully for the two hundred and forty mile run, and by means of the Julian storage system the cars were well lighted by electricity, both inside and on the platform.

— The Kings County Medical Association which has recently been organized in affiliation with the New York State and American Medical Associations held its first stated meeting at Remson Hall, Brooklyn, on Tuesday evening, April 5th. The subject considered was Oil of Wintergreen as a Therapeutic Agent, and the discussion was opened by a paper from Dr. E. R. Squibb. In accordance with a provision of the by-laws the monthly meetings are to be adjourned by limitation at 10 o'clock for refreshments and social intercourse.

### Miscellany.

#### ANTIFEBRIN.

The *Therapeutic Gazette* quotes from the *Deutsche Medizinische Zeitung* of December 23, 1887, the conclusions of Eisenhart regarding antifebrin, which he has used in Ziemssen's clinic in Munich: The number of cases observed was thirty. The doses given were from four to eight grains, given in powder and solution, by rectal and anal use. In a case of erysipelas a dose of eight grains was vomited when given by the mouth; when given by injection it was retained.

In general, the drug was well borne; half of the patients had a profuse perspiration following, and an exanthem occurred in one case.

Cases of typhoid, treated with antifebrin, had an easy course. The influence of the drug was generally manifested two hours after it had been taken. After a dose of four grains the temperature sank six times from one-tenth to one degree, thirteen times from one to two degrees, fifteen times from two to three degrees, six times from three to four degrees, and three times more than four degrees. After a dose of eight grains a depression of temperature of one-tenth to one degree occurred three times; from two to three degrees, seven times; from three to four degrees, twice; from three to more than four degrees, twice. In a few cases only was this effect wanting.

In comparison with antipyrin it was found that one-fourth as much antifebrin as antipyrin was required for a given effect. The conclusions of the observer were, that in doses of four to eight grains antifebrin was a very valuable febrifuge, reasonably certain of success.

#### NINE HOURS OF ARTIFICIAL RESPIRATION.

THE *Medical Press and Circular* publishes reports from Ceylon containing an interesting description of recovery of consciousness of the taxidermist of the Victoria Museum who was bitten by a cobra, which he thought harmless, from previous extraction of the poison bag. For a few moments after the bite he took no heed of it, but pain and nausea were soon set up. Carbolic acid was then applied, ligatures were bound round the arm, an incision was made at the bite, and the blood of the arm was wholly removed. Various antidotes were used, but the unfortunate man lost the power of speech, and soon every muscle became paralyzed, and respiration ceased. Artificial respiration was then resorted to, and this operation was unceasingly continued for nine hours, when at last the patient made an attempt to breathe, and soon regained consciousness enough to make his wants known. He steadily improved until Friday, the accident having taken place on Wednesday, and then astonished those around him by stating he was conscious of all that had been taking place, but was unable to make his feelings known, not having the power over a single muscle. It would seem that the poison paralyzed the nerves of motion, but not those of feeling, for he could see and hear and feel, although the attending physician, even by touching the eyeball, could get no response either of feeling or consciousness. His partial recovery was, however, followed by a high fever and inflammation of the lungs, and he died, perfectly conscious, on the following Sunday.

#### ON THE MEDICATION OF NERVES.

DR. LEONARD CORNING (*New York Medical Monthly*), has brought to the notice of the profession a new method of treating neuralgias and other derangements of the peripheral nervous system. It consists in copious deep injections over the affected nerve of a four per cent. solution of hydrochlorate of cocaine, incarcerating the medicament by the application of a tourniquet above the point of injection. "In sciatica the tourniquet should be placed as high up as possible, so as to interrupt the circulation in the crural artery above the point of injection." In the first case reported by Dr. Corning, after the removal of the tourniquet there was no return of pain for four days; the treatment was again resorted to; the periods of exemption became longer and longer until the pain finally left the patient for good. Two other cases of obstinate sciatica have yielded to the same medication. Dr. Corning's conclusions are as follows:

"(1) That this method of subjecting the nerve to the prolonged chemical action of an adjacent medicament possesses advantages of a theoretical and practical nature which are not easily overestimated.

"(2) That this prolonged medication of the nerve, by incarceration of the medicament, is incomparably more advantageous than the ancient expedient of simple injection, without incarceration by suspension of the circulation. In the former case the medicament is held in contact with the nerve for a period of time, which may be prolonged at the discretion of the physician. In the latter case it is a matter of extreme doubt whether the nerve is influenced to any appreciable extent, since the medicinal solution is at once removed by the general circulation, and has, therefore, no time to induce the requisite chemical changes in the nerve filaments.

"(3) Solutions of low percentage (one-half per cent. or one-fourth per cent.) should be employed for prolonged medication of nerves, as it is thus possible to inject large quantities of the medicament without danger of constitutional symptoms. It is, moreover, clear that the prolonged presence of this large amount of fluid in the neighborhood of the nerve-stem must inevitably,

through the operation of imbibition, profoundly affect the nervous filaments.

"(4) The medicated fluid should be injected as near the affected nerve as possible; but care should be exercised not to wound the latter. These profound injections may be accomplished without pain by injecting a small quantity of the anæsthetic before the point of the needle, as the latter is propelled into the tissues.

"(5) The treatment by prolonged medication is without danger, and therefore superior to nerve-stretching by the surgical method, which in point of reliability leaves much to be desired.

"(6) Cocaine is only one of many fluids which may prove useful when applied according to this method.

"These, then, are some of the conclusions which have forced themselves upon me, and I confidently trust that the method of treatment above detailed may continue to yield rich results in the hands of my colleagues in the profession."

Since the publication of this article, Dr. Corning has experimented farther with this method, improving his appliances for the production of prolonged local anæsthesia; the results are recorded in the *Medical Record*, March 19, 1887.

### Correspondence.

#### GAS AND KEROSENE STOVES.

BOSTON, April 1, 1887.

MR. EDITOR.—The only answer to Dr. Lincoln<sup>1</sup> is: have a tunnel to your gas or kerosene stove leading to a chimney or out to the open air, to carry off the vapor or gaseous products of combustion, as in the case of any other stove or fireplace.

Yours truly,

EXPERTUS.

#### EXTRACTS FROM LETTERS FROM DR. WILLARD PARKER, OF NEW YORK, TO DR. EDWARD JARVIS, OF DORCHESTER, 1828-1881.

THE following extracts are taken from three letters written by the late Dr. Willard Parker, of New York, to the late Dr. Edward Jarvis, of Dorchester. The first two letters were written in 1828, when Dr. Parker was assistant at the Chelsea Marine Hospital, and the last letter fifty-one years later, from New York. The correspondence between these friends and classmates was kept up through all these years, and these letters were selected by Dr. James R. Chadwick from a large number given by Dr. Jarvis to the Boston Medical Library Association:

CHELSEA HOSPITAL, May 18, 1828.

I go to the General Hospital about once a week to witness operations. I visit the Eye and Ear Infirmary two or three times a week. A boat passes from near the door of the hospital for Boston every hour in the day, hence I have things as I would. You wished me to give you the course of my reading. I will mention the books in order: "Wistar on the Bones," "Cheselden on Bones and Muscles," "Richerand's Physiology," "Haller's Physiology," "Bigelow's Sequel," "Thacher's Dispensatory," "Thomas' Practice," "United States Pharmacopœia," "Dorsey's Surgery," 2 vols., "Benj. Bell's Treatise on Strictures," "Bell on Gonorrhœa and Lues Venerea," "Bell on the Muscles," while dissecting; "Hamilton's Midwifery," "Underwood on Diseases of Children," and am now reading, "Hunter on the Blood, Inflammation, etc.," and "Boyer's Works" in French. I take the Philadelphia journals and that affords me much matter for reading and thought. I read Good, as cases occur. I am certain I derive but little advantage from reading unless I see the practical utility of it. So, too, in reading of the muscles, without dissection, it does no good. I intend purchasing "Bichat" in French, if I can find it. I have read Abernethy's books and value them much in regard to regimen. I intend reading upon the eyes and ears now while I go to the infirmary. You

mention my situation for Russell; I shall retain it until I can find one that will afford me greater advantages in regard to my profession. (How I shall manage during the lectures I have not yet determined). I will have all the advantages for improvement in my profession this country affords. I can furnish myself with means. Dr. Dalton and others advise me by all means to stop here yet, as I cannot better myself, since I have the advantages of *Boston institutions*. My situation was bargained away last fall to your doctor's cousin; he is to graduate in August, at Brunswick, he will then enter his name with Dr. Townsend, and study to fit himself to succeed me. If Russell is determined to acquire a thorough knowledge of the profession, and not mind trifles he might, I think, obtain a good situation here; he would have six or eight hours in a day to study, board, and some pay. But I should not like a classmate in the situation while I remain; but the situation is one, that I should certainly be willing to take for a while, as all its duties belong to the profession.

Your chance is good for reading, but reading without practice you will find to be the shadow and not the reality. I hope to see you in Boston in June, when the good man, Dr. Shattuck, reads his dissertation. Why does not Russell study divinity? The call for ministry is great, and the expenses at commencement are very small, I hear. I should advise him to that unless he actually will love medicine as a profession. I would most cheerfully do all in my power to promote his interest, if he determines on medicine; if I can help him here I will. But I shall not relinquish my situation until about the last six months of my pupillage, unless I can find a better; I would exchange it now for none I know of. I think I shall stop a while with Dr. Shattuck when I leave here; if I do not I shall go into one of the dispensaries, or with Dr. Warren if I can.

WILLARD PARKER.

CHELSEA, July 10, 1828.

There has been nothing lately at the General Hospital. At this hospital there are about thirty patients, none very sick; have had no death; since you were here, there have been several very interesting cases; last week the doctor performed here Physic's operation for producing union between the fractured parts of one of the bones of the arm; it was the radius. The accident happened about three months since at sea, and the man, when he came into the house, had a *false joint*. Jackson,<sup>2</sup> Gould<sup>2</sup> and myself dispatched *id corpus quod vidisti*. Jackson is a very excellent anatomist; he gave us much information. I expect he is decidedly first in the Boston School, or Harvard University. You wished for my advice in regard to your accompanying Dr. Lincoln this winter, or rather fall, to Burlington. I should think the opportunity of being with him in the dissecting room and preparing his subjects for demonstration, would be one well worth embracing. I mentioned the matter to Dr. Townsend, he thought you would do well to accompany Dr. Lincoln, and then made some remarks on the importance of anatomical dissections, as if to give me a gentle hint not to spare the knife. His remarks seemed to say it was downright *quackery* in a man to pretend to understand *pathology* and to *prescribe*, if he was not acquainted with the mechanism of the parts constituting the human frame. I saw Dyer since I received your letter, asked his opinion in regard to your going to Burlington, he thought with me.

Bartlett, of Plymouth, is coming to Shattuck's in the fall. I would enter my name, if I were you, before him, and then you will be entitled to all the privileges of priority, which sometimes are not small. If I were situated as you are I should certainly go to Burlington, if I could be certain that I should have an opportunity to ply the knife; for myself, I find it folly to read alone and neglect all other things. If we have the principles of our profession well grounded in the mind, and are *practically* acquainted with anatomy, we shall find but little difficulty in the practice of medicine, I believe. Suppose a man to read two

<sup>1</sup> Dr. J. B. S. Jackson.

<sup>2</sup> Dr. A. A. Gould.

<sup>1</sup> See last number of Journal, page 319.

or three years on a complicated piece of machinery, and at the end of this time, the piece should be brought to him for repairing, would he, never having seen anything of the kind before, be competent to the task? I know I should not, for I have made the experiment. About three weeks ago a case of midwifery fell into my hands to my great joy, the woman was young, seventeen, her labor was tedious, it being her first child. I thought I should feel myself quite at home in the affray (having recently read a work upon that branch of our profession) but upon making examination to ascertain the presentation, instead of finding things distinct, as I had fancied in reading, I could think of nothing to which to liken the sensation produced to the hand, but that perceived on thrusting it into a mass of *soft soap*: this may seem ridiculous, but it is true. I believe we shall never regret the time spent in the dissecting room, if it be one-half of our pupilage.

The divinity students will now have a fine time, while we poor fellows must continue to dig, but if it be true, "that every dog has his day and every bitch her afternoon," we need not shut out from ourselves all hope of leisure to devote to ourselves and *ours*. Hosmer<sup>1</sup> will preach here at the commencement of next term, if nothing happens; will you attend, if in Boston? Write every opportunity or when you have a leisure moment to spare me. I remain your friend, WILLARD PARKER.

NEW YORK, March 13, 1881.

I was very glad to hear from you through your letter, and to know you are comfortable. I had not heard of the accident you met with; you say you were thrown from the top of a carriage; pray, what were you doing in that posi-

<sup>1</sup> Rev. Dr. Hosmer, of Watertown, a classmate.

tion? the good book, you know, says, persons like us are afraid of that which is high and fears should be in the way. I am sorry Hosmer<sup>2</sup> is among the suffering ones. He paralyzed the bladder by retaining the urine too long a time. When old, we must obey the call of nature. His trouble is cystitis chronic, kidneys are sound, the reaction is acid, although feebly. He should neglect no means of recovery. The triple phosphates show the urine meets with pus in the bladder; the urine is decomposed by it, and the irritation is kept up. The specific gravity is right, or nearly so.

Now in order that our dear old classmate recover, he must eat *little strong meat*, and make less urea; the nearer his urine approaches *pure spring water* the better. Bread-stuffs, milk, mild fruits, you tell him what to do. The bladder should be washed out at bedtime, with warm soft water and have the organ completely emptied; washing out in this way he will go without much disturbance during the night and gain strength. If he do not recover, some slight medication of the wash may aid: an infusion of *buchu*, and in the twenty-four hours or every twelve hours a couple of the capsules of capsaia may be employed. I have found the greatest relief from washing out the pus and triple phosphates.

When you write to Hosmer please assure him of my profound sympathy; we are all admonished that the *Conscious Ego*, the individual which says my hand, eye, or body, is making preparations to leave this tenement as the landlord is slow to make repairs.<sup>3</sup>

WILLARD PARKER.

<sup>2</sup> Referred to, in the second letter.

<sup>3</sup> A similar quaint expression is associated with the late Dr. Shattuck, from whom Dr. Parker had probably heard it fifty years before.

#### REPORTED MORTALITY FOR THE WEEK ENDING MARCH 26, 1887.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Northampton . . . . .	12,806	—	0	—	—	—	—	—

Deaths reported 1,812: under five years of age 638; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fevers) 231, acute lung diseases 303, consumption 262, diphtheria and croup 86, measles 43, diarrheal diseases 21, typhoid fever 17, scarlet fever 16, cerebro-spinal meningitis 15, whooping-cough 10, malarial fevers nine, puerperal fever five, erysipelas six, small-pox (New York) four. From typhoid fever, New York five, Boston and Milwaukee, two each, Baltimore, District of Columbia, Pittsburgh, Providence, Lowell and Somerville one each. From scarlet fever, New York 10, Baltimore three, Providence, Fall River and Somerville one each. From whooping-cough, New York, District of Columbia and Holyoke two each, Boston, Baltimore, Pittsburgh and Lynn one each. From malarial fever, New Orleans four, New York three, District of Columbia and Charleston one each. From erysipelas, New York five, Providence one. From cerebro-spinal meningitis, New York seven, Fall River two, Pittsburgh, Providence, Worcester, Haverhill, and Northampton one each. From puerperal fever, Milwaukee two, New York, Richmond and Charleston one each.

In the 23 cities and greater towns of Massachusetts, with a population of 1,083,162 (population of the State 1,941,465) the total death-rate for the week was 23.72 against 22.68 and 20.27 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,245,099, for the week ending March 12th, the death-rate was 21.6. Deaths reported 3,836; infants under one year of age 854; acute diseases of the respiratory organs (London) 423; measles 195, whooping-cough 83, scarlet fever 44, diarrhoea 32, diphtheria 31, fever 27.

The death-rates ranged from 16.1 in Derby to 37.1 in Manchester; Birmingham 18.5; Bradford 19.8; Brighton 21.2; Halifax 23.1; Hull 21.5; Leeds 17.2; Liverpool 25.9; London 20.4; Newcastle-on-Tyne 24.9; Nottingham 18.4; Sheffield 18.8; Sunderland 26.6.

In Edinburgh 19.0; Glasgow 29.5; Dublin 31.3.

The meteorological record for the week ending March 26, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.	
	Daily Mean.	Daily Mean.	Maximum.	Minimum.	7.00 A. M.	3.00 P. M.	11.00 P. M.	7.00 A. M.	3.00 P. M.	11.00 P. M.	7.00 A. M.	3.00 P. M.	11.00 P. M.	7.00 A. M.	3.00 P. M.	11.00 P. M.	Trajectory, Hrs. & Min.	Amount in Inches.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 26, 1887, TO APRIL 1, 1887.

PERLEY, HARRY O., captain and assistant Surgeon. Ordered for temporary duty at Fort Maginnis, M. T. S. O. 23, Department of Dakota, March 18, 1887.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING APRIL 2, 1887.

WAGGENER, J. R., passed assistant surgeon. Commissioned a surgeon on the 18th of March.

FITTS, H. B., passed assistant surgeon. Ordered to the Receiving Ship "Vernont."

TRACY, E. C., assistant surgeon. Detached from the "Vernont" and ordered to the "Atlanta."

HEFTINGER, A. C., passed assistant surgeon. Detached from the "Atlanta" and ordered on special duty in connection with construction of hospital at Widows Island, Me.

#### SOCIETY NOTICES.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT.—THE SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE will meet at 19 Boylston Place, on Wednesday, April 13th, at 7.45 o'clock. Papers: Dr. Henry Jackson, "A Case of Acute Infectious Universal Myositis." Dr. R. H. Fitz will open the discussion. Dr. F. C. Shattuck, "Four Hospital Cases. (1) Tetany; (2) Hemophilia; (3) Cirrhosis of the Liver; (4) Peritonitis, with Perforation of the Abdominal Wall." Dr. F. Minot will open the discussion. Dr. C. F. Folsom, "A Case of Multiple Neuritis (idiopathic). Drs. S. G. Webber and J. J. Putnam will open the discussion.

ALBERT N. BLODGETT, M.D., Secretary.

F. I. KNIGHT, M.D., Chairman.

GYNECOLOGICAL SOCIETY OF BOSTON.—The next meeting of the Society will be held at the Medical Library Rooms, No. 19 Boylston Place, on Thursday, April 14th, at 4 o'clock, P.M. Dr. I. W. Starbird will read a paper entitled "Puerperal Eclampsia." Dr. H. J. Harriman will also offer a paper.

H. J. HARRIMAN, M.D., Secretary.

CLINICAL REPORT OF SIX MONTHS' EXPERIENCE WITH THE PNEUMATIC CABINET, WITH TWENTY-SEVEN CASES.<sup>1</sup>

BY G. W. MCCASKEY, A.M., M.D.,

Professor of Diseases of Chest and Throat, Fort Wayne College of Medicine; Fellow of the American Academy of Medicine, etc.

In presenting to you my first clinical report of pneumatic-cabinet treatment, I will not detain you by a description of the apparatus used, or a discussion of the principles involved. I have received numerous letters from physicians, inquiring about the danger of accidents. I think these dangers have been somewhat over-estimated. With a single exception, I have never seen a syncope or hæmoptysis occur as even a possible result of the treatment. In this case (No. VIII), the patient spat up a teaspoonful or two of blood several hours after treatment. It was not the first hæmoptysis, and was not repeated, although the treatments were continued, and, I think, was simply a coincidence. Indeed, if the hæmorrhage is not from fragile, cavernous walls, but is due to over-distension of the capillaries, there can be no doubt that the relatively increased pulmonary pressure is curative. The lowering of arterial tension imperatively demands caution; but with the adoption of two inflexible rules (1) always to examine the heart; and (2) always to commence with *low pressures*, and *increase them gradually*—I believe that the danger is as slight as it could possibly be with any instrument of equal power. Here, as everywhere, whatever is potent for good may become, in ignorant or careless hands, powerful for harm.

In the treatment of phthisis, its dual relations to the lungs, on the one hand, and the system on the other, have been fully recognized. No "hobby" has been ridden, to the exclusion of those measures, the value of which has been attested by experience and observation. While the clinical histories of these cases constitute a record of experience with the pneumatic cabinet, yet it has been used as an auxiliary to recognized methods of general treatment; and there may often be an honest doubt as to how much is due to cabinet treatment, and how much to dietetic, hygienic, and therapeutic measures. After all, however, the most important question is: Are the results obtained by general treatment and cabinet treatment, jointly, better than those obtained by the former alone? If so, then the pneumatic cabinet has demonstrated its *raison d'être*, and should be regarded as an indispensable factor in the treatment of certain forms of pulmonary disease.

Cod-liver oil has been administered, whenever it was tolerated, in doses sufficiently large to be of service. When patients could only tolerate a half or one tablespoonful of a fifty per cent. emulsion (the usual strength of the various emulsions of the market), I have generally ordered it stopped, and used a substitute. Jaccoud says<sup>2</sup> that less than three ounces of oil (not emulsion) daily will be of but little service. Whether this rather extreme view can be fully indorsed or not, I am thoroughly convinced that the doses of oil ordinarily administered are practically useless. Glycerine has been used as the next best substitute; and when this was not accepted, sweet

cream, in doses of half a pint to one pint daily, has been advised. Pyrexia has been treated with quinine, salicylic acid, and antiseptic inhalations. Quinine has also been administered in some cases in tonic doses, alone, or combined with creosote, and sometimes iron, with or without the bitter tinctures.

For inhalation, the conventional spray of Hg. Cl<sub>2</sub> 1-1000, was used at first, to the exclusion of everything else. When this produced irritation, it was reduced to 1-1500 or 1-2000. A two per cent. solution of carbolic acid was used later on, but a one per cent. solution was found to be strong enough for the average patient. Among other sprays used were Dobbell's solution, five per cent. mixtures of pinus canadensis, and hydrastis canadensis. For the first three months, these sprays were simply projected into the external trumpet-shaped extremity of the breathing faucet, at the temperature of the room. Since then, medicinal agents have been carried into the lungs by means of an apparatus described elsewhere, which conveyed them in the form of saturated vapor, at an elevated temperature.

The records of cases will be made as brief as is consistent with a reasonably full appreciation of the condition of each patient.

CASE I. Male, unmarried, aged twenty-four. American, compositor; phthisis. Had winter cough for several years, which subsided every spring, until 1884. Had two attacks of hæmoptysis in April, 1885. From this time, cough and emaciation were continuous. Weight had fallen from 150 to 130 pounds. Under general treatment had gained seven pounds, when, on June 18, 1886, he was placed upon cabinet treatment. At this time, dullness on right side extended from apex down to second intercostal space, with almost pure bronchial respiration.

He was given one inch differentiation until July 8th, during which time he took ten treatments, with spray of 1-1000 Hg. Cl<sub>2</sub>. The improvement in symptoms was quite remarkable and continued after treatment was stopped. The patient removed to an adjoining State, but called December 5, 1886, in apparently perfect health. Weight 150 pounds, and no cough whatever. Dullness on percussion still remains. If absence of symptoms for five months can be regarded as satisfactory evidence of cure, then this patient has recovered, with probably fibrous transformation of tubercular area.

CASE II. Female, married, aged fifty-two, French; phthisis. Had ten children. Last one died "scrofulous," at seven months of age. Right lung: Dullness on percussion over upper and middle lobes, with cavernous respiration near apex. Patient came to the office with difficulty three times, after which she became bed-ridden, and died about one month later.

CASE III. Male, married, aged forty, German, saloon-keeper; phthisis. Healthy weight 190, present weight 170 pounds. Came under observation March 16, 1886. Health good until about two months ago, when he contracted a severe cold, and has coughed and expectorated ever since. Broncho-vesicular respiration at both apices, with very slight dullness on left side. Took fifteen treatments with Hg. Cl<sub>2</sub> spray 1-1000 and one-half inch pressure. The cough and expectoration, which were probably due to a concomitant bronchitis, rapidly subsided, leaving the broncho-vesicular respiration, but slightly, if any, modified. Patient summered at Northern health resort, and came

<sup>1</sup> Read before the Fort Wayne Academy of Medicine, December 15, 1886.

<sup>2</sup> "Curability and Treatment of Pulmonary Phthisis," p. 128.

home with nearly normal weight. Physical signs slightly improved.

CASE IV. Male, married, aged thirty-five, German, cigar-maker; phthisis. Right apex solid down to second interspace, with large cavity. Profound cachexia, with jaundiced hue. Healthy weight 135 pounds, present weight 115. Bronchial respiration at apex of left lung. Also tubercular laryngitis, with complete aphonia and dysphagia. Afternoon temperature, 102° F. Abundance of elastic fibres and tubercle bacilli in sputum.

Was only able to breathe against  $\frac{1}{4}$  inch of mercury, with 1-1000 Hg. Cl<sub>2</sub> spray, which was kept up daily for two weeks, and supporting treatment. He gradually sank, however, and died in one month from the commencement of treatment. While nothing was accomplished or expected in this case in the way of cure, yet the patient was made much more comfortable by the treatment. After the second treatment, he had the first night's rest for three weeks, owing to diminished cough, with bronchial irritation. Complete temporary relief was afforded the most distressing laryngeal symptoms by the application of a blister over the thyroid cartilage.

CASE V. Male, married, aged forty, American; fibroid phthisis. Left side: Dulness from apex down to fourth rib in mammary line. Bronchial respiration at apex, shading off into broncho-vesicular down to fourth rib. Marked retraction over infra-clavicular region. Right side: Percussion note fair throughout. Auscultation good, except expiratory murmur at level of third rib in front. No retraction. Chest expansion one inch: 29 $\frac{1}{2}$  to 30 $\frac{1}{2}$  inches.

Took fifteen cabinet treatments extending over one month, with one-half inch pressure and 1-1000 Hg. Cl<sub>2</sub> spray. Quite marked benefit as to symptoms, but without appreciable change of physical signs.

CASE VI. Female, married, aged forty, English; phthisis. Referred by Dr. A. P. Mitten of Columbia City. The case came under observation May 21, 1886. Family history good, except that one sister died of consumption at twenty years of age. Personal history: Never sick until October, 1885, when she took cold, and sore throat; has had cough ever since. Weight reduced from 130 pounds to 113 $\frac{1}{2}$  pounds. Appetite and digestion good.

Physical examination, in consultation with my colleague, Dr. J. S. Gregg, who has anxiously watched the progress of the case throughout. Left side: Inspection shows some depression in both infra- and supra-clavicular region. Complete dulness extending from apex down to fourth rib at outer margin of mammary region, and to second rib in front; posteriorly dulness extends somewhat lower than in front. Bronchial respiration heard over greater part of lung, with cavernous respirations just above second rib near outer margin. Crepitant râles in abundance from apex down to third rib with scattering sibilant râles. Right side: Very slight impairment of resonance over infra-clavicular region, with "jerky" and slightly harsh inspiratory sounds. Mensuration: Forced inspiration 30 $\frac{1}{2}$ ; forced expiration 28 $\frac{1}{2}$ . Afternoon temperature had been about 102°F., but the free administration of quinia by Dr. Mitten, before the patient visited me, had lowered and kept down the temperature to about 100° F. Pulse 120 to 130.

Patient was placed at once on cabinet treatment Hg. Cl<sub>2</sub> 1-1000 spray, with quinia continued in tonic

doses, and fifty per cent. emulsion of cod-liver oil in tablespoonful doses three times daily to be gradually increased. May 29th. Physical examination in consultation with Dr. Gregg, showed dulness unchanged. Auscultation shows clearly that more air enters upper lobe than at first examination. June 5th. Percussion shows line of dulness gradually receding from lower and inner margin of solidified area. June 10th. Emaciation has been continuous, reaching 111 $\frac{1}{2}$  pounds, a loss of two pounds since commencing treatment. From this time on, gradual increase of weight. June 13th. Cough much better. Night cough entirely relieved, and but little cough during the day. July 1st. Dr. Mitten writes me: "Found condition greatly improved. Dulness greatly lessened. Vesicular murmur partly restored. In fact, respiratory action of affected lung greatly improved. More improvement than I dared to hope for when she went to you."

At this time the margin of dulness had receded fully two inches below and in front. October 1st, "Feels about well." Auscultation discloses no râles, and I am unable to distinguish the cavernous murmur. Weighs 117 $\frac{1}{2}$  pounds. The pulse, however, has never been found below 96, and generally 108. Afternoon temperature 99 to 99 $\frac{1}{2}$ ° F.

In the early part of November, a circumscribed pneumonia developed in lower lobe of left lung which has only partially resolved. With this exception, the condition of the patient has remained about the same until date of writing, December 15, 1886, being still under treatment.

CASE VII. Female, unmarried, aged twenty-nine, American, dressmaker; phthisis. Right lung dull on percussion over upper half, with broncho-vesicular respiration. Daily treatment from July 1st to August 6th, was followed by marked improvement of both symptoms and signs. At this time she left the city for a month's vacation, during which the improvement continued. Treatment was resumed September 8th, and continued one month, with progressive improvement. Signs of primary infiltration have disappeared except over small area in second interspace where they were and still are (December 15th), appreciable. The patient has had two attacks of bronchitis as the result of exposure, for the last of which she is now taking cabinet treatment. An unpleasant, and I fear ominous feature of this case has been an intractable anemia, not influenced by chalybeates.

CASE VIII. Male, married, aged thirty-two, American, lawyer; phthisis. Strong family history of tuberculosis. One sister died of pulmonary phthisis aged thirty-one, and another of tuberculosis of the bowels aged seventeen. Of extremely nervous temperament; highly excitable. Came under my observation February 11, 1885, at which time he was suffering from severe and intractable lumbar pains, and cramping pains in the bowels. In consultation with Dr. H. S. Woodworth it was decided that the pains were neuralgic in character, and probably dependent upon chronic malarial poisoning from which patient had suffered for years, as evidenced by an enlarged spleen. On May 26, 1885, I took him to Dr. N. S. Davis, of Chicago, who, after a careful examination, expressed the opinion that the case would terminate in pulmonary phthisis. This opinion was based upon slight increase of vocal fremitus, with malnutrition, and family history.

Shortly after this the patient passed from observa-

tion, reappearing again April 25, 1886. At this time physical examination revealed bronchial respiration with slight dullness on percussion at right apex, extending some two inches below the clavicle. No râles. Resonance of left lung fair. Spleen very much enlarged and quite movable.

Took about one dozen treatments with different sprays, as all seemed to aggravate the laryngeal complication. Treatment was very irregular, and the patient again passed from observation with little improvement.

CASE IX. Male, unmarried, aged twenty-four, German, painter; phthisis. Dullness at left apex with broncho-vesicular respiration, and some crepitant râles. Marked general debility. Cough dry and persistent. Cabinet treatment with 1-1000 Hg. Cl<sub>2</sub> spray, with general treatment for about five weeks, resulted in disappearance of symptoms, and decided improvement of physical signs. Patient considered further treatment unnecessary, and has not reported for examination since, although members of his family tell me that he is apparently well.

CASE X. Male, unmarried, aged twenty-three, American, train despatcher; phthisis. Family history good. Personal history good until three years ago, when he contracted a severe cold. Since then has had occasional but not constant cough. Consulted me for acute bronchitis which resisted the usual methods of treatment. After six weeks of expectorants, sprays, and hopeful patience, the cough was absolutely unchanged.

Finding slight dullness on percussion over inner margin of right lung in second interspace, and over circumscribed area just below middle third of clavicle. I advised cabinet treatment. Five treatments, extending from May 22d to June 3d, with one-inch pressure, and 1-1000 Hg. Cl<sub>2</sub> solution as spray, absolutely cured the cough. The treatment was continued about one month longer with slight modification of physical signs.

CASE XI. Female, unmarried, aged twenty-three, American. Health good until she had a sunstroke in 1880, and hæmoptysis in 1883. Has badly-developed chest with dullness and broncho-vesicular respiration at right apex. Marked general debility with cachectic appearance. Commenced treatment on June 8, 1886, and continued for six weeks, taking two treatments weekly. Slight improvement which continues to present date.

CASE XII. Male, married, aged twenty-nine, American, mechanic; chronic phthisis: history of phthisis in family. Never sick until spring of 1880, when he contracted a severe cold and had cough, expectoration, and some emaciation during succeeding summer. In the fall was taken with "typhoid pneumonia" limited to left lung. Upon recovery cough ceased entirely, but came back in about three months, with expectoration. Condition has remained much the same since that time, except that in August of each year has been confined to his bed by cough and general debility. In winter gains ten or twelve pounds, losing it again in the summer.

At present (June 9, 1886) there is extreme general debility. Unable to walk more than a couple of blocks. Expectoration profuse. Chest muscles greatly wasted, with considerable retraction over upper half of left lung. Percussion note flat down to lower edge of second rib with impaired resonance two inches

lower. Respiratory sounds purely bronchial down to second rib, with crepitant râles over entire lung except at apex: cavernous murmur just below centre of clavicle. Resonance good on right side, except doubtful dullness in supra-clavicular region. Respiratory murmur rather harsh, but no râles. Heart sounds regular but rather tumultuous, and second sound greatly accentuated. Mensuration 29½ and 31½ inches. Respiratory capacity 100 cubic inches. Pulse 90, temperature 100° F.

Could not take cod-liver oil. Said he had tried it at least a dozen times, but "belched" it up for six or eight hours after, entirely destroying the appetite, and disordering digestion. Placed him on tonics and cabinet treatment, with 1-1000 Hg. Cl<sub>2</sub> spray, one-inch pressure. The first treatment caused a paroxysm of coughing lasting half an hour. The spray was reduced one-half, with little farther trouble. June 18th. Râles rapidly disappearing from lower lobe of lung. July 3d. Left lung continues to clear up in lower lobe, fewer râles, and more air enters upper lobe. July 29th. Just returned from two weeks absence. Rather more râles, but otherwise no change. Patient gained five pounds in weight, and walked to and from office, distance of a mile and a half. Improvement not continuing, treatment was discontinued November 6th.

CASE XIII. Male, married, age fifty-eight, American, farmer; phthisis, following typhoid fever. Dullness and bronchial respiration at apex of right lung, with great general debility.

Commenced treatment May 25th, and continued with several intermissions until November 1st. Great improvement both in physical signs and general symptoms. At this time he had an attack of dysentery which completely prostrated him, since which time he has not been able to come to the city for treatment; have not seen him since, though prescribing for him at intervals.

CASE XIV. Female, unmarried, aged twenty-three, American; primary infiltration of right apex, with chronic bronchitis. Marked anæmia, general debility and loss of ten per cent. of body weight, weighing 95½ pounds. Very slight dullness with broncho-vesicular respiration, in right infra-clavicular region. Placed on cabinet treatment with one-inch pressure, and supporting treatment. Improvement in this case was slow but continuous; and after four months daily treatment, covering May to August inclusive, was discharged apparently cured. Chest capacity has increased some ten per cent., and physical signs of disease have practically disappeared.

The only complaint which the patient makes is that she "catches cold" easily and has laryngeal irritation at such times. The diagnosis of phthisis was not verified in this case by finding bacilli in the sputum, but the points pertaining to symptoms and history were strongly corroborative. I believe now that this is a case of incipient phthisis cured; but the patient will probably remain under my observation for several years, and the future history will be duly reported.

CASE XV. Male, married, age thirty-eight, American, merchant; advanced phthisis. Family history bad. Had pleuritis (left side) twelve years ago. Some cough most of the time since. Marked dullness with bronchial respiration and crepitant râles from apex to second rib on right side, with cavernous murmur. Slightly harsh respiratory murmur at left apex,

and impairment of resonance of the lower lobe, probably the result of the old pleuritis. Weight reduced about fourteen per cent. — 140 to 120½ pounds. Respiratory capacity 150 cubic inches. Microscopical examination shows abundance of elastic fibres and tubercle bacilli. Was placed on cabinet treatment June 12, 1886, with one-inch pressure, and Hg. Cl., 1-1000 spray. July 21st. Respiratory murmur much clearer; signs of cavity more distinct. August 2d. Percussion of right lung seems a shade clearer. August 7th. Air enters right lung decidedly better. Respiratory capacity 162 cubic inches. Some laryngeal irritation. Laryngoscopic examination shows no signs of laryngeal tuberculosis. September 15th. Weight 125½ pounds; cough and expectoration diminished about one-half. At the present writing condition remains about the same.

CASE XVI. Female, unmarried, age twenty-seven, American, bookkeeper; dulness at right apex with broncho-vesicular respiration. Hacking cough, with no expectoration. Took cabinet treatment for one month with one-inch pressure. Cough and physical signs had about disappeared; the patient was discharged, and remains well.

CASE XVII. Female, age fifteen, American; phthisis. Bronchial respiration with bronchophony at apex of right lung, with crepitant râles. Considerable cough, mostly dry. Strong family history of phthisis. Healthy weight 121, present weight 101½ pounds. Took cabinet treatment daily for nearly three weeks; cough much improved; crepitant râles practically gone. Body weight 106½ pounds. At this time she felt able to resume her work which prevented her from continuing treatment. Have not heard from her since.

CASE XVIII. Male, married, age twenty-six, American. This patient had been leading an indoor life for several years, during which time he suffered from intractable chest pains which were thought to be intercostal neuralgia. At the left apex I found a peculiar harsh rough murmur, present at nearly every inspiration over a circumscribed area. There was no dulness on percussion. Several examinations at intervals of a week or ten days confirming the presence of an adventitious murmur of an obstructive character. I advised cabinet treatment, purely for its mechanical effect. About one dozen treatments were taken without apparent change of physical signs.

CASE XIX. Male, unmarried, age nineteen, student; advanced phthisis. Referred by Dr. W. P. Wherry. Five years ago had "typhoid fever and lung fever." Does not know whether one or both lungs were affected. Made fair recovery, but has had frequent colds and coughs ever since.

Present illness commenced a year and a half ago. Since then has had chilly sensations in the morning with fever in the afternoon nearly every day. Chest poorly developed; some depression on right side in infra-clavicular region. Well defined cavity in upper part of right lung, about three inches below clavicle. Cavernous signs most marked behind. Placed on cabinet treatment August 18, 1886, with one-inch pressure. October 1st. Does not cough as much as he did. Has been under treatment almost daily ever since, with considerable improvement of physical signs and general symptoms. General condition has improved materially with six pounds increase of body weight.

CASE XX. Female, married, age thirty-two, American; chronic bronchitis of several years standing. Cabinet treatment was carried out for three weeks with various sprays, without apparent improvement. Patient was hysterical, and probably exaggerated the symptoms, although there were physical signs of bronchial irritation. Has not reported for three months.

CASE XXI. Female, unmarried, age twenty-four, American; phthisis. Had been under observation at times for three years, during which time the physical signs — those of catarrh of the apex — gradually grew more pronounced. Came under observation last, on September 1, 1886, taking cabinet treatment for six weeks. Dulness on percussion was quite well marked at right apex, and over circumscribed area in third interspace. There was considerable improvement in both symptoms and signs; but the progress not being sufficiently rapid to suit her, she discontinued treatment and has not been seen since.

CASE XXII. Male, married, age thirty-five, American; doubtful lesion of left apex. Harshness of respiratory sounds, with slightly impaired resonance. Chest poorly developed. Took three treatments with some improvement of chest expansion. At this time he left for summer vacation, and was lost sight of.

CASE XXIII. Male, unmarried, aged thirty, farmer, American; advanced phthisis. Referred by Dr. Brown, of Wabash, Ind., September 29, 1886. Health always good until ten years ago, when he had what was probably remittent fever. The attending physician called it pneumonia; but, as there was neither cough, expectoration, nor chest pain, the diagnosis would seem doubtful. Health then remained about the same as usual until June 10, 1886, when he was taken with chills and fever, and was sick about one week. This time, the physician called it catarrhal fever; but, as there was cough and expectoration, it was probably lobar or lobular pneumonia. After this had continual cough, with slight expectoration. Got overheated in harvest-field, and from this on grew gradually worse. No hæmoptysis. Always subject to epistaxis. Poorly-developed chest, with great emaciation. Heart-impulse visible over extended area. Fair resonance over right lung. Left lung perfectly flat from apex down to nipple. Crepitant and fine mucous râles throughout greater part of left lung, front and back, with coarse, bubbling râles at base. Cavernous murmur and tympanic resonance just below nipple. Appetite and digestion very much impaired. Bowels moving six times per day. Pulse 110, temperature 99° F., at 5 p. m. Gave unfavorable prognosis, but patient had come to stay, and was, accordingly, placed on supporting treatment, with efforts to control diarrhoea, which was probably due to tubercular ulceration, and thus, perhaps, slow the inevitably fatal march of the disease. Very mild cabinet treatment was instituted, to satisfy the patient, but, of course, without benefit. At the end of two weeks I persuaded his father, who had hitherto refused to accept my prognosis, to take him home to die, which he did ten days later.

CASE XXIV. Female, married, aged thirty-three, American; advanced phthisis. Healthy weight 165, present weight 102 pounds. Family history good. Personal history: Health always good until spring of 1885, when she commenced having slight cough in the morning, with loss of flesh. In the following September she became too weak to do housework for herself

and husband. Menstruation ceased with commencement of the cough, since when there has been no "show" whatever. Has had chills every day, about 9 A. M., followed by fever, which usually reached its acme at noon. Digestion considerably impaired. Night sweats had been constant until two months ago, when they were stopped by six-grain doses of gallic acid, since which time they have not returned. Tympanic resonance and cavernous murmur at outer and upper part of right lung, with bronchial breathing down to sixth rib. No rales. Left lung: Bronchial breathing and dullness on percussion at apex, with a few crepitant rales. Organic changes less extensive, but apparently more active than in right lung. At 11 A. M., pulse 120, temperature 99.5° F.; 4 P. M., temperature 100.5° F. Gave unfavorable prognosis, but, at her husband's urgent solicitation, agreed to keep her under observation for a fortnight. Next day (October 8th), had chill at 8 A. M., and at 10 A. M., temperature was 104° F. Both the patient and her husband thought that the fever had frequently been as high as this during the last three or four months. Next morning, gave thirty grains of hydrobromate of quinia in three doses, with the result of a normal temperature all day. She took half-a-dozen treatments in the pneumatic cabinet, when I advised her to wait a few days, in the hope that, with the control of the fever, her strength would improve somewhat. The temperature was maintained at about the normal, and the patient taken home to await the result of the treatment of the pyrexia, upon which the rapidity of its fatal march was thought to depend. The improvement was quite marked after the cessation of fever, but her condition was not such as to justify her in returning to the city for treatment. In about one month the fever returned, and the case terminated fatally a few weeks later.

CASE XXV. Male, unmarried, aged twenty-seven, farmer; advanced phthisis. (Referred by Dr. G. N. Worley.) Father's sister died of consumption. No other case known in the family. Present illness dates from last January, and is referred to a long drive taken on a very cold, stormy day, although he was not conscious of "catching cold" until some ten days later. The first symptom was a dry cough, which grew progressively worse for about one month, by which time it became very bad. Broke down, while at work, in July, and had some form of pneumonia, which lasted three weeks. Had another attack August 28th, after exposure, also lasting three weeks, from which there is now only partial recovery. Has had some hæmoptysis and night-sweats. Always subject to epistaxis. Pulse 130, temperature 101° F. Lower lobe of left lung hepatized, with dullness at right apex, extending down to second rib; crepitant rales at right apex. Patient was under observation about two weeks, all the symptoms becoming progressively worse. Was placed in the cabinet two or three times, with very slight pressure. Was taken home, and died November 16, 1886.

CASE XXVI. Male, single, aged twenty-three; chronic bronchitis, dating from acute bronchitis in 1883. Last winter, commenced having a hacking cough, and has gradually failed in general health. Ten per cent. loss of weight. Took cabinet treatment three weeks irregularly, with some improvement.

CASE XXVII. Male, married, aged thirty-two; advanced phthisis. One sister died of consumption, and

father had some form of lung disease, but died of gastric cancer. One brother has chronic cough. Health good until five years ago, when he was awakened by a sudden cough, and thinks he spat up a pint of blood. Never had the slightest cough before this. Made fair recovery from this attack, but every winter since then has had about one month's sickness from prostration and cough. Never had a second hæmorrhage, except once last winter, while in Los Angeles, spat up a spoonful or so of blood. Right lung nearly solid, except a large cavity from third interspace to apex. Resonance fair in left lung, except slight elevation of pitch at apex. Afternoon temperature, 102° to 103° F.; pulse, 108. Endeavored to control pyrexia by hydrobromate quinia, and this failing, by salicylic acid, administered according to Jaccoud's plan; also carbolic-acid inhalation, but all without avail.

The patient took five cabinet treatments, while other methods were being used to counteract the pyrexia. There being no improvement, he returned home, a distance of fifty miles, and has not been heard from since.

No attempt will be made to classify the cases recorded, because any statistical facts, to have value, must be based upon more cases than are here reported, and upon cases observed for a longer period than six months.

The proportion of "improvements" could have been largely increased by refusing to treat the hopeless cases. But the chief duty of a physician, as I see it, is not to manufacture favorable statistics, but to combat disease, if he cannot realize the still higher goal of prevention; and I have no hesitation in doing what I have repeatedly done—make the last weeks of a consumptive more comfortable, even at the risk of utterly ruining my statistics.

## TWO CASES OF INSOMNIA.

BY S. G. WEBBER, M.D.

THE two following cases of sleeplessness are among the most severe and obstinate I have met in sane patients. They are of interest from the conditions which accompanied the wakefulness, the removal of which seemed to favor the recovery of power to sleep. Originally, both seemed to have been caused by mental strain, or by over-taxed brain; the abnormal condition, in one case of the skin, in the other, of the uterus, probably served as additional etiological factors, or to keep up the sleeplessness after it had once commenced.

Miss A., aged fifty-four, had never been well after having the measles at eighteen years of age. During winters she has been subject to colds, feeling "stuffed across the lungs." She never thought she had any nervous trouble until four years ago, when she received a shock from the sudden death of her mother, who was sick only one day. Her father is alive and well, eighty years of age.

After her mother's death she had the care of house-keeping; also looked after a small business of her own. She then began to have restless nights and "spells of nervousness," in which she would shake or tremble all over. She slept very little, and often could not lie down. She had considerable dyspepsia, distress soon after eating, acidity, and heartburn.

After poor nights, she had distress in her head and headache.

She thought that, formerly, she may have had some uterine trouble. At one time she wore a support, but she passed the climacteric without serious inconvenience. She had taken paraldehyde for many weeks, with the result of giving sleep, and with seemingly no bad effect. The quiet and freedom from home cares at first had a very beneficial effect, and sleep was more natural. Later, for a while, she slept well, after taking two grains of quinine at noon and at bed-time. There was much disturbance and loss of sleep, caused by two or three attacks of looseness of bowels, with some colic, possibly ordinary summer disturbance, or of nervous origin. Occasionally, it was necessary to give a dose of paraldehyde at night, but not frequently. On the whole, however, the sleep was very poor and these remedies were of only temporary benefit.

It was noticed that the skin was harsh and dry, and she scarcely ever perspired. A warm pack was given at bed-time for several nights. At first, this did not produce perspiration, and when the temperature of the pack was reduced, it had no effect until a dose of pilocarpine was given with it. When perspiration was free, the sleep was natural and refreshing. After eight days the pack was omitted. The pilocarpine, half-a-grain by mouth, was continued at bed-time. On the tenth day after trying the above treatment it is recorded: "Skin has a more natural feeling. She is better; is improved in appearance; has gained in flesh. Stomach don't give so much trouble. Can stay in room, and lie down with more comfort than for a long time."

The pilocarpine was reduced to one-sixth of a grain, and after two weeks it is recorded: "Patient is decidedly better. Sleeps five to six hours on an average, almost always without extra help. Can lie down with very much less discomfort." The urine was natural, acid, sp. gr. 1018, without albumen or sugar.

In this case, there seems to have been an intimate relation between the loss of function in the skin and the sleeplessness. Whether both conditions depended upon the same cause, or the loss of power to sleep was the result of diminished cutaneous action, may be questioned. She was not seen until the two conditions had been of so long standing, that I will not venture to decide the question. The power of sleeping was recovered in proportion to restoration of the function of the skin.

CASE II. Miss C., aged twenty-two, was never very well, though, from eleven to fourteen years of age, she enjoyed very fair health. The patient's father and father's family were healthy; her father died some years ago. Her mother is alive, a very nervous woman, and has severe headaches and neuralgia, and is a poor sleeper. The mother's mother is not well. One of her mother's sisters is insane.

At about fifteen years of age she was obliged to leave school. For two years previously she had not slept much. She was confined to her bed, and could see no one, except her mother, without screaming, laughing, and crying. Her head felt badly, and her back troubled her all the time. At times her legs ached, and she had pain in the joints. For two weeks before I saw her she had slept well.

The pupils acted naturally; the eyes, face, tongue, and limbs moved naturally. There was no trembling of hands; they were rather moist, as were also the

soles of the feet. There was lack of strength. Sensation was natural. Plantar reflex was slight; patellar-tendon reflex was natural. Heart and lungs were in a normal condition. There was no tenderness over the spine, but pressure on the muscles either side of the spinal column caused some discomfort.

After about two weeks she had an hysterical attack. Said she could not breathe; had much distress, agonizing for breath. Screamed two or three times, loud enough to be heard all over the house. Had pain in back, but head did not ache.

The chief unpleasant symptom was sleeplessness. When she could sleep, her head felt comfortable; if she lost sleep, she had more discomfort in her head. She was dressed and about the house most of the time; went out-doors, but was not able or not inclined to take much exercise.

Various means of inducing sleep were tried — rest in bed, hot baths, warm packs, cold douches to back, diet — but with only temporary success. Various hypnotics were used, with varying results. Paraldehyde would produce sleep one night, not the next. Urethane did no better. A pill containing camphor and lupulin caused sleep several nights. One containing camphor, extract of hyoscyamus, and extract of valerian also gave several nights' sleep, but both these, finally, had little effect.

On account of the distress in her head and headache aconitia was used, in a dose of two-hundredth of a grain. Not only was the head relieved but that night sleep was much more natural and refreshing. The aconitia was afterwards given frequently at bed-time with favorable results. It did not produce sleep every night.

She said a uterine examination had been made with negative result, so at first no such examination was made, but as the various means proved of no avail, one was proposed. The introduction of the fingers caused much nervous disturbance, almost an hysterical attack. No displacement was found, and no attempt was made to use a speculum on account of this nervous disturbance. There seemed to be considerable tenderness of the uterus and in the vicinity of the ovaries, therefore hot douches were ordered, and while taking these for awhile, she slept better.

About a month later, there being more distinctly marked pelvic disturbance with increase of headache, another examination was made, with a speculum. The hysterical excitement was less, or rather there was more self-control, possibly because sleep had been better. The cervix was quite large, the canal bled very easily, the cavity of the uterus was a little longer than normal, there was considerable excoriation around the os, thick mucus extruded from the os. Tincture iodine and glycerine were applied. About a week later another application was made, and one or two more in the next month. The congestion and excoriation were much relieved. The headache and backache were better and the patient slept much better. For a month she had only one or two sleepless nights, hypnotics were not given during a part of this time.

This case presents many points of interest. The hereditary tendency is moderately marked. The sleeplessness began at about the full establishment of the catamenia. The hysterical character of the symptoms was very well marked. Onanism was suspected but denied by patient.

Hypnotics were only of temporary benefit and the

milder kinds were of more continuous service than the stronger. The influence of the uterine disease upon both the headache and sleeplessness, was clearly defined. No remedy proved of much value until that was treated, the best results were obtained by combining with such treatment, aconitia, which restored the tension of the bloodvessels. During a large part of patient's stay in the asylum the arterial tension, as shown by sphygmograph, was much diminished. A few times, when she slept comparatively well, the tension was rather better, though this change was not constant.

December 23.

February 26.

April 29.

The tracings of December 23d, 24th, were taken after sleeping poorly, the latter the day after a dose of urethan, that of December 31st, was also taken after a dose of urethan, and does not show the same irregularity.

The tracings taken February 4th, 26th, and April 29th, were taken after uterine treatment was commenced, sleep was better and more natural; the last tracing was made while she was taking aconitia.

## RECENT PROGRESS IN CARE OF THE INSANE.

BY WALTER CHANNING, M.D.

### DEVELOPMENT OF THE COTTAGE SYSTEM OF PROVISION FOR THE INSANE.

THAT there is a world of transition and progress has shown itself in the care of the insane, as strikingly, perhaps, as in any movement during the last fifty years, instituted for the benefit of the helpless, or dependent classes.

Fifty years ago the population of the country was comparatively small; there were few lunatic asylums, and but little knowledge of the proper treatment of the insane. The proportion of this class to the community was practically unknown, as every lunatic was regarded as a family disgrace, and was hidden away and abused in the bosom of his family.

The ignorance and superstition then prevailing, which as usual went hand in hand, naturally prevented the proper provision being made adequately, as far as actual number went, for the existing cases of insanity.

Only fifty-eight years ago the first lunatic hospital, north of the Ohio River, was built, and that was the Columbus, Ohio, Hospital.<sup>1</sup> This was owing, however, largely to the newness of the country, though it is fair to presume not entirely.

If we take a period as nearly as possible of fifty years ago, we find that there was at that time a mere handful of asylums. This handful consisted of the asylum at Williamsburg, Virginia, opened in 1773, the first in America; a second at Staunton in the same State; the insane department of the Pennsylvania Hospital; Bloomingdale Asylum in New York; Friends' Asylum, Frankford, Pa.; Mt. Hope Asylum, Maryland; McLean Asylum, opened in 1818; Hartford Retreat; Vermont Asylum; South Carolina Asylum; Kentucky Asylum; and the Worcester State Lunatic Hospital opened in 1833.

There were in addition to these some private asylums, but excluding almshouses, no institutions of any size.

The first concerted and organized movement made, for the better care and treatment of the insane in institutions, may be said to date from the first meeting of insane asylum superintendents. I do not mean to say that previous to this time the condition of the insane had not changed considerably for the better, but organized, scientific action toward improved asylum construction and management, had not been possible.

This first meeting was held in 1844, at which time there were supposed to be twenty-five hospitals for the insane, thirteen of which were State hospitals. The total number of insane provided for was about fifteen hundred. If there were seventeen thousand insane

<sup>1</sup> Progress in Provision for the Insane. Dr. W. W. Godding.

persons in the whole population, or one to a thousand,<sup>2</sup> we see that less than a tenth were provided for. In considering these figures, however, we must always make allowance for their probable unreliability, as I have already intimated.

Taking the census of 1880, we find one hundred thousand insane persons, with nearly forty-one thousand of this number provided for, or two-fifths of the entire number, against one-tenth in 1844. Whereas in 1844, the number provided for may have been a fair indication of the confidence felt by the public in institution provision for the insane, the present figures are entirely misleading, as undoubtedly from one-half to two-thirds of the insane would be placed in institutions, if there were room for them. But the melancholy fact of the case is, that the insane hospital accommodation is miserably inadequate in this country, in almost all States.

This state of affairs is not owing to a lack of intelligent appreciation of the modern methods of care and treatment of the insane on the part of the public, though insanity is still viewed by many as a moral disgrace, rather than a physical disease, and lunatic hospitals are sometimes spoken of as prisons. It is largely due to the stupidity, narrow-mindedness, and timidity of legislative bodies. The members of these bodies seem to lose all freedom of judgment and action when elected, and are controlled by traditions, which make it next to impossible for them to appropriate money for any purpose, however good, unless political pressure is brought to bear on them. For this reason, more than for any other, thousands of the insane are at this moment exposed to suffering and sorrow, which it is sad to think of. Human sympathy is almost dead in the breast of the average legislator. He counts no cost but the money cost. If hospital care costs more than almshouse care, nothing more need be said to him; the almshouse is good enough.

As I have already said, the better hospital care and treatment of the insane began in 1844, with the organization of the Association of Insane Hospital Superintendents. These men were practical men, of scientific and executive ability combined, and they bent their energies largely to the construction of buildings for the insane. This was the precise direction at that time in which such energy was needed.

The first fruits of their deliberation appeared in their so-called "propositions" of 1851, which we can criticise easily enough now, but which were admirably suited to the time when they were promulgated. Dr. Kirkbride was largely responsible for these dicta, which showed him to be in advance of the time.

I have no intention of doing more than to allude to such of these "propositions" here, as have reference to building in general, that I may be able to contrast the changes and advances made in the general provision for the insane.

Proposition five, stated that "The highest number that can be treated with propriety in one building, is two hundred and fifty, while two hundred is a preferable maximum."

Proposition nine, which specified that no apartments should ever be provided for the confinement of patients, or as their lodging-rooms, which were not entirely above ground, seems strange to the casual reader, perhaps, of the present day, but such rooms have undoubtedly existed in a number of asylums, and

can be found to-day in almshouses. They should be entirely abolished.

Proposition ten, stated that "no class of rooms should ever be constructed without some kind of window in each, communicating directly with the external atmosphere." Such rooms were frequently constructed in lunatic asylums and less than half a century ago, I fear, in some of them. They were a relic of the dungeon treatment of the insane. These rooms still exist for the custody of lunatics in almshouses, and are only an additional illustration of the danger of trusting the insane to almshouse treatment.

Propositions fourteen and fifteen, provided that a large hospital should consist of a main central building for administrative purposes, and the wings for patients.

An additional set of propositions was adopted in 1853. This was chiefly in reference to the duties of the hospital staff (the word hospital was not much used in reference to the insane until 1850) and the employees.

In 1866 several important propositions were adopted, which, in the light of the twenty-one years' experience since, have been found to be, in the main, sound and true. These were chiefly in regard to the care of the chronic insane. The position was taken that the curable and incurable should be provided for in the same institution, the States being divided up into sections of convenient size, to furnish patients to a local hospital.

This method of provision is much the most satisfactory and convenient for the friends of patients, and for various other reasons, in general the best of all plans so far advocated. Many exceptions have, however, been made, and are still being made to the plan, partly by theorists, and partly by economists, who think of the cost first and the patient's welfare second. Perhaps the most notable exception, and in the early stages, largely in the nature of experiment, was the Williard Asylum for the Insane, at Ovid, New York, opened in 1869 for the custody of the chronic insane.

The Williard Asylum was the result of a combination of circumstances, which made it a possible success from the first. The poorhouses of New York were running over with unfortunate lunatics exposed to ignorant, and often inhuman treatment. They constituted a mass of old cases for which some better provision must be made. An immense institution, managed strictly on insane hospital principles, was what was needed, and Williard exactly fulfilled these conditions.

This asylum now contains more than eighteen hundred patients, and may, perhaps, grow to even larger proportions. No one can consider the history of the Williard Asylum, without a feeling of thankfulness that many thousands, of the most helpless and pathetic class in the community, have been saved from a life of suffering and misery, in the ghastly New York poorhouses, and made comfortable, and in many cases happy. But the Williard Asylum had an exceptional work to do, and its having done that work wonderfully well, in no way changes the exceptional character of the circumstances. The rule is proved by the exception.

The trustees, and superintendent Dr. P. M. Wise, both consider this point in their last report.<sup>3</sup> The latter says: "As a fundamental proposition, the divi-

<sup>2</sup> Progress in Provision for the Insane. Dr. W. W. Godding.

<sup>3</sup> Report of the Williard Asylum for 1886.

sion of the State into districts with an asylum in each district, located with a view to give easy access to the largest number seeking its accommodations, with hospital facilities for the recent, and capacity to care for the chronic insane as they accumulate, would seem logically correct. . . . Drs. Chapin and Cook advocated virtually a similar proposition nearly a quarter of a century ago. . . . In the meantime there have grown to completion, or nearly so, four State hospitals for the recent, and two great asylums for the chronic insane, located apparently without regard to future districts."

Hence, Dr. Wise thinks, that it would be unwise and embarrassing to change the general policy of the State, and he would advise the sending of chronic cases only to the Willard and Binghampton asylums. The trustees in general endorse the superintendent's arguments, but go farther, and suggest, that when all the asylums are completed and filled, buildings for the chronic cases can be erected on the grounds of those institutions now receiving presumably recent cases. This they think would be better than restricting the State.

It is safe to say, they suggest, what will eventually be done, as the most expedient plan for furnishing further provision. At a still more remote period, however, the State must be restricted, and all hospitals and asylums receive all kinds of cases. This may be one of those so-called questions of time, but it is none the less inevitable.

Another proposition adopted in 1866, though not unanimously, was to the effect that an institution "may" be enlarged to a point sufficient to receive six hundred patients. This, it will be observed, is a radical change from the dictum of 1851, which allowed a *maximum* of two hundred and fifty. Such a change of opinion showed that it was necessary to modify ideas to keep progress with the times, to say nothing of expediency. The insane, as well as institutions for them, were multiplying with unexpected rapidity, and either hospitals must be made larger, or a large number would be left unprovided for.

A point generally insisted on in these excellent propositions, was the need of elaborate classification. In the first set of propositions, eight sets of wards for each sex were recommended, and again in 1866, the importance of classification was emphasized.

To meet all the requirements in the case of the insane, such as convenience of access, light, heat, ventilation, classification, a main building with wings was designated in the propositions, and this plan was followed and developed, until it reached its climax, and turning point, at least in New England, in the hospital of the type of that at Danvers.

This hospital was intended to be the perfect embodiment of the practical experience and wisdom contained in, or deducible from the above proposition. Such it appeared to be in the early stages, but the unfortunate location, the poor construction, the deficiency in details, and the immense cost in proportion to the number of inmates, justly gave rise to criticism of this form of insane hospital architecture; primarily in regard to cost, and secondarily in regard to its adaptability to the purpose for which it was intended.

The latter criticism had already been frequently made of the close, congested, or linear type of hospital, and the erection of such palatial structures as the Danvers building gave fresh zest to the subject.

As is well known, a large proportion of patients entering insane hospitals, are cases of over two years' duration, or in other words, cases liable to remain as incurables. In view of this fact, as well as in view of the limited hospital accommodations all over the country, the great cost of the congested buildings, and the difficulty of obtaining the needed appropriations, the question of some different, and less expensive plan of building presented itself with renewed force.

The necessity of the old form of building was further shown to be less absolute than had been supposed, owing to the general advance made in the care of the insane. Mechanical restraint was rapidly lessening in amount, and with it, the bolts and bars and prison-like arrangements in other directions. It was found that insane patients could in many cases sleep in ordinary rooms, surrounded by ordinary furniture. They could take their meals together in large numbers, could sleep in large dormitories, and be trusted at large in the grounds without fences, or expensive stonewalls, which were earlier regarded as a necessary safeguard.

The next step taken was to apply this added knowledge in a practical direction, which was done by putting up detached buildings. These were first used for small numbers of selected cases, and regarded with some distrust, as experimental. So satisfactory were these buildings, however, that they were multiplied and duplicated in different parts of the country, until finally the hospital buildings at Kankakee, Illinois, were laid out on the so-called "village plan."

These buildings have already been described in the JOURNAL, but as many changes have taken place since they were last spoken of, it will be interesting to again refer to them.

The first point of interest in the history of this hospital, is the fact that its capacity was increased in less than two years from six hundred and thirty-nine to fifteen hundred patients, by the erection of new buildings. The superintendent, Dr. R. Dewey, thinks that no institution in this country has increased in number at an equally rapid rate.\*

The entire capacity of the institution is now sixteen hundred patients. The general plan of the buildings is a small linear building on the old plan, with a capacity of three hundred and seventy patients.<sup>5</sup> The balance of the patients are divided up in separate cottage buildings, scattered about on regular village streets. These buildings accommodate from thirty-three to one hundred and sixty patients. There are eighteen of them in all, accommodating twelve hundred patients.

Among the various detached buildings are infirmaries for each sex, bath-houses for each sex, an amusement hall, dining-room, kitchen, etc.

There is a fire-department annex connected with the male bath-house. This department has been perfected since the destruction of the South Infirmary by fire in January, 1885, when seventeen patients lost their lives. At the time this fire occurred, "the appropriation for fire apparatus had only been sufficient to put up the hydrants and lay the mains for bringing water to them, and in doing this a considerable additional amount had been used from the ordinary fund." Here again is an instance of the lamentable, and it

\* Illinois Eastern Hospital for the Insane. Biennial Report, 1885-6.

<sup>5</sup> Two sections of this building are semi-detached.

would seem, inexcusable tardiness of legislatures in making the most important appropriations.<sup>1</sup>

There are four hose-carts and a hand and ladder-cart in the fire-department building. There is a tower in the building in which is placed a bell, and in this tower the hose can be hung to dry. There is a central telephone station where a watch is kept day and night. From this station signals can be given for putting on pressure at the water-works, notifying the fire-department, etc. Scattered about the buildings are fifty-seven hydrants. Altogether the arrangements appear to be ample to prevent another large fire.

(To be continued.)

## REPORT ON MEDICAL CHEMISTRY.<sup>2</sup>

BY WILLIAM B. HILLS, M.D.

### THE RELATION BETWEEN UREA, PHOSPHORIC ACID, AND SUGAR IN URINE.

Bretet<sup>18</sup> has analyzed the urine of a large number of patients affected with diabetes. The quantity of phosphoric acid eliminated during the twenty-four hours was, on the average, one-tenth that of the urea. It fluctuates with the latter, but is much less affected both by the disease and by the treatment; thus, when the urea is a third less or a third more than the average normal quantity, the phosphoric acid deviates from the normal only by a sixth or a fifth, rarely a fourth.

No relation was found to exist between the sugar and phosphoric acid eliminated. According to the author phosphatic diabetes or phosphaturia is extremely rare. He estimated the phosphoric acid in the 24 hours urine of 798 persons. In 39 cases only the phosphoric acid exceeded four grammes. In 31 cases the amount was between four and five grammes; in 7 cases, between 5 and 5.6 grammes; in 1 case only, as high as 7.2 grammes. According to Bretet the elimination of sugar bears no relation whatever to that of the other urinary constituents.

#### SUGAR.

H. Molisch<sup>19</sup> describes the following new reactions for the detection of sugar: One-half to one cubic centimeter of the solution to be tested is mixed with two drops of a fifteen to twenty per cent. alcoholic alphanaphthol solution, and an excess of concentrated sulphuric acid is added. Upon shaking, in the presence of sugar, a deep violet color is developed, and upon dilution with water a violet-blue precipitate, soluble in alcohol and ether with a yellow color, or in potassium hydrate with a golden-yellow color, is obtained. If the alphanaphthol is replaced with thymol a deep red color is produced, and upon dilution with water a carmine-red flocculent precipitate, soluble with a pale-yellow color in alcohol, ether, and potassium hydrate, but with a bright yellow color in ammonium hydrate. Most kinds of sugar answer to these reactions; inositol, however, does not. Most glucosides respond sooner or later to the tests; indican is an exception. Urea, creatinine, xanthin, uric acid, allantoin, hippuric and succinic acids, phenol, and pyrocatechin

all give negative results. These tests are, according to Molisch, far more delicate than any other known tests for sugar, detecting the latter in solutions containing only 0.00001 per cent. Normal urine responds to these tests even when diluted with 300 volumes of water. Molisch considers, therefore, that the presence of sugar as a constant constituent of normal urine can no longer be doubted.

To distinguish normal from diabetic urine, Molisch recommends the following proceeding: (1) Dilute a specimen of normal urine and one of the urine to be tested for sugar with 100 volumes of water and compare the colors resulting from the application of the tests. (2) Dilute two similar specimens with 300 or 400 volumes of water. The diabetic urine will still respond to the test, while normal urine fails to respond under this degree of dilution.

Seegen<sup>20</sup> has submitted these tests to a careful examination with the following results: Sugar solutions containing 0.05 per cent. gave both reactions distinctly. Solutions containing 0.01 per cent. sugar gave with thymol a dark sherry-yellow color, with alphanaphthol a faint violet tint; but on dilution with water no precipitate was formed. The tests are therefore less delicate, according to Seegen, than Trommer's test. Normal human urine gave the reaction as described by Molisch. When the urine was diluted 100 times, a light red or violet color was obtained but no precipitate. Urea and uric acid gave negative results with both tests. But various animal substances and secretions, and chemically pure albuminous bodies, for example, peptone, egg albumin, serum albumin, and casein, all gave the reactions. These reagents, therefore, are of no value as tests for sugar alone, and Molisch's conclusion that sugar is a normal constituent of the urine is not justified.

In answer to Seegen, Molisch still maintains that his reagents are more delicate as tests for sugar than the Fehling's solution. In dilute solutions it is necessary to employ a small quantity of solid alphanaphthol in place of naphthol solution. With reference to albuminous bodies Molisch says that while these may give results resembling somewhat those obtained with sugar solutions, still the precipitates obtained upon dilution with water are, excepting in the case of peptone, all of a different color (dirty yellow or yellowish brown), from those produced with sugar solutions. Besides, they are all soluble in hydrochloric acid with a carmine-red or reddish-violet color, while the precipitate obtained with sugar solutions is insoluble in hydrochloric acid. Molisch now states that in place of sulphuric acid, hydrochloric acid may be employed in these tests, the mixture being subsequently boiled for a minute. Fibrine, vitellin, serum-albumin, egg albumin and peptone do not give the reaction when hydrochloric acid is used. Normal urine gives the reaction when boiled with alphanaphthol and hydrochloric acid, even if diluted ten times. Molisch still asserts that normal urine must contain sugar, or, otherwise, some body as yet unknown.

R. v. Jaksch<sup>21</sup> employs phenylhydrazine for the recognition of sugar. When a solution of hydrochlorate of phenylhydrazine, containing also sodium acetate, is added to an equal volume of urine and the mixture warmed for twenty minutes over a steam-

<sup>22</sup> Centralblatt für die Medicinischen Wissenschaften, 1886, page 708, from Zeitschr. f. Klin. Med. 21, page 20.

bath, there is obtained, in the presence of sugar, a yellow precipitate composed of needle-shaped crystals (a compound of phenylhydrazine and sugar). The melting point must be  $204^{\circ}$  C. Normal urine gives a negative result with this reagent. This test, according to the author, is more delicate than the ordinary tests for sugar. It does not react with other reducing substances besides sugar which occur in urine. Albumin, if present, must first be removed. The author found that the urine, in diseases of the liver, rarely contained sugar. The reducing urines passed after the administration of benzoic and salicylic acid, and in cases of poisoning by potassium hydrate and sulphuric acid did not contain sugar. Traces of sugar were found in the urine in cases of high fever; especially large in cases of ulcerative endocarditis. Sugar was found in the urine in three cases of carbonic-oxide poisoning, and in two cases of asphyxia following the inhalation of other poisonous gases.

Prof. Ottomar Rosenbach<sup>2</sup> has adapted the principle of the fermentation test, which theoretically is the most reliable means of discovering the most minute quantities of sugar, to the practical purpose of detecting sugar in the urine. A small quantity of the urine under examination, the reducing effect of which in a measured quantity of Fehling's solution (one cc. of the urine in an equal volume of Fehling's solution, whereby an incomplete reduction proves the presence of less than one-half per cent. of sugar) has previously been tested, is boiled, after the addition of a few drops of tartaric acid, which prevents the precipitation of the phosphates. The urine after cooling is divided into two portions. To one of these a small quantity of yeast is added and this portion is kept in a warm place. If after a few hours equal portions of each specimen be taken and each be tested with an equal quantity of Fehling's solution one of these as before, will reduce the solution, while the other, proportionate to the degree of decomposition of the sugar will give either a perfectly negative or at any rate a noticeably weaker result; so that a simple comparison of both solutions will show the difference. By this method extremely minute quantities of sugar will be detected with certainty as proved by Rosenbach's experiments on diabetic urine and on normal urine, to which traces of sugar had been added. The presence of albumin does not interfere with the application of this test.

### Clinical Memoranda.

#### BERI-BERI: A BRIEF ACCOUNT OF OUTBREAKS IN THIS COUNTRY AND OF SOME RECENT CASES NOT HITHERTO REPORTED.

BY FREDERICK C. SHATTUCK, M.D.,  
 Visiting Physician, Massachusetts General Hospital.

UNDER the head of "A Curious Endemic" I reported in the *JOURNAL* of October 27, 1881, an outbreak of disease on a Provincetown bank fisherman. Out of a crew of nineteen, fifteen were attacked by sensory and motor disturbances and oedema, beginning in the legs and extending upwards a variable distance on the trunk: two of the cases came under my observation in the Out-Patient Department of the Massachusetts General Hospital. No satisfactory cause could be assigned for the outbreak, and I was quite in the dark as to the nature of the malady from which the man suffered. Dr. Costello, of Vevay, Indiana, seeing the report, wrote to the *JOURNAL*<sup>1</sup> suggesting that the disease was beri-beri. This suggestion I could not at the time accept, for the reason that, as far as was known this disease was confined to the tropics and had never been known to originate in this country. The only recorded cases which I could find as having been seen in this country were in the Marine Hospital in San Francisco in 1880, and came from a Brazilian man-of-war.<sup>2</sup>

Subsequent reflection and events have convinced me that Dr. Costello was right and that the disease which broke out on the *Nellie Swift* was beri-beri. This outbreak, however, to the best of my knowledge and belief — and I have followed the question with some care since then — remains to-day the only one recorded as having originated in these latitudes. The fishing vessel on which it occurred was engaged the previous winter in the West India fruit trade; but other vessels of the same class had been similarly engaged in previous and the same years without any such consequences. Within the last four months the experience of the *Nellie Swift* has been brought freshly to my mind in the following way:

Dr. Séguin<sup>3</sup> reports three cases of beri-beri, originating in Cuba, the Isthmus and Brazil.

Again, Dr. Roosevelt<sup>4</sup> reports cases from the *Henry S. Sanford*, which sailed from Hong Kong for New York, July 20, 1886. Twelve out of eighteen were attacked and several cases were fatal. Some of the crew were treated in New York hospitals.

<sup>1</sup> December 15, 1884.

<sup>2</sup> Marine Hospital Report for 1881.

<sup>3</sup> *Phila. Med. News*, December 15, 1886.

<sup>4</sup> *Medical Record*, February 19, 1887.

Again, very recently, Mr. F. W. Anthony, of the Harvard Medical School, brought to me a sea-captain, a fellow townsman of his, who was the subject of a strange malady, to which none of the physicians whom he had seen could give a name, but which Mr. Anthony, fresh from preparing for a recitation including the subject of neuritis, suspected to be of that nature.

Captain R., sailed from Singapore for New York, July 10, 1886, after a stay of eight weeks at that port, during which time the officers and crew eat and slept aboard the ship. All went well until September 20th, when the second mate began to have swelling and numbness in the legs, without pain, accompanied by vomiting and loss of appetite. His countenance was natural, his tongue was clean, and the pulse was not markedly quickened. At first he kept about his work as usual, then had to give up in part, and November 9th he was obliged to take to his bed. November 16th he died, the swelling and numbness gradually making their way up to his chest before death. There was no delirium and until near the last he looked well in the face.

The first mate began to complain of the same symptoms October 20th, grew rapidly worse, gave up work November 1st, and died November 7th. The pulse was about 70, the tongue was darkly coated in the centre, and for two days before his death he was delirious.

October 25th, the captain's legs began to swell and grow numb and weak, but he had no vomiting. The swelling gradually increased and mounted, with impairment of sensation which was especially marked over the region of the bladder, and muscular weakness. It became difficult for him to move his head, but he succeeded in navigating the ship until he reached New York, toward the last of November. Since then he has been slowly improving, but is not yet well enough to resume his occupation. He is a temperate man, and of great bodily vigor, but when I saw him, March 20th, there was slight œdema of the legs with impaired sensation and muscular weakness. A slight patellar reflex could be obtained. Weakness in the arms was also noticeable. The urine was normal and, apart from a somewhat rapid pulse, a general examination was negative. On the arrival of the ship in New York, five of the crew entered a hospital with the same symptoms as had been presented by the officers, and three died.

Captain R. has of late been somewhat disposed to attribute the illness to canned string-beans, of which the officers eat freely, and which were sometimes of bad color. After the death of the mates he ordered the steward to give the beans to the crew. It seems, however, perfectly clear that the disease was a multiple neuritis, and that form of this affection which is called *beri-beri* in India, *kakke* in Japan. This conclusion seems to be placed beyond reasonable doubt by the outbreak on the *Henry S. Sanford*. Captain R. also told me that he heard of similar cases on a ship arriving in New York about the same time from the Philippine Islands.

It seems to me important that wide publicity should be given to these cases, so that physicians at our seaport towns may be on the lookout for them and promptly recognize their nature. It may well be that cases have occurred from time to time for years. It is only of recent years that the existence of such an affection as multiple peripheral neuritis has been known.

It is of special interest to note that the disease first appeared on the *Henry S. Sanford* and Captain R.'s ship, nearly three months after leaving port. The disease is endemic in portions, at all events, of Brazil, but the first case on the Brazilian man-of-war, to which allusion has already been made, occurred in Aden six months after the ship left Rio. The voyage was from Rio to Lisbon, thence through the Mediterranean, the Suez Canal, and the Red Sea. Between Aden and San Francisco there were a great many cases and eighteen were treated in the Marine Hospital at the latter city. The sanitary condition of the ship was reported as dreadful. Competent observers have studied the disease during life and after death, but I believe a Brazilian physician is the only one of these who considers it bacillary. The experience of these three vessels suggests that conditions favorable for the development of the disease may exist on the ocean as well as on land.

### A CASE OF HÆMOSPERMATISM.<sup>1</sup>

BY F. B. HARRINGTON, M.D.

In January, 1885, Mr. J. A., twenty-five years of age, a teacher in one of our institutions of higher education, a single man of good physique and of excellent habits, came for advice because of a slight enlargement of the epididymis of the right side. It caused slight pain after long standing or walking. The patient had never had gonorrhœa. The immediate cause of this epididymitis seemed to have been a long cold walk with insufficient clothing. Cold applications and a suspensory bandage soon brought relief to his trouble.

It transpired during the course of the questioning that there occasionally occurred a nocturnal emission which was reddish in color, and that the red color was also sometimes seen after straining at stool, and on one occasion after a cold sea-bath. There was no complaint of a frequent occurrence of these stained discharges, but they had caused the patient some anxiety.

About seven years ago the patient first noticed this discoloration of the semen. There occurred intervals during which there was no staining, and at no time were the losses frequent, occurring on the average once a month. Nothing about the patient or his condition suggested spermatorrhœa.

After the meatus had been snipped, a No. 29 French sound was passed with ease into the bladder, and caused no pain. There was no sensitiveness in the region of the prostate. Rectal examination showed no enlargement or tenderness of the prostate nor of the seminal vesicles. There was no pain on passage of urine or of semen, nor did movements of the bowels cause any distress. The patient had been accustomed to horseback exercise, but it never caused him any distress.

He was requested to bring any specimens which it was possible to save. During the course of several months the following specimens were obtained. Two pieces of cotton cloth stained a reddish-brown, cut from the night clothes, and a few drops of the fluid which were passed while straining at stool. This fluid

<sup>1</sup> Reported at a Meeting of the Surgical Section of the Suffolk District Medical Society on January 5, 1887.

was sent to Dr. Gannett, from whom I received the following report:

"March 12, 1886. The small specimen of fluid sent me on the 10th, shows, microscopically, numerous spermatozoa; a few red blood-corpuscles; a few granular nuclei; granules. It certainly deserves the name of a bloody seminal fluid."

The seminal fluid may be discolored in several ways. An admixture of pus changes its color from gray to white or cream color. An admixture of blood may change the color to a bright red, an orange, a light brown, a dark brown, or a dark red. A dark blue color<sup>1</sup> is occasionally seen, but its origin is not clearly understood.

The origin of the blood is generally believed to be in the seminal vesicles. An admixture may take place with blood from an inflamed urethra, but such a case would not be one of true hsemospermatisms. There are several causes for the appearance of the blood.

Vibert<sup>2</sup> says that slight capillary hemorrhages in the vesiculæ seminales are of frequent occurrence among the continent and among old men. The cause is here an over-distension and irritation of the vesicles.

Many authors (Lallemand, Ricord, Velpeau, Fournier, Gosselin, etc.), speak of bloody seminal fluid occurring after gonorrhœa. An extension of the inflammation to the seminal vesicles is a rare occurrence.<sup>3</sup>

Such inflammation is usually unilateral, affecting but one of the vesicles. By the rectum a hard or fluctuating mass can be felt, having the location and the general contour of the vesicle, but larger in size. There is pain on pressure and a constant dull pain which is increased by defecation, by micturition, by coitus, and emission.

Some authors claim that the blood comes from the epididymis or from the testicle, but it seems to be proven that the seminal vesicles are the usual source.<sup>4</sup>

A third cause, generally recognized by all writers upon this subject, is excessive coitus or masturbation. That such excess should lead to congestion and irritation is not surprising.

The character of the patient and his statements, lead me to believe that the cause of the blood in this case is over-distension of the vesicles. It may be possible that the discharge occurring at times after straining at stool, due probably to distension of the vesicles and to weakness of the ejaculatory duct, may have resulted from horse-back exercise.

The patient has been given fluid extract of ergot, and apparently with good results. The anxiety in the patient's mind has been allayed. He has been told that marriage instead of being contra-indicated, would probably be followed by a cessation of the symptom.

When we consider the moral effect upon patients of such bloody discharges, it is a little surprising that more has not been written upon the subject in our text-books.

Prognosis and treatment. In the continent and among old men, the condition, hsemospermatisms, is of little consequence. Marriage will probably be followed by a disappearance of the symptom in the former. The use of ergot seems to be followed by benefit in this case, and may be tried in all of this class.

In the second class, in which the blood comes from the inflamed vesicles, the symptom is liable to continue

as long as the inflammation lasts. Chronic inflammation of the vesiculæ seminales is of indefinite duration. To cause a disappearance of the symptoms which we are considering, we must cure the inflammatory condition.

In the third class, are those cases which result from excessive coitus or masturbation. Here to remove the cause is to effect a cure.

## Reports of Societies.

### SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION.

O. H. MONROE, M.D., SECRETARY.

MEETING January 5, 1887. DR. J. C. WARREN in the chair.

DR. GEORGE W. GAY reported a

#### CASE OF CHRONIC CYSTITIS IN THE FEMALE RELIEVED BY AN UNUSUAL OPERATION.

A widow, forty-eight years of age, had suffered more or less from cystitis for fifteen years, before coming under Dr. Gay's care. The symptoms were frequent and painful micturition; mucus, pus and phosphatic gravel in urine. There was very little pain in the region of the kidneys and ureters throughout the disease.

The treatment of the patient was varied and, as is frequently the case, the result was unsatisfactory to a great degree, until a resort was made to an operation described below. In the first place a trial was made with irrigation, a stream of warm water, medicated or not as seemed best, was allowed to flow slowly through the bladder for four, six, or even eight hours a day for six weeks. The symptoms improved temporarily under this treatment, but it finally caused so much pain, that it had to be abandoned. The urethra and meatus were then forcibly dilated sufficiently to admit the forefinger. The relief following this procedure lasted only two or three weeks. An artificial vesico-vaginal fistula was then made with Paquelin's cautery, but it was impossible to keep it open for any length of time, even after removing a section of the tissues about the fistula. Anything placed in the opening to keep it dilated soon became encrusted with the triple phosphates, and caused so much irritation, that it had to be removed. The parts were too sensitive to allow the patient to dilate the fistula with her finger, as is sometimes done. Finally the symptoms became so distressing, that opium failed to give any relief. The patient had chills, emaciation, delirium, and vomiting, and dissolution seemed near at hand, when as a last effort the following operation was performed: With a pair of strong scissors heated to a black heat all the tissues between the vagina below, and the bladder and urethra above were divided from the meatus to the cervix uteri, thereby laying open into one large cavity the vagina, bladder and urethra. The hemorrhage was unimportant. The object of this operation was to prevent the urine from collecting and remaining for any length of time anywhere between the kidneys and the meatus. This object was fairly well attained. The parts were very sore and painful for three or four weeks, but after that time she began to improve, and finally became able to ride, to go shopping, and on the whole, she enjoyed herself a good

<sup>1</sup>O. Guelliot. *Annales des Maladies des Organes Génito-Urinaires.*

<sup>2</sup>Nouveau Dict. de Méd. et de Chir.

<sup>3</sup>Van Buren and Keyes.

<sup>4</sup>O. Guelliot. *Annales de Dermat. et de Syph.* 1863, p. 204.

deal during the remaining four years of her life. She finally died after a fortnight's illness from vomiting, diarrhoea and coma.

Dr. Gay wished it to be distinctly understood that he advised this operation only in those desperate cases in which all other measures had been faithfully tried in vain, and in which death seemed inevitable, unless relief could be given within a short time. Under those circumstances he would not hesitate to resort to it again; should be satisfied if he succeeded in giving the patient as much relief as was obtained by the one reported above.

In conclusion, Dr. Gay expressed the wish that the discussion be not confined to cystitis in the female, as the same principles of treatment apply to the disease in both sexes. He stated that at the time this case was under his treatment the only antiseptic much used was carbolic acid. This he had tried in injections, but had found that hot water answered the purpose somewhat better.

Dr. E. W. CUSHING spoke of the great value of injections of bichloride of mercury (1 to 1500 or 2000) followed by iodoform emulsion in arresting fermentation, which fermentation he considered to be the element in the disease which we should especially attack. The emulsion was to be made by shaking up iodoform with gum-water and glycerine.

Dr. H. L. BURRELL remarked that in his experience with iodoform emulsion was confined to one case, and that in the male. He considered that caution was necessary in its use, and stated that iodoform once in the bladder was difficult to remove. To remove the iodoform used in his case required six or seven washings.

Dr. O. K. NEWELL called attention to the value of the *porte-remede*, of Dr. Dittel of Vienna, by means of which iodoform could be introduced into the bladder.

Dr. C. P. STRONG spoke in favor of injections of a saturated solution of boracic acid every day or two.

Dr. GAY spoke of the great benefit he had obtained in cases of phosphatic gravel from the daily use of good, hard cider. In several cases in which it had been necessary to remove calculi, every six or eight months with the lithotrite the gravel had ceased to form at all, even to collect under this treatment, and the patients had been relieved of their former troubles to a great degree. No drug in Dr. Gay's experience had produced such happy results in those cases, and he thought it deserved a further trial.

Dr. J. C. WARREN had operated twice for the production of an artificial opening in the female bladder in cystitis. There is no danger of an incurable fistula in these cases, as the chief difficulty lies in keeping them open. The edges of the mucous membrane of the bladder were stitched to the edges of the vaginal membrane to prevent closure. In one of these cases had he followed the patient through the treatment: a complete cure had resulted and the fistula was closed at the end of a year.

Cystotomy for the radical cure of enlarged prostate is an operation at present interesting to surgeons. It is chiefly employed to give good drainage to bladders which are so far advanced in disease as to resemble a pus cavity, but the sphere of this operation is likely to be extended in the future.

Dr. Warren did not use the double current catheter as the amount of liquid at one moment present in the bladder could not be so well regulated as by other

methods. Sir Henry Thompson limits the amount to four ounces, and prefers two ounces. The speaker had seen bad results follow the attempt to inject a larger quantity. Boracic acid is a valuable agent for this purpose; a four per cent. solution, which is not quite a saturated solution, is the strength commonly used.

The care of the catheter is one important point in the treatment. Custom varies greatly in this respect. During temporary use of the catheter, as in females after operation on the genitals, it is customary to keep the instrument submerged in an antiseptic solution when not in use. Such constant scrupulous care becomes difficult when it is necessary, as in a case of enlarged prostate, to use the catheter several times daily, perhaps for a lifetime. Thorough disinfection before and after use may, however, have a more important influence upon the future of a diseased bladder than the most elaborate internal medication.

Dr. E. H. BRADFORD stated that in two cases of chronic cystitis in the male which he had treated by drainage through a perineal incision, the relief was marked. He also considered that the operation was a much simpler one than it is usually thought to be.

Dr. F. B. HARRINGTON reported a

#### CASE OF HÆMOSPERMATISM.<sup>1</sup>

Dr. M. H. RICHARDSON called attention of the Section to some observations he had made upon the

#### SURGICAL ANATOMY OF THE ŒSOPHAGUS,

already published, for the sake of inviting discussion. At a former meeting of the Section Dr. Cheever had asked what caused the difficulty in passing a probang into the œsophagus during etherization, having himself met with the same difficulty in four cases. By Dr. Richardson special dissections had been made to determine this point. It was found that the ivory bulb of the probang became lodged in the lower part of the pharynx at the beginning of the œsophageal tube in all subjects where the trial was made. Continued efforts at its passage resulted either in penetrating the larynx or in rupturing the pharynx. When guided with the thumb and forefinger outside the neck it was made to enter the œsophagus. This was demonstrated by introducing the left forefinger into the pharynx from below, by left œsophagotomy.

The explanation offered is that in etherization as in death the pharyngeal muscles are relaxed and do not grasp and guide the instrument to the œsophagus. The bulb point of the probang pushes the relaxed pharyngeal wall ahead of itself and makes a path from which it cannot make its escape, and through which it may be forced by too great effort on the part of the surgeon.

Dr. E. W. CUSHING remarks that this relaxation of the pharyngeal muscles possibly explained why the pharynx appeared to be so large during etherization, and was able to hold so much mucus.

Dr. RICHARDSON thought this highly probable, and stated that during etherization deglutition did not take place.

Dr. WARREN called attention to the difficulty in passing the stomach tube in cases of opium poisoning; and said that the expedient of hooking forward the larynx had to be occasionally resorted to.

Dr. M. H. RICHARDSON showed a specimen of

<sup>1</sup> See page 326 of the Journal.

## MULTILOCULAR OVARIAN CYST.

The case was first seen in consultation with Dr. McCollester, of Ayer, December 11, 1886. The history briefly stated was as follows: The patient was forty-six years old and married. She first noticed a lump in her abdomen six years before. For several years it gave her no discomfort. Three years ago it had grown to such a size that its weight and pressure seriously incommoded her. She then consulted certain prominent surgeons. After examination the diagnosis of fibroid tumor of the uterus was made, and no operation advised.

The symptoms continued to increase in severity, pain was more or less constant, and emaciation followed to quite a marked degree. Some weeks before Dr. Richardson's examination, Dr. McCollester aspirated the tumor, which was now very large and fluctuating, and withdrew a rosy, brown fluid.

On examination I found a tumor filling the whole abdominal cavity, fluctuating and symmetrical. The uterus was somewhat adherent to it. General condition of patient good enough apparently to justify operating. The urine had been examined repeatedly by Dr. McCollester and no albumen found.

Dr. Richardson advised careful nursing and feeding, with tonics, for a week at home, and then that she should come to Boston for operation, if able.

December 20th she was brought to St. Margaret's, having borne the journey quite well, but still too weak for immediate operation. She was stimulated and fed, with rest and tonics, under which treatment she began immediately to improve. The operation was postponed from Wednesday, December 22d, to Thursday, if by that time she seemed strong enough to undergo it. Wednesday morning she was much stronger, and everything looked favorable for an operation the following day. At 8 A. M., she suddenly became comatose and died the next noon, with almost complete suppression of the urine.

Autopsy five hours after death. The tumor was found to be a multilocular cyst of the right ovary, attached everywhere by old adhesions. It was very easily shelled out of its attachments, however, and in doing this no vessels of any size were met with. The pelvic cavity was filled with one of the cysts and both ureters sufficiently obstructed to keep the pelvis of the kidneys distended with urine. The right kidney was much atrophied and both were in a state of parenchymatous inflammation. The uterus was normal in size. (Dr. Whitney.)

There are two interesting and important points connected with this case: the first is, the error in diagnosis (if we may believe the patient's story), made by experienced men. A tense ovarian cyst in close proximity to the uterus was mistaken for a fibroid tumor. An operation which at that time would have had every chance of success was therefore advised against. The second point emphasized by this case is the importance of early operations in ovarian tumors. This case was fatal because it was left too long. Had not the kidneys become already hopelessly diseased, the pressure on the ureters at the time of death was sufficient in my opinion to have caused at no distant day serious trouble in the pelvis of the kidney or in the kidney itself. Finally the adhesions which were found would probably not have been present at an earlier date, and the operation would have

been attended by much less risk. I am of the opinion that it is best to aspirate with a fine needle in all cases where the diagnosis of fibroid is not absolutely certain, and when the diagnosis of ovarian cyst is made, to proceed to its removal without delay.

## FORT WAYNE ACADEMY OF MEDICINE.

MEETING December 15, 1886.

Dr. G. W. McCaskey read a paper on

CLINICAL REPORT OF SIX MONTHS EXPERIENCE WITH THE PNEUMATIC CABINET, WITH TWENTY-SEVEN CASES.<sup>1</sup>

## DISCUSSION.

Dr. W. P. WHERRY. In cases where it is possible to accomplish anything the effect of cabinet treatment I believe to be beneficial. The pneumatic cabinet, I take it, is not a specific; but it is a very valuable adjunct, capable of aiding other treatment, and bringing patients on toward recovery. With its aid the class of incurable cases might be greatly narrowed. But while good results have been shown with this treatment it must not be forgotten that good results have been obtained without its use. But I believe that still better results can be obtained with it.

Dr. T. J. DILLS. I am glad to notice that Dr. McCaskey assigns the cabinet to the position of an adjunct to general treatment. As such it is undoubtedly entitled to recognition. In some of the cases which have been reported this evening the diagnosis does not seem to be fully sustained by physical signs, although I think that phthisis may exist without very marked physical signs.

Dr. CARL PROEGLER. I am pleased with the candid statements of the essayist, and think that good may result from the judicious use of the cabinet. The diagnosis should be made largely with the microscope, and should depend on the presence of the bacilli in the sputum.

Dr. M. F. PORTER. I would like to know whether Dr. McCaskey has carefully studied the vital capacity, and whether he has found it to vary as much as would be expected from the degree of consolidation present? Also whether there was any probable relation between the dysentery in the case mentioned (Case XIII) and the administration of the bichloride spray? The value of cabinet treatment could best be determined if those who were treating large numbers of cases would treat similar cases with the cabinet and without it, comparing results. I consider the cabinet a valuable acquisition.

Dr. MCCASKEY. In regard to the case of dysentery I do not think that it was due to mercuric chloride because the patient was convalescent from typhoid fever and had had persistent abdominal tenderness, which I think was due to incomplete healing of the enteric lesion. His son, aged twenty-seven, also convalescent from typhoid fever, had a similar attack of dysentery preceded by abdominal tenderness, although no mercury had been administered in any form.

I have been frequently impressed with the belief that the deficiency in vital capacity was not in proportion to the degree of consolidation. Some cases with slight lesions have greatly impaired vital capacity,

<sup>1</sup> See page 345 of the Journal.

while others with extensive lesions have a vital capacity greatly in excess of that which would have been anticipated. These discrepancies must depend largely upon the condition of the chest-wall, and probably are not greater than would be found among individuals with similar states of nutrition but not victims of phthisis.

The microscopical diagnosis of phthisis has a greater positive than negative value. The presence of Koch's bacilli must be regarded as pathognomonic; but it would be fatal procrastination always to wait for their appearance.

With reference to the diagnosis of certain cases with insufficient physical signs, I believe that the diagnosis of phthisis should be made in many cases much earlier than it is. If we are to attain satisfactory results and change the statistics of phthisis we must make early diagnosis. Whatever view we may take of the pathology of phthisis it must be conceded that the *very initial anatomical change* is inappreciable to the most skilled diagnostician by physical signs.

I am glad to notice that the judgment expressed in the opening remarks of the paper in regard to the relative position of the cabinet meets with approval. Nothing could be more deplorable than a tendency to elevate it to the position of a specific.

### Recent Literature.

*Diseases of the Lungs and Pleura, including Consumption.* By R. DOUGLAS POWELL, M.D., London, etc. 3d Edition. Rewritten and enlarged with illustrations. pp. 347. New York: William Wood & Co. 1886.

The title of the above work is somewhat misleading, conveying the impression that it is a complete treatise on diseases of the respiratory organs. The anatomy and physiology of the lungs and physical examination fill about fifty pages, pleurisy about fifty more, phthisis and its varieties one hundred and fifty, leaving less than one hundred pages for all other affections of the lungs and bronchi, and for the index. Broncho-pneumonia is dismissed in four pages, abscess and gangrene in two, oedema of the lungs in two more. In connection with the latter condition, no mention is made of the experiments by Welch showing that pulmonary oedema can be artificially induced only through paralysis of the left ventricle, the right continuing to act.

Thus the only two subjects at all exhaustively discussed are pleurisy and phthisis, others receive really less attention than in most of the standard works on the general practice of medicine.

We have no special criticisms to make on the chapters dealing with pleurisy and its treatment, except that the author, in speaking of free incision in empyema, makes no mention of one advantage of the Lister dressing in these cases; we allude to its valvular action, permitting the exit of air from the chest far more readily than its entrance, and thus materially aiding in the expansion of the lung as was first pointed out by Dr. A. T. Cabot,<sup>1</sup> of this city.

Among the rare cases mentioned by the author we note one of *right pulsating empyema*, and one of chronic serous effusion filling the left pleura, reaccumulating

after aspiration, but not impairing the usefulness of the owner, a policeman, during the four or five years he has been under observation. With regard to the bacillus tuberculosis the author takes a position of some reserve. "The characteristic lesions of phthisis are brought about by many causes, and furnish a soil upon which the tubercle-bacillus will readily grow. Epiphytic in nature, concomitant in time, neither the seed nor the fruit of the disease, it must nevertheless be allowed that the tubercle-bacillus takes an important part in the extension and conveyance of tubercular lesions."<sup>2</sup> Of phthisis he makes four varieties, the catarrhal, pneumonic, fibroid and tubercular. For diagnostic purposes the rapid staining of sputum by the method of Gibbs is considered all-sufficient. If the bacilli are abundant there is seldom any difficulty in detecting them by this method. If, however, they are few, and it is under precisely these circumstances that this aid to diagnosis is specially important, we have the high authority of Dr. Ernst for stating that Gibbs', in common with the other rapid methods, is not to be depended upon. Again, the author does not seem to be aware of the fact that Friedländer himself now agrees that the capsule in an accidental, not an essential part of his pneumo-coccus.

Having in a measure performed the duty of criticism, we can now allow ourselves the pleasure of praise, which is to be accorded especially to those portions of the book dealing with treatment, all marked by sound English sense, though sometimes less full than one has a right to expect in a work of so special a character.

F. C. S.

*Massage as a Mode of Treatment.* By WILLIAM MURRELL, M.D., F.R.C.P., etc. P. Blakiston. Son & Co., Philadelphia. pp. vi, 100. 1887.

It is but recently that we noticed the first edition of this readable little book. The second is much better arranged and has numerous additions. It calls attention to primitive and imperfect ways of doing massage, and insists on its proper administration, if satisfactory results are to be obtained. Like "Fat and Blood" this book will be read by patients as well as by physicians and doubtless through its influence many a chronic invalid who has come to a stand-still will insist on having massage tried, as the physician himself would, if he were the patient.

The second edition bears even a stronger resemblance than the first to its elder American cousin which it honors by quoting from more than from any other source.

D. G.

— Dr. Arthur Farre, F.R.S., died March 25th, at the age of seventy-seven years. He was honorary President of the London Obstetrical Society, Physician Extraordinary to the Queen, and accoucheur to Princess of Wales.

— A writer in the *Australasian Medical Gazette* describes a case of deafness of three weeks' standing, due to a cockroach in the ear. Until the offender was removed, the patient, an elderly woman, had no conception that she had been harboring any living creature, though she had had occasional sharp, stinging sensations in the ear. The remains of the cockroach, when washed out, were very offensive.

THE DOCTOR'S OVERCOAT.

THE doctor's overcoat may not look different from other overcoats and yet to an acute observer it tells the tale of its owner's daily life. No overcoat needs new buttons so often, or wears out so soon at the button-holes. Its sleeve linings melt away as soon as put in, and the doctor's wife uses it as a text on which to base a sermon for her good man's benefit, on the finfulness of unnecessary wear and tear of clothes, while the doctor himself, as he sees the newness of his outer garment disappear, sighs over the days of his youth when he did not feel it necessary to count the cost of his own garments in units of children's shoes and baby's diapers.

There are doctors who walk into the sick room with the overcoat closely buttoned about their forms, and thus save themselves the reproaches of their wives and miss the admiration of their tailors, but such visits are not often paid to the doctor's equals, and probably even less often to those whom he suspects may be his superiors. Occasionally when he visits a patient who is temporarily the occupant of limited quarters in a crowded hotel, he may escape the necessity of removing his outer garment, but even then his button-holes will hardly escape the inevitable wear, as he must take his prescription papers or his stethoscope from some inner pocket. The doctor may, however, wear his overcoat in the sick chamber in such a manner as to gain credit for unusual devotion, as when he runs in, in great haste, with his overcoat on, to make sure that Madame, the Lord Mayoress, can spare him for an hour to minister to the sufferings of the Marquis of Carabbas, but when he makes his daily call he will carefully remove his top coat before entering the sick chamber, and will seat himself by the bedside as though he expected to stay there for half the forenoon at least. That call finished, the overcoat is resumed and deliberately buttoned, while the exact condition of the patient is explained to the anxious relatives or the still more anxious landlady. At this point it is proper to signify that time is valuable, and the skilful

man will know how to say by the manner in which he buttons his coat and takes up his hat, "that, much as he desires to discuss the subject further, he has already done everything in his power, and unfortunately has no time for conversation." At each succeeding place the overcoat is removed and re-assumed until its buttons have been buttoned and unbuttoned some fifty or sixty or more times a day, according to the length of the doctor's visiting list.

It is an interesting question to consider whether it is possible to draw any inference as to the actual size of the doctor's practice from the state of his button-holes. Some acute observers have held that the physician who boasted of the extent of his practice, while his button-holes presented no sign of wear, must of necessity be guilty of prevarication, but the observer needs be careful how he draws such an inference without due knowledge of the relative resistance of the different fabrics from which top coats may be constructed, the strain to which the buttons are subjected by the accuracy of fit, the number of coats among which the wear and tear is distributed, and perhaps such other factors as the zeal with which the *frau doctorin* inserts the timely stitch which eludes observation and saves nine. Undoubtedly the practice is recorded in the button-holes, but to properly read the record would be possible only to those possessed of the special knowledge, at once of the manufacturers of woollen fabrics and of the intimate associate of the doctor's household. Public calamities and epidemics undoubtedly leave their traces, but written as it were in the sand, which the attrition of the often repeated buttonings of the daily routine, like the ebb and flow of the tide, entirely effaces.

It is a question of some importance with medical men of a thrifty turn of mind how to lessen the inevitable effect of daily use upon their button-holes, and various devices have been hit upon. The suggestion to do away with the outside garment entirely, except in weather of unusual inclemency, is not to be soberly regarded even for a moment; for, apart from any other consideration, the air of youth which attaches to an individual who wastes his body that he may save his clothes, would be a fatal barrier to the extension of his practice, and might finally compel him to dispense with shoes also. The adoption of a cloak which may be wrapped about its possessor without fastenings, would obviate many of the difficulties, but the cloak has become so exclusively the property of the stage brigand, that it would be impossible to recognize the merciful physician under so questionable a garb.

Perhaps the most feasible method yet suggested is that of dividing the buttons into sets or series or watches as the seamen are divided on ship-board, and using the different sets on different days, so that the first, third and fifth buttons shall be used on Monday, and those representing the even numbers on Tuesday. If the doctor is portly and his buttons consequently numerous, three relays or watches may be made. The double-breasted coat, by increasing the number of but-

ton—allows a still greater rotation, but the hidden button-holes of the single-breasted coat offer great attractions to those who feel that an evil is diminished when it is hidden from sight.

But why should you always remove your overcoat whenever you pay a visit, asks Madame, with an eye to thus diminishing the wear that she laments.

Ah! Madame, who is more appreciative than yourself of the air of deliberation with which your physician seats himself to study the unusual aspects of disease as manifested in the members of your own remarkable family? Could you describe the symptoms of the preceding hours with such accuracy of detail to a man whose dress showed that the necessity for hurrying on to the next patient was present in his mind even while he entered the room? Would not the overcoat tend to diminish the confidence you feel in your physician's care? The man who takes off his coat and goes to work at anything is popularly supposed to be terribly in earnest, and the man who attempts to solve intricate problems, and accomplish delicate manipulations involving human suffering and existence without taking off at least his overcoat might not unreasonably be suspected to be only half in earnest. The removal of the overcoat may be regarded as a sort of silent expression of the fact that for the time being the doctor's only business is to devote himself both intellectually and bodily to the patient before him. From the standpoint of his own welfare the doctor lessens the load he carries in ascending stairs by leaving his overcoat below, he adapts himself to the often too high temperature of the sick room and preserves for himself an extra covering when he regains the open air. He thus benefits both his patients and himself although he curtails the length of existence of his outer garment which, as it deteriorates till he is forced to lay it aside, cannot fail to remind him of the time when his tired soul shall lay aside its worn-out earthly garment to assume one which may not conform to the cut most in vogue at the present moment, but is constructed of most durable material.

#### ACADEMIC AND PROFESSIONAL COURSES OF STUDY.

THE aphorism that art is long and life is fleeting, impresses itself with a peculiar force, at the present day, upon the parents and guardians of young men, if not upon the young men themselves, for whom the usual academic course in Harvard College is merely preliminary to a subsequent course at one of the professional schools. Eleven years ago in his annual report, the President of the University said: "The average age of the young men admitted to Harvard College has been gradually rising during the whole of this century, until it has now reached a limit which had better not be exceeded." The average age had then risen six months in the preceding twenty years. Since 1875, however, the average age has risen four

months, students being now nearly nineteen years old when they enter, and nearly twenty-three when they leave the academic department.

Such a result is probably the inevitable consequence of the development of a College into a University, and of the attendant changes in methods of discipline and instruction and in courses of study. The serious drawbacks, however, entailed upon those subsequently training themselves for professional careers—drawbacks which are serious in proportion as that training is thorough—have for some years become more and more apparent. These drawbacks operate with especial force in the case of medical students as soon as any genuine attempt is made to raise the standard of medical education and to increase the requisites for a medical degree.

A young man who begins the study of medicine at twenty-three years of age, having previously secured his degree of A.B., is twenty-six years old before attaining the degree of M.D., (if only three years of study are required). Should he then gain a hospital appointment and spend a short time in other medical centres, or in travel—all of which are unquestionably desirable things to do—the age of twenty-eight or nine years will be reached before the actual practice of his profession and the attempt to become a producer instead of a consumer are begun. Such a person, in this country at least, is no longer a *young man*. The enthusiasm and elasticity which carry one through the inevitable drudgery and probable disappointments of the first struggle, are, to say the least, somewhat chastened.

Strongly impressed by these facts, and undoubtedly hampered by them in attempts to lengthen the medical course from three to four years, the Medical Faculty of Harvard University have recommended to the consideration of the Academic Council—a body representing the undergraduate department as well as the various schools—the expediency of granting the degree of A.B. to all undergraduates who shall subsequently take the longest course of study offered at the professional schools after three years' attendance (at the end of the junior year) in the Academic Department. The professional degree and that of A.B. to be given simultaneously at the end of the professional course, it being understood that the requirements of each have been fulfilled. The first year of a professional school would thus be made equivalent to the present senior year.

In his remarks supporting this recommendation, Dr. H. P. Bowditch, the Dean of the Medical School, showed from various tables and statistics, that foreign systems of university education enable students of medicine to enter upon their life-work at least two years earlier than is possible with us—even for those beginning to practice immediately upon receipt of a degree—and that this result is reached without any loss but with a positive gain in the thoroughness of the professional training.

In Germany, the best class of medical students begin

their professional studies at a little earlier age (18.4 years) than that at which young men enter Harvard College; the course of study lasts five years and the German physician is ready to begin practice before he is twenty-three and one-half years old. In England, four years are required to complete a course of medical study, and a large majority of English physicians begin the practice of their profession before they are twenty-four years old. In France, a complete medical course usually occupies six years, and a French physician usually begins to practice his profession at about twenty-four years of age.

Dr. Bowditch himself, and no doubt many share his view, is ready to go farther than the recommendation of the medical faculty to the council, and to advocate more radical measures. In his opinion, a simple consideration of the way in which the academic department has been developed in recent years will hardly fail to produce the conviction that, in all the changes which have there taken place—changes which have raised the age of graduation—the function of this department as a preparatory school for a professional career has been much less prominent than its other function of providing a liberal education more or less complete in itself. The question, therefore, suggests itself to his mind, whether an organization may not be devised which, while retaining whatever may be of value in the old method of compulsory training, shall permit the elective system to develop itself even more freely than it can under present arrangements. For such an organization he proposes:

(1) An academic course of three years with requirements so graded as to lead to the degree of A.B., at an average age of twenty years. (2) A philosophic course of three years with requirements so graded as to lead to the degree of A.M., or Ph.D., at an average age of twenty three years.

As Dr. Bowditch truly says, such an academic department would, in respect to the age of its students be very much what it was twenty-five years ago, and its graduates would be prepared to enter any of the professional schools, or to continue their course of liberal study under the direction of the philosophic faculty.

Such radical changes as are here suggested, will naturally excite antagonisms and could only be adopted after thorough discussion, which they certainly merit, for there is much to recommend them. On the other hand, the proposal that the first year in the professional schools may be counted as the fourth academic year, under certain contingencies, ought to commend itself immediately, and its adoption is, in fact, essential, if higher standards of professional education—especially of medical education—are to be made permanent and practically serviceable.

—There were 187 degrees of M.D. conferred at the sixty-second annual commencement of the Jefferson Medical College, Philadelphia, which was held April 5th.

## INTUBATION OF THE LARYNX.

It is almost too early to pass judgment as to the place which this new operation is to have in the therapy of the future. Is it destined to supersede tracheotomy in the treatment of diphtheritic affections of the upper-air passages?

Theoretically, it seems a simple matter with an applicator shaped somewhat like a male urethral sound, and the aid of the *tactus eruditus*, to pass over the back of the tongue, by the epiglottis, and into the wind-pipe, a little gold-plated tube, skilfully contrived exactly to fit the larynx, and with a collar to rest on the arytenoid cartilages, so that it will keep in place; practically, however, the operation (both the placing *in situ* and extraction of the tube) is one of singular difficulty, not comparable with laryngotomy in respect to the ease and facility with which the latter operation can ordinarily be performed; and we pity the practitioner, who, without considerable previous practice on the cadaver and on the healthy child, shall, for the first time, on a struggling and strangling infant, attempt to perform intubation with O'Dwyer's instrument.

Dr. O'Dwyer, however, deserves great credit for having brought before the profession a method of treatment, which, possessing none of the terrors which tracheotomy has to the common mind, must in certain circumstances, and in the hands of experts who are perfectly familiar with all the details, sometimes save life where, doubtless, every other means would fail. Nor can it justly be said that he has simply revived and improved upon the older process of Bouchut, which by its very clumsiness, and the impossibility of its meeting the indications required of it, had fallen into oblivion. Dr. O'Dwyer's cases now number something more than forty-eight; of these twelve, or one-fourth have recovered; a result which compares very favorably with the statistics of tracheotomy. Northrup<sup>1</sup> reports twelve cases, and claims five recoveries. Dillon, of the New York Foundling Asylum, has operated fifteen times, with five recoveries, Dr. F. E. Waxham, of Chicago, has published thirty cases of which fourteen recovered. Dr. Hance, of the Nursery and Child's Hospital, has reported five cases with one recovery. Jennings, of Detroit, has operated four times; all his cases died. He prefers tracheotomy, and says: "In my experience fully seventy-five per cent. recover after tracheotomy." Dr. Northrup in summing up the results,<sup>2</sup> gives a sum total of 165 cases, done to date, with 28.05 per cent. of recoveries; Chicago alone has furnished ninety-six of these cases with twenty-nine favorable results, or 30.02 per cent.

Since these reports were published, Dr. G. W. Mason, of Bloomington, Ill., has put on record three cases,<sup>3</sup> only one of which was saved. He thus sums up the advantages of intubation: "(1) It involves no

<sup>1</sup> New York Medical Record, Vol. 30, p. 467.

<sup>2</sup> Medical Record, December 11, 1896.

<sup>3</sup> Medical News, March 26, 1897.

cutting, and is bloodless; (2) parents and friends readily consent to it, when they would not to tracheotomy; (3) it gives a larger percentage of recoveries; (4) there is no perceptible shock after the operation; (5) There is no risk of systemic infection, because of an open wound; (6) it does not expose the lungs to inflammation by the air not being prepared for inhalation by passing through the upper-air passages; (7) it does not preclude a subsequent tracheotomy."

#### THE CENTENNIAL OF COLUMBIA COLLEGE.

THIS week Columbia College is celebrating, with appropriate ceremonies, the one hundredth anniversary of its revival after the Revolution. In 1787 it was reorganized by an act of the State Legislature which confirmed the royal charter granted in 1754 for the establishment of a college in New York and also changed the name of the institution from King's College to Columbia College. In 1749 a lottery was authorized by colonial law to raise money for the founding of a college, and by this means the sum of £3,443 18s. was raised, and in 1754, the same year the charter was granted, the Rev. Dr. Samuel Johnson, of Stratford, Conn., accepted the Presidency of the proposed seat of learning. The first college building was erected, on land presented by Trinity Church, in the year 1756.

The second President was the Rev. Dr. Myles Cooper, who succeeded Dr. Johnson in 1763. He was a strong Tory and excited so much indignation by his efforts in support of the King, that his lodgings were attacked one night in May, 1775, and he was obliged to take refuge on board the British man-of-war *Kingfisher*, on which he soon afterward sailed to England. It was during his Presidency, in 1765, that the Medical School was started; and the students in this department were the only ones who were not, at this time, required to lodge and take their meals in the college buildings. During the Revolution the students were dispersed, and the buildings were used as barracks and hospital by the American troops.

In 1787 Dr. William Samuel Johnson, son of the first President of King's College, was inaugurated the first President of Columbia College, and during his term of office the Medical School was more firmly established by the appointment of a Dean of the Faculty and several medical professors. In the beginning of the present century, Dr. David Hosack was professor of botany and materia medica. He collected an excellent library, and, having failed to secure land from the State for a botanical garden, he leased from the city corporation twenty acres of ground between what are now 47th and 50th Streets and Fifth and Sixth Avenues, a district then far out in the country. This property, which, with \$10,000, was afterwards given to the college by the State, now constitutes a considerable portion of its wealth. The Rev. Dr. Barnard, the present incumbent, was elected to the Presidency

in 1864, and has held the position longer than any of his predecessors.

The Medical School, established in 1767, existed until November, 1813, when it was consolidated with the College of Physicians, which remained entirely distinct from Columbia College until 1860, when it became formally recognized as the medical department of the college. The School of Mines, which was organized in 1864, has had a most successful career, and the associated departments of the college now have nearly 1,600 students in them, of whom 604 belong to the Medical School. The magnificent Vanderbilt benefactions will, of course, eventually, if not sunk in bricks and mortar, make the latter the most completely equipped and expensively appointed school of medicine in this country.

#### MEDICAL NOTES.

—The *Medical Record* gives the following as the composition of the patent asthma cure, which Dr. Holmes in his "One Hundred Days in Europe," says gave him more relief than any other of the many remedies that were showered upon him.

R. Pulv. lobellia,  
Pulv. stramoniac fol.,  
Pulv. potas nitrat.,  
Pulv. black tea . . . . . 33 3 ij.

M. and sift.

Some of this is burned and the smoke inhaled.

—Lord Lytton need not have restricted his celebrated aphorism regarding the comparative might of the pen and the sword as he did. Even outside "the rule of men entirely great," the sword has become, in these latter days, quite a feeble and useless thing. Colonel Paul Methuen stated recently, in the course of an address which he gave at Toynbe Hall, in London, that in the Franco-German war, only six Germans owed their death to the sword, and that the total number wounded with this weapon, with which the Romans conquered the world, was only two hundred and twelve. But all this is saying nothing about the rifle, the revolver, or even the toy-pistol. The average boy finds the latter weapon more effective, and infinitely easier to wield, than the pen; while the daily records of the press show that a considerable portion of the community put their trust, in times of storm and stress, upon the seven-shooter, rather than upon the stylographic pen.

—A meeting of anti-vivisectionists recently held at Edinburgh, recorded a protest against the "memorial recently presented to the Royal College of Surgeons praying that the bequest by Sir Erasmus Wilson should be devoted to the foundation of an institution for physiological and pathological research."

—A correspondent of the *Chicago Medical Journal and Examiner*, writing from the La Pitie Hospital, in Paris, gives the following caustic description and comments regarding the conduct of a laparotomy which he there witnessed: "At this hospital, I saw

the most bungling laparotomy I have ever seen performed, excepting, perhaps, one ten years ago, performed by a gynecologist, who was at that time, and is even to-day, recognized as one of the first authorities in England. To see what a perfect failure two such great authors on the subject of diseases of women are, when they attempt to do an ovariectomy, has led me to the conclusion that there is an especial skill required for the performance of this operation, which a few men possess, and many cannot acquire. This man's idea of antiseptics was evidently the use of the spray; for while the room was so full of the vapor of carbolic acid that one could hardly breathe, one of his assistants had just finished dressing a woman's leg affected with acute phlegmasia dolens, and went directly from the case to the operating room without changing his clothing. The man who handed the instruments had dirt under the finger-nails, and the numerous assistants who attended to the sponges did not wash their hands after coming into the operating room. The cyst was one of the broad ligament; it had a great many attachments, and the operation was a difficult one. The patient died twenty-four hours after the operation, but whether from carbolic-acid poisoning, or from the operation itself, I was unable to settle in my own mind."

## BOSTON AND NEW ENGLAND.

Two cases of small-pox were lately reported from Huntington, among employes of the Chester paper company. An investigation of the circumstances by the Secretary of the State Board of Health, showed that rags were the probable medium of contagion, but whether domestic or foreign rags, it was impossible to determine definitely. A portion of the domestic rags were from New York where small-pox has been prevalent of late, and the probability seemed to Dr. Abbott to be in favor of these rags as being the medium of contagion.

The medical profession in Maine seems to be still in doubt as to the actual facts regarding the passage of the Medical Bill, which was at first said to have received the governor's approval, and was later said to have been vetoed. There are now rumors that the page of the record containing a signed bill has been cut out and is not to be found. An investigation is expected, pending which some of the incorporated bodies within the State maintain that the act is law.

A fire last week in the building occupied by Messrs. Wright & Potter, State printers, destroyed a large quantity of printed reports and other public documents, among them the entire edition of the forthcoming Report of the Massachusetts Board of Health, which will consequently have to be set up and printed anew, thus causing a considerable delay. This is, we believe, the third or fourth, more or less serious fire which has taken place in the premises of this firm, and this recurring misfortune has a peculiarly disastrous effect upon those departments whose work is so closely dependent on the prompt transaction of the public printing.

The Judiciary Committee gave a hearing at the State House, April 6th, on the expediency of legislation to improve the methods of using expert testimony in court. The presence of a large number of prominent physicians attested the interest of the medical profession in the subject. The draft of a bill was submitted by T. W. Tyndale, Esq., who appeared as counsel for the Massachusetts Medico-Legal Society. The provisions of the bill were similar to those of a proposed bill, printed upon page 120 of this volume of the JOURNAL. Drs. Francis Minot, H. I. Bowditch, B. E. Cotting, Theodore Fisher, E. S. Wood, and others addressed the Committee in behalf of improved methods of using expert testimony in court.

The disappearance and probable death of an insane pauper who escaped from the almshouse at Prescott, Mass., led to an investigation of the place by the State Board of Lunacy and Charity. The investigation resulted in a report that the building was unfit for its purpose; that a ball and chain had been used on the legs of inmates; that they were confined in small, loathsome rooms; that the patient who disappeared, and whose remains were subsequently found about a mile from the almshouse, had jumped from a window and tried to get away in the midst of a snow-storm, having been previously maltreated.

We referred to the condition of the pauper insane in some of the almshouses in this State in an editorial, March 17th last.

## NEW YORK.

The fifty-seventh annual commencement of the New York College of Pharmacy was held at Steinway Hall, March 29th, when the Rev. Dr. Robert Collyer delivered the address to the graduating class, which numbered eighty-three.

The New Jersey State Board of Health met on April 8th, and discussed the legislation enacted in the interest of the public health during the session of the Legislature just ended. Included in this are new laws, securing the enforcement of the act in reference to the adulteration of foods and drugs by the Dairy Commissioners and the Milk Inspector. The State was reported to be in an unusually healthy condition, except as regards measles, which is epidemic in several cities. There is a slight outbreak of small-pox at Plainfield, but the small-pox in Atlantic County is well under control. There is said to be an increase of pleuro-pneumonia in Hudson County.

It has been decided by the Committee in charge of the Marion Sims monument fund, of which Dr. George R. Shrady, editor of the *Medical Record*, is Chairman, that no award of a design will be made until the autumn. The other members of the Committee are Drs. William T. Lusk, Fordyce Barker, Thomas Addis Emmet, and William M. Polk; and, largely through the efforts of the *Record*, about \$7,500 have been subscribed. For some time past, ten designs for the proposed monument, selected from a considerable number offered in competition, have been on exhibition at the hall of the Academy of Medicine,

and these are by the sculptors, Wilson MacDonald, Alexander Doyle, Giovanni Turini, and Carl Schmidt. The monument is to be a standing figure in bronze, and it will probably be placed in Central Park.

## Correspondence.

### AXILLARY LUMPS.

6 NOTTINGHAM TERRACE,  
YORK GATE, N. W. LONDON,  
March 29, 1887.

MR. EDITOR.—Those of your readers who have cared to follow the correspondence on the above subject will not fail to observe that Dr. E. T. Williams has dropped the statement that the cases by Scarpa, Siebold, Moore, Lee, and Stanley were "quite similar to those described by Champncy" (whose name, by the way, is misspelt). He now drops all these but the case of Siebold, whose case he still thinks is of the same kind as those described by Dr. Champneys (not "Champncy.") It may be so; I say it cannot be proved from Siebold's description, and I have already referred to the differences.

Dr. E. T. Williams talks about the advisability of treating "the uncleanliness and uncleanness of a constantly oozing tumor of the armpit," by a surgical operation. From this I gather that he cannot have read the course of these lumps in the original. Several inaccuracies occur in the annotations, from which alone Dr. E. T. Williams appears to have drawn his information. It is no business of mine to save him the trouble of referring to the author's original description for more precise information, and I shall write no further letters with this object.

Had he been accurately informed he would scarcely have considered operative procedure "fair practice," even though a specimen might be thereby procured for microscopic examination.

These "lumps" have doubtless existed for centuries, but that much concerning them remains to be learnt no one will deny; certainly their describer says no word in any other sense. Now that Dr. Champncy's description has at one and the same time afforded a means of recognizing their character and drawn special attention to their prevalence, accident may be trusted to provide a pathological specimen in the near future. For this we must be content to wait patiently.

Yours truly,

ROBERT BOXALL, M.D.

## THE DISCUSSION OF THOUGHT-TRANSFER- RENCE AT THE SUFFOLK DISTRICT MEDICAL SOCIETY.

14 DEAN'S YARD, WESTMINSTER, LONDON,  
February 23, 1887.

MR. EDITOR.—Will you allow me space for a few comments on the interesting discussion respecting thought-transference, which I find reported in your issue of February 3d. Dr. Morton Prince's presentation of the case struck me as extremely able and fair; and both he and Professor Royce expressed with regard to it just that scepticism (in the proper sense of the term) with which it ought undoubtedly to be approached. But some of the subsequent speakers seemed (partly, perhaps, owing to the necessary condensation of their remarks in your columns) to do our English work somewhat less than justice.

Mr. T. W. Higginson's attitude is a little puzzling; for though he is so circumstanced that he might fairly have blessed us, his utterances have much more the sound of curses. He accepts the reality of thought-transference, and of thought-transference of an extreme form, on the strength of certain experiences of his own; yet his whole interest seems to be in discountenancing inquiry into the

subject (except, perhaps, as a branch of disease) on the ground of the lax moral character of the persons through whom these results were obtained. If his mind was really "read," as he describes, then his results confirm ours; and surely that is the important point—for him, and for us, and for science. That his "subjects" may have been capable of fraud is nothing to the purpose, unless the conditions were such that fraud on their part would account for the results, which, from his account, it certainly would not do.<sup>1</sup> And, at any rate, one who has witnessed phenomena which he can describe as going far beyond ours, even if ours were genuine, might avoid "poisoning the wells" of the inquiry by mixing up thought-transference with trick-performances in dark cabinets, and attempting (by implication at any rate) to fix on persons of perfectly good repute, who voluntarily assisted us, the odium and suspicion attaching to professional "mediums," in whom "a slipperiness of moral principle" had been detected. In this connection I must also refer to a remark of Dr. Knapp's, who says: "In England, only a few people are capable of thought-transference, and are often the subject of morbid mental or moral conditions." I do not know on what evidence the latter assertion rests; there is at any rate no ground for it, in respect of any one of the "subjects" with whom we have come in contact.

Passing to Dr. Minot's remarks, I must first resist the inference which he appears to draw from the fact that in America 30,000 experiments have been made, with negative results. A large number of these trials were of a type (guessing the color of playing-cards) which there is reason to think a specially unfavorable one for the purpose, since so narrow a field of choice makes it exceptionally hard for the would-be percipient to avoid mere guessing;<sup>2</sup> while in the remaining experiments with numbers, the digits, instead of being taken in a chance order (as, for example, by drawing them from a bag), were arranged on a system—which again would be likely to have a disturbing effect on the "subject's" mind. But whether or not these conditions were answerable for the failure, no amount of mere failure elsewhere can invalidate the successes here, in experiments of very various types, involving—if the results were obtained by fraud—our own fraud, and that of other persons of otherwise unblemished character. But this point was so forcibly brought out by Dr. Prince that I need not dwell on it.

Dr. Minot is further reported to have said that "the English Society is in the condition of investigators whose tests have been rendered quite unreliable by the fact that they were themselves the dupes of their own ideas." They ask of us a tremendous act of faith, as the foundation of all further action. Now, as any stick is good enough to beat a dog, so any statement, however rash, may serve to disparage a psychological researcher. But it surely is rash to assume that we believed in thought-transference before we (as we think) found it, or that we were insensible of what we have constantly admitted and proclaimed—the strength of the *a priori* presumption against it. And if, having (as we think) found it, we are "the dupes of our own ideas" in believing in it, the function of experimentation seems rather abrogated. It is surely not a necessary condition of reliability in a novel experiment that its results shall conform to previous anticipations. As for our alleged demand for "a tremendous act of faith," I cannot conceive where Dr. Minot thinks that he has come across it. We have urged again and again that in such matters no line can be drawn at which it can be said that a scientific mind ought to be convinced; that till every scientific mind is convinced, the proof is incomplete; and that, inasmuch as it is unlikely that all the world will have the opportunity of themselves taking part in conclusive exper-

<sup>1</sup> If Mr. Higginson would be so kind as to send me the details of the experiences to which he refers, he would earn my very warm gratitude.

<sup>2</sup> It should be noted that in England 17,000 experiments where the idea to be transferred was of the suit (not the color) of the cards, gave a cumulative result which was practically conclusive as to the operation of something beyond chance. See "Phantasies of the Living," Vol. I, p. 33.

iments, and most people will have to accept the results, if at all, on the responsibility of others, it is of prime importance to spread this responsibility as widely as possible. I endorse every word of Dr. Prince's remarks as to the need of more observers; and though the number of observers are necessarily to some extent limited by the rarity of hopeful material for observation, the fact of their fewness for which they are not to blame, must none the less be recognized as a real obstacle to the speedy acceptance of their conclusions. And so long as they themselves admit this, and go on trying to remove the obstacle by urging wider and ever wider experiments, their demand is surely not so much for faith as for works.

There is one special criticism of Dr. Minot's to which I must advert, as it again exemplifies the "any stick" style of argument. He mentions the recent case of a hypnotised boy who could discern the matter of a printed page from the extremely minute reflexion of it in another person's cornea; and he adds, "such experiments were unknown to the English investigators, and their results must not be looked upon as conclusive." This remark could have no point unless it were implied that in the results attributed by us to thought-transference the mode of perception may have been the same as the hypnotised boy's. Yet a very little study of our reports would have shown (1) that in not one per cent. of our experimental cases, and, as far as I remember, not in a single case where the idea to be transferred was that of a visible object was the "subject" hypnotised; and (2) that in cases where an object was visibly presented to the agent while the attempt to transfer the idea of it was in progress (as in some of the

experiments in the reproduction of diagrams), either the percipient was blindfolded or the agent was placed behind him.

Coming to our cases of spontaneous telepathy, Dr. Minot objects to them that "the phantasms possess little in the way of diversity or novelty." The subjects all tell the same story, subject only to variations of time, place and persons. The facts are always the same. "This is to a great extent true; and the point is one which, in 'Phantasms of the Living,' I have ventured to emphasize as an argument for the substantial correctness of the majority of our first-hand records. Fictitious and anonymous tales of the 'supernatural,' and even second and third-hand narratives of the telepathic type, abound in novel and sensational details which are conspicuous by their absence from our first-hand testimony. The monotonous uniformity of this testimony—coming as it does from hundreds of independent sources, and from persons who knew nothing of the telepathic theory—though it may make the accounts dull reading, is surely not otherwise to their disadvantage.

Dr. Minot further compares our records to those relating to witchcraft, which he says were of a similar monotonous type. On this subject, I may perhaps be allowed to refer your readers to "Phantasms of the Living," (Chap. iv, where I have tried to show the need of very carefully discriminating various classes of witch-cases, and have worked out in some detail the contrast between the evidence for telepathy and that which has been adduced for various species of popular superstition.

I am, sir, yours obediently,

EDMUND GURNEY,

Hon. Sec'y of the English Society for Psychical Research.

\* A fuller discussion of this part of the subject may be found in "Phantasms of the Living," Chap. II.

#### REPORTED MORTALITY FOR THE WEEK ENDING APRIL 2, 1887.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Norhampton . . . . .	12,896	6	2	16.66	16.66	—	15.00	—

Deaths reported 2,277: under five years of age 772; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fevers) 289, acute lung diseases 309, consumption 286, diphtheria and croup 118, measles 36, scarlet fever 26, diarrheal diseases 23, typhoid fever 21, whooping-cough 17, cerebro-spinal meningitis 11, erysipelas seven, malarial fever four, purpural fever three, small-pox (New York) two. From diarrheal diseases, New York eight, Boston four, Philadelphia and Lowell two each, Brooklyn, District of Columbia, Pittsburgh, Providence, Cambridge, Fall River and Chelsea one each. From typhoid fever, Philadelphia nine, New York five, Providence two, Brooklyn, Boston, District of Columbia, Lowell and Lawrence, one each. From whooping-cough, New York seven, Philadelphia four, Brooklyn three, Richmond two, Salem one. From cerebro-spinal meningitis, Worcester three, New York two, Philadelphia, Boston, Newport, Pittsburgh, Fall River and Somerville, one each. From erysipelas, New York six, Brooklyn three.

From malarial fevers, New York and Philadelphia two each. From purpural fever, New York two, Philadelphia one.

One case of small-pox reported in Pittsburgh. In the 28 greater towns of England and Wales, with an estimated population of 9,245,000, for the week ending March 19th, the death-rate was 22.4. Deaths reported 3,977: infants under one year of age 919; measles 213, whooping-cough 112, scarlet fever 45, diarrheal diseases 35, fever 32, diphtheria 24, small-pox (Sunderland) one.

The death-rates ranged from 13.9 in Birkenhead to 33.2 in Manchester; Birmingham 22.0; Bradford 20.7; Halifax 16.5; Hull 20.1; Leeds 25.1; Leicester 20.4; Liverpool 20.6; London 20.4; Newcastle-on-Tyne 28.6; Nottingham 18.4; Sheffield 23.1. In Edinburgh 19.6; Glasgow 30.3; Dublin 29.3.

The meteorological record for the week ending April 2, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.				Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.
Saturday,	Daily Mean.	Daily Mean.	Maximum.	Minimum.	7.00 A. M.	3.00 P. M.	11.00 P. M.	Daily Mean.		7.00 A. M.	3.00 P. M.	11.00 P. M.	7.00 A. M.	3.00 P. M.	11.00 P. M.	7.00 A. M.	3.00 P. M.	11.00 P. M.	Direction, Duration, & Intensity.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 2, 1887, TO APRIL 8, 1887.

HOFF, JNO. VAN R., captain and assistant surgeon. Ordered for duty at Fort Reno, I. T. S. O. 43, Department of Missouri, April 4, 1887.

CORBUSETT, W. H., captain and assistant surgeon. Granted leave of absence for one month. S. O. 35, Department of Arizona, March 29, 1887.

BURTON, H. G., captain and assistant surgeon. Ordered to Plattsburg Barracks, N. Y., for temporary duty. S. O. 78, A. G. O., April 5, 1887.

LA GARDE, L. A., captain and assistant surgeon. Ordered for duty at Fort Assiniboine, M. T. S. O. 78, A. G. O., April 5, 1887.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING APRIL 9, 1887.

URQUHART, F. M., passed assistant surgeon. To assume charge of Cape Charles Quarantine, March 29, 1887.

NORMAN, SKATON, assistant surgeon. To report for duty at Cape Charles Quarantine, April 2, 1887.

BAILLACHE, P. H., surgeon. Detailed as chairman, Board of Examiners, to meet in Washington, April 25, 1887. April 4, 1887.

PURVIANCE, GEORGE, surgeon. Detailed as member, Board of Examiners, to meet in Washington, April 25, 1887. April 4, 1887.

GODFREY, JOHN, surgeon. Detailed as recorder, Board of Examiners, to meet in Washington, April 25, 1887. April 4, 1887.

IRWIN, FAIRFAX, passed assistant surgeon. To proceed to Baltimore, Md., on special duty, April 8, 1887.

BETTS, W. J., assistant surgeon. To proceed to Norfolk, Va., for temporary duty, April 4, 1887.

#### BOSTON DISPENSARY APPOINTMENTS.

At the April meeting of the Managers of the Boston Dispensary, Dr. Henry L. Morse was appointed Physician to the Department for Diseases of the Ear; and Drs. Henry Jackson, John A. Jeffries and Robert W. Lovett, District Physicians.

#### SOCIETY NOTICE.

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY. — The annual meeting will be held at Porter's Hotel, North Cambridge, on Wednesday, April 20, 1887, at 12 o'clock. The annual address will be delivered at 1 o'clock, P. M., by Dr. H. E. Marion, of Brighton. The Censors will meet at the same place at 11.30 A. M., of the same day, to consider applications for admission to the Massachusetts Medical Society. The general assessment should be paid to Dr. J. W. Willis, Treasurer, before the annual meeting of the State Society. Telephone number of hotel 7294. WALTER ELA, Secretary.

#### BOOKS AND PAMPHLETS RECEIVED.

The Forty-Eighth Annual Report of the Superintendent of the Boston Lunatic Hospital, to the Board of Directors for Public Institutions. For the Year ending December 31, 1886. Boston, 1887.

Sphygmography and Cardiography, Physiological and Clinical. By Alonzo T. Keyt, M.D. Edited by Asa B. Feham, M.D. and M. H. Keyt, M.D. New York and London: G. P. Putnam's Sons. 1887.

The Nursing and Care of the Nervous and Insane. By Charles K. Mills, M.D., Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic, etc. Philadelphia: J. E. Lippincott Company. 1887.

The Presbyterian Eye, Ear and Throat Charity Hospital of Baltimore City, Monthly Report. The New Treatment of Cataract Patients. By Julian J. Chisolm, M.D., Surgeon in Charge of the Hospital. 1887. (Reprint.)

Fourth Biennial Report of the Board of Trustees and Officers of the Minnesota Hospital for Insane (organized 1886). Located at St. Peter, and Second Minnesota Hospital for Insane (organized 1877). Located at Rochester, to the Governor of Minnesota for the Biennial Period ending July 31, 1886. St. Paul, 1886.

A Descriptive List of Anthropometric Apparatus, consisting of Instruments for Measuring and Testing the Chief Physiological Characteristics of the Human Body. Designed under the Direction of Mr. Francis Galton, and Manufactured and Sold by The Cambridge Scientific Instrument Company, Cambridge, England. 1887.

Cyclopedia of Obstetrics and Gynecology. The Pathology of Pregnancy, being Volume II. of a Practical Treatise on Obstetrics. By Dr. A. Charpentier. Translated under the supervision of, and with notes and additions by Egbert H. Grunlin, M.D. In Four Volumes. Forty-five fine wood engravings and two colored plates. New York: Wm. Wood & Co. 1887.

## THE CIRCULATION OF THE BLOOD IN THE ORBIT STUDIED BY MEANS OF THE PLETHYSMOGRAPH.

BY W. F. ELLIS, M.D., SPRINGFIELD, MASS.

THE vascular system of the orbit may be considered as an appendage of that of the cranial cavity. The ophthalmic artery is given off at the base of the brain, and the ophthalmic vein may be regarded as the commencement of the cavernous sinus. The circulation in the orbit is, therefore, intimately connected with that of the brain.

The circulation of the blood in the brain is subjected to peculiar conditions. The cranial cavity of the adult is inextensible, and practically filled with fluid. A certain amount of this fluid must be expressed from the cavity at the time when a new supply of blood enters it. The blood finds a sudden obstacle to its free propulsion when it passes into the cranium. This increased resistance that the blood encounters expresses itself in a very marked manner in the pulse-tracing of the brain.

Mosso<sup>1</sup> made an elaborate series of experiments with individuals who had lost portions of the skull either from accident or disease. He employed the graphic method in these investigations, and was thereby enabled to obtain permanent records of the circulation of the brain. Upon inspecting the numerous tracings published by him one is forcibly struck by the peculiar form of the pulse-curve, which is very dissimilar to that of ordinary sphygmograms obtained from peripheral arteries. In many of Mosso's experiments, the circulation of the arm was recorded at the same time as that of the brain. The arm was enclosed in a plethysmographic apparatus, which Mosso calls a hydrosphygmograph, and has been extensively employed by him in studying the local variations of the pulse.<sup>2</sup>

FIG. 1.

Figure 1, is a reproduction of a portion of one of the illustrations in Mosso's work, "The Circulation of the Blood in the Brain." The upper tracing is that of the arm obtained with the hydrosphygmograph, the lower that of the brain. The striking differences in the characters of the two tracings are very apparent. In the plethysmogram of the arm, the secondary undulations all occur in the descending portion of the pulse-curve, and the pulse is, according to Landois, anacrotic. In the brain-tracing, however, the secondary undulations, all occur in the ascending portion of the pulse-curve;

the pulse is, therefore, anacrotic. In many of Mosso's illustrations, the projecting point between the two notches in the pulse-curve of the brain occupies a higher level than the remaining portions of the curve. Mosso calls this the tricuspid form.

The apparatus employed by Mosso to record the circulatory changes within the skull was a simple one. A piece of gutta-percha was made to cover the part of the skull where there was a loss of substance. The centre of the piece was perforated with a glass-tube connected by means of rubber-tubing with a Marey's drum. The lever of the drum recorded the circulatory changes upon smoked paper covering a revolving cylinder. By means of this simple apparatus used in conjunction with the arm plethysmograph, a series of very interesting experiments were made upon the effects of different psychical conditions upon the circulation of the brain.

Several investigators have endeavored to record the intracranial circulation in animals, removing a portion of the skull of the animal experimented upon by means of the trephine. The experiments of Frédéricq<sup>3</sup> are among the latest and most successful in this direction. He obtained pulse-curves, in experimenting with dogs, quite comparable to those recorded in Mosso's experiments with the human subject.

It occurred to the writer that it would be of considerable interest to record the circulation of the orbit. The physiological importance of the subject is apparent. The circulation of the orbit is so intimately connected with that of the brain that there would seem to be great liability of circulatory changes in the larger cavity affecting the blood-supply of the smaller. If it could be proven that psychical changes affect the circulation of the orbit in the same way as they have been shown by Mosso to express themselves in the records of the circulation in the cranial cavity, then a very important advance in the means of investigating the physiology of the cranial circulation in the human subject would be made. Direct investigation of the cranial circulation can only be made in the adult upon persons who have lost portions of the skull. Such subjects are rare, and opportunities to utilize them for experimental purposes rarer. The orbit, however, is always accessible.

For the purposes of this investigation, it was necessary to have apparatus much more delicate than that employed by Mosso. The blood-supply of the orbit is brought through an artery only a millimetre in diameter. I therefore employed some forms of apparatus that I had devised for very delicate physiological work.<sup>4</sup> This apparatus is the piston-recorder for air connections, and the other piston-recorder. For the purposes of this article it is not necessary to give a minute description of this exquisitely delicate apparatus. I hope to do this in a future article, treating of the finger plethysmograph and its applicability to clinical research.

The experiments were performed as follows: A piece of gutta-percha, five millimetres in thickness, was accurately moulded to the portion of face surrounding the orbit, after previous softening in warm water. A hole was made in this in a part corresponding to the centre of the orbit. A short glass-tube was fixed hermetically to this aperture. The gutta-percha shield was securely banded over the orbit, and the glass-

<sup>1</sup> Sulla Circolazione del Sangue nel Cervello dell'Uomo.<sup>2</sup> Die Diagnostik des Pulses, Leipzig, 1879.<sup>3</sup> La Courbe plethysmographique du Cerveau du Chien, Travaux du Laboratoire, Univ. de Liège, Tome I, 1885 and 1886.<sup>4</sup> Journal of Physiology, Vol. VII, p. 309.

tube in its centre was put in communication with the piston-recorder by means of a rubber-tube. If there is no leakage of air beneath the shield, which, with proper care, may be obviated, it is easy to obtain a record upon smoked paper of the circulatory changes in the orbit. The most striking feature of these records is the peculiar shape of the pulse-curve. The curve is anacrotic, the secondary undulations appearing in the ascending portion and vertex. In order to greatly magnify these curves, I employed the ether piston instead of the ordinary form, and recorded its excursions by photography according to the method

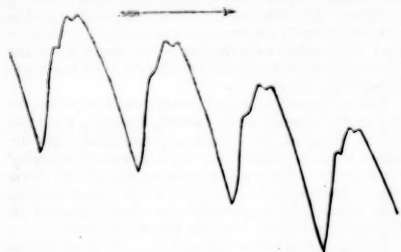

FIG. 2.

described by me in the *Journal of Physiology*.<sup>5</sup> Figure 2 is a somewhat reduced reproduction of the outline of one of the records obtained. The very marked similarity of the form of the pulse-curves in this record to that of the brain-tracing in Figure 1, is very apparent. This tracing is entirely different from one taken from the carotid in the neck or from any peripheral bloodvessel. It shows very clearly how intimately the circulation of the orbit is related to that of the cranial cavity. The peculiar form of the pulse-curve may also contribute in a measure toward the advancement of our knowledge of vascular physiology in general. The purpose of this preliminary account of these researches is to call attention to the exceeding delicacy of the methods employed, and to record the interesting fact that the pulse-curve of the orbit is very similar to that of the brain. The subject should be of interest to ophthalmologists as well as physiologists. The researches to be made with the apparatus and methods employed in these experiments will naturally tend in two directions: first, to gain, so far as possible, information of the cerebral circulation; secondly, to ascertain to what extent the condition of the circulation of the eye is indicated in the general record of the orbital tracing.

—A correspondent of the *Lancet* (March 5th) describes a case of fracture of the thigh occurring during parturition. The patient was a quintipara; the labor natural, vertex presentation, O. L. A. The birth of the head was followed very quickly by that of shoulders and body; and, as the latter came through the vulva, the attendant heard a snap, which proved to have been caused by a fracture of the patient's left thigh. The only thing noted as unusual about the case was the marked and quick rotation of the face to the right thigh after the birth of the head.

# ON A NEW METHOD OF TREATMENT OF CHRONIC-METRITIS, AND ESPECIALLY ENDO-METRITIS, BY THE INTRA-UTERINE CHEMICAL GALVANO-CAUSTIC.<sup>1</sup>

BY DR. APOSTOLI, OF PARIS, FRANCE.

INTRA-UTERINE therapeutics is asserting its claims more and more, and is justly supplanting the old exterior treatment of the cervix. The new process, which I have followed for the past four years, in the electrical treatment of fibroids, I have pursued for the same length of time, and with equal success, in curing chronic-metritis; and this same process is even better adapted to the treatment of the form generally called endo-metritis. For a lesion which, before invading the uterine parenchyma attacks first the mucous membrane, fixes itself there more or less to seize afterwards the surrounding parts, I apply a treatment wholly intra-uterine, and which will cauterize all the membrane affected. For the modern process of scraping, of liquid injections, or purely chemical intra-uterine cautery, I substitute a galvano-chemical treatment, less harsh, more concentrated, which can be localized, and which every woman can bear, if properly applied.

The immediate chemical action which consists in a progressional destruction of the mucous membrane is soon followed by a process of shrinking and disintegration which promotes the absorption of the exudation and of the hyperplasia of new formations. To be successful in this operation it is necessary to have the following electrical instruments, the function and necessary qualities of which, ought to be well understood.

*First.* A medical galvanometer divided, for intensity into milliamperes which I was the first to have graded to 200. It gives the only exact measurement of the electric force used, which before was known only in a vague and empirical way, by the enumeration of the number of cells (a cell once used never affording the same strength as a new one).

*Second.* A permanent battery of sufficient size to last for some time, and to preserve practically the same strength, after several successive operations, which will furnish with a small number of cells, thirty on an average, a high intensity of 100 to 200 milliamperes; the best battery is that of Leclanché; a good portable battery of small volume is yet to be invented, but for the present, that with bi-sulphate of mercury with facultative immersion will suffice for the requirements of the operator.

*Third.* An intra-uterine electrode of sufficient length to extend to all parts of the uterine cavity and which is not affected by acids, as platinum. It must also be provided with an isolating muff to protect the vagina, the best being a celluloid tube.

*Fourth.* A neutral or insensible electrode, which applied on the abdomen, allows a very intense current to pass without pain, without heat, and without fear of burns; the best is the one of clay, which I introduced in 1882.

*Fifth.* Cords supple enough not to obstruct, and resisting enough not to be easily broken and cause interruptions painfully felt by the patient. The physician possessing a good instrument must conform strictly to the details of the operation hereafter described.

*First.* Make a tepid and antiseptic vaginal injection.

<sup>1</sup> Translated and read before the Gynecological Society of Boston, February 10, 1887, by L. S. Fox, M.D., of Lowell, Mass.

tion, placing the patient as if for an examination by the speculum.

*Second.* Charge the battery, arrange the galvanometer and put in proper position the abdominal clay muff, and arrange the current wires.

*Third.* Introduce into the uterine cavity slowly and progressively the electrode previously singed and disinfected. Isolate entirely the vagina and vulva.

*Fourth.* Cauterize the uterine cavity thoroughly and positively in all hæmorrhagic cases, and less thoroughly in other cases.

The predominating principle in all movements is never to surprise the uterus or to make a too painful application, for it is well understood that there are irritable uteri, though of a very limited number (say from three to five per cent.) as for instance in hysterical persons, who can scarcely bear any current, however weak it may be. Such patients can receive treatment only in a very mild form. Use the current at first very slowly. Pause before extreme sensibility has been reached, in order to accustom the patient to it, and to overcome all physical and moral resistance.

After two or three applications the intensity must be increased, in most cases reaching from 100 to 150, and, if required, even 200 milliamperes. The intensity must at first be proportioned and regulated according to the patient's power of endurance; afterwards by the extent and gravity of the lesion and the time it has existed. The duration of the application, which varies from five to ten minutes must, like the intensity, be graduated according to what is expected to be accomplished. Applications should be made every week, and every second day if required; and the physician should regulate their number and frequency by the urgency of the case. A rest of at least several hours should be required of all patients who have been operated upon. This rest is necessary for the safety as well as the efficacy of the method.

Vaginal antiseptic injections of carbolic acid should be prescribed which the patient should use morning and evening. This simple and harmless treatment, truly hysterometric, is only a galvano-chemical scraping, acid or basic, according to cases; it induces a formation of new mucous membrane, and forms a kind of intra-uterine exudation, the action of which can be prolonged and varied at will. Its beneficial effect, which I have verified in a great number of instances, does not fail to make itself felt from the first, increasing rapidly and soon restoring the patient to health. It does not condemn the woman to a forced repose, and calls for no additional treatment.

#### LAPAROTOMY FOR HYDROSALPINX.<sup>1</sup>

BY F. B. HARRINGTON, M.D.

Mrs. A. B., thirty-six years of age. Married about one year, had never been pregnant. She had always been well except for slight dysmenorrhœa until she was thirty years old, when she first noticed a watery discharge coming from the vagina. This discharge, the patient thought, was connected with the menstrual flow, either immediately preceding, following or accompanying it. The amount of watery discharge was at first small, but gradually increased until on one

occasion during a period of three weeks she was obliged to use one hundred and sixty-five napkins. These napkins were used until the water began to drip from them. The amount discharged was large, although it was impossible to measure it. The amount of blood lost during menstruation, was usually small, the period not lasting more than three or four days. The watery discharges never disappeared for a longer interval than five weeks. The discharges had no odor and did not stain nor stiffen the clothing on drying. It frequently came unexpectedly, with a rush, drenching the patient. Toward the close of the discharge, it sometimes became slightly urinous in odor.

The patient was nervous, worn-out and anæmic; with a systolic hæmic murmur at the base of the heart. The urine was normal. She had, of late, severe pelvic pains on the left side, which were augmented during the discharge.

The uterus showed left lateral displacement with slight anteversion. The cervix was soft, short and thick. The body of the uterus was slightly enlarged and the cavity measured three and one-quarter inches. At the right of the uterus could be felt a fluctuating tumor, somewhat movable, filling the right side of the pelvis and pushing the uterus into the left side. Between the tumor and the abdominal wall could be felt an elongated tumor, irregular in outline, extending transversely across the pelvis toward the body of the uterus. On the left side a somewhat similar mass could be felt. The diagnosis was hydrosalpinx with a cyst probably connecting with the right tube and discharging into the uterus.

The prognosis was not favorable to recovery from the disease unless the tumors were removed. The patient gladly took the risk of an operation, for she preferred to die to the misery of her condition. On opening the abdominal cavity the right Fallopian tube was found distended to a circumference of two and three-fourths inches, connecting the uterus with an ovoid cyst three and one-half inches in the longest diameter. At the side of the cyst was another somewhat larger. Both of these cysts were covered by peritoneum. No ovary could be seen on this side.

The Fallopian tube on the left side was also dilated and at its outer extremity was the left ovary, so closely attached that they could not be separated. On this side were adhesions, old and new, to the sigmoid flexure of the colon. These masses were removed.

Examination of the tumors after removal showed those on the right of the uterus to have been made up of a cyst of the broad ligament, about three inches in diameter, and a cyst somewhat smaller resulting from the dilatation of the fimbriated extremity of the right tube. This latter cyst was connected with the remainder of the tube by a small circular opening with thickened edges. The uterine end of the tube was much less dilated than the middle portion, but the walls were greatly hypertrophied. Below the middle of the tube was a small red mass which was probably the remains of the right ovary. The left ovary and tube were intimately adherent. The former contained a number of small cysts.

Dr. Whitney, in a report of the specimens said: "The Fallopian tubes left with me show the result of chronic inflammation with retention of the secretion. The fluid which came from the left tube contained fatty degenerated epithelial cells. As to the relation of the larger cyst to the right tube, I am inclined to think

<sup>1</sup> Read before the Obstetrical Society of Boston, February 12, 1887.

that it is wholly tubal, the valve-like opening being merely a connection between the dilated and twisted tube; at any rate the lining is identical in both parts. The thin-walled cyst is probably one of the broad ligament, since the peritoneum covers it.\*

The patient soon after coming under the ether had a collapse, stopped breathing, and did not rally until she had been inverted.

The operation was completed and the patient was put to bed in fair condition, although the pulse was weak. She took nourishment and stimulants well, and there was no vomiting or pain. The temperature, however, remained slightly subnormal until the third day, when it rose to 100°. The pulse rose to 120. She was given and retained large quantities of stimulants, but she gradually became weaker and died on the third day. The loss of blood had been small, and there were no signs of septicæmia. The cause of death was collapse.

The normal secretion of the Fallopian tubes is slight and finds its way not into the uterus but into the abdominal cavity, where, being innocuous, it is absorbed and does no harm. [Schroeder.]

Closure of the uterine end, therefore, does not produce hydrops tubæ. When the peritoneal end of the tubes is closed, it allows a collection to take place and a hydrop results. Usually both ends of the tube are closed. When the uterine end of the tube is open and the distension of the tube is great, there may be periodical discharges of the fluid into the uterus; this has been called *Hydrops Tubæ Profusus*. The amount of distension of the tubes which is possible, is very great. Peaslee tapped one case and withdrew twenty pounds of fluid. Usually the greatest distension occurs at the peritoneal end of the tube.

The cause of the closure of the fimbriated extremity is either cicatricial ulceration or inflammation from within or from without the tube. The growth of a tumor may also be the cause of the closure. Often the extremity becomes attached to an ovarian tumor, and later on, this tumor may connect with the cavity of the tube.

The inflammatory causes are usually a general or local peritonitis or endometritis which extends into tubes.

Beside the above, there are certain cases of congenital closure of the tubes. Occlusion may take place anywhere along the tube or at several places, and a number of individual cysts may result.

In the majority of cases hydrops is a bilateral disease. It seems to the reader not unreasonable to suppose that some of the cases of *hydrorrhea gravidarum* and also of *hydrorrhea non-gravidarum* may be due to distended Fallopian tubes which force their contents into the uterus and vagina.

Concerning the diagnosis of hydrops tubæ, it may be said that the dilated tube has usually a sausage shape with irregular outlines, extending transversely across the pelvis. The tumor usually moves freely and distinctly from the uterus. If the distension is very great it may be impossible to distinguish it from other cystic tumors of that region. The contents may vary from a thin clear albuminous serum to a thick whitish fluid. To distinguish from a *pyosalpinx* the clinical history of the patient must be considered.

*Pyosalpinx* is usually accompanied by signs of supuration; pain, tenderness, fever and exhaustion.

Many, it might be said most, cases of *hydrosalpinx*

do not call for interference. They exist and are unknown to the patient, and their existence is not a source of great danger. They sometimes cause troublesome displacement of the uterus. Local treatment is of little use. Tapping frequently fails and is not without danger. The feeling of the writer is that, where interference is necessary, extirpation is called for both in *pyo-* and in *hydrosalpinx*.

## RECENT PROGRESS IN CARE OF THE INSANE.<sup>1</sup>

BY WALTER CHANNING, M.D.

### EXPERIENCE WITH PATIENTS IN DETACHED BUILDINGS.

UNDER this heading Dr. Dewey gives some results of the Kankakee experiment. He says they have had three detached wards with one hundred patients, in use for six years; six such wards with two hundred patients, in use for four years; and for eighteen months eighteen buildings in use with an average of over eleven hundred patients in them, though not full until June, 1886.

The expenses have not been any greater "than those of similar institutions on the 'linear' plan, nor the care of the patients presenting any greater complications. . . . And as far as the welfare of the patients occupying these buildings is concerned, their condition has been in some buildings peculiarly happy and comfortable, and in none of them have any greater discomforts and inconveniences been noticeable, than the same class of patients would encounter under any circumstances. The amount of help required averages relatively about the same as in an average congregated asylum."<sup>2</sup>

One very interesting feature of these detached buildings, is a large dining-room for four hundred male patients. These patients are the able-bodied and inoffensive class, and a large number of demented, more or less destructive and untidy, and all of them have to travel two hundred and fifty feet in the open air in all weathers to reach the dining-room. The latter arrangement is almost, or quite unique in insane hospitals.

The disadvantage of this plan is the difficulty of supervision of such a large number, especially when the weather is bad, and when the days are short and breakfast and supper are gone to in darkness.

The advantages, however, outweigh the disadvantages. The patients show a gain in health, and the attendants are obliged to look more carefully after their clothing, than would otherwise be the case. The food is also received in much better order than in ordinary ward dining-rooms.

The per capita cost of the Kankakee institution has been much less than that of most of the linear hospitals.

As a further example of the widespread tendency to provide separate buildings for different classes of the insane, the Michigan Asylum for the Insane may be mentioned.<sup>3</sup> The trustees, in their last report, state that the main asylum building is crowded, and they clearly show that simple, inexpensive buildings can be erected for a large number of the patients, in which, under proper medical supervision, they can be made comfortable, beside receiving such treatment medically as may be necessary.

<sup>1</sup> Concluded from page 354.

<sup>2</sup> Biennial Report, 1885-86. Trustees' Report.

"For want of a better term," they say, they call their plan the "colony system." It is to be regretted that they make use of the word colony, as it has been used to represent a plan of providing for the insane not sanctioned in most countries. Ghel is the prominent illustration of the colony plan, which, though well enough for Belgium, is not to be recommended for other countries. The Michigan trustees have a widely different plan in view, and it is very desirable that they should find a name for it with fewer objectionable associations.

"Their plan contemplates establishing a colony of chronic and quiet patients in some healthy farming locality, near to the institution by which it is to be managed, and from which it is to receive its patients, and derive most of its supplies. To establish this system, the institution should have, at least, six hundred acres of grass land. . . . On this tract of land colony-houses could be erected, each with a capacity of thirty beds, to be plainly, but substantially built, at an expense not to exceed \$6,000 each. . . . There should also be a cottage for the resident physician, to be placed near to, and in direct communication with all the colony houses and the asylum proper, by means of telephones, so that the business of the institution can be easily conducted at one central office. The land should be divided into farms: one for raising milk, one for making butter, one for growing stock, and one for cultivating fruit and vegetables, which will afford a variety of suitable occupation for very many male and female patients."

The general plan seems an excellent one, though it is hard to understand how a suitable building can be erected for thirty insane persons, with the proper appliances for heating, supplying water, ventilation, fire-apparatus, etc., for \$6,000, or \$200 per capita, especially if, as is stated elsewhere, the buildings are to be two miles away from the central building. This long distance will make it more difficult to connect with the general engine-house, and to reach the laundry, bakery, refrigerator building, kitchen, store-rooms, chapel, amusement hall, etc.

To make the carrying-on of the institution economical, as well as easy, all these departments should be easy of access; and the first cost of building will be much lessened if kitchen, dining-rooms, store-rooms, laundries, bath-rooms, etc., do not need to be duplicated.

However, it is to be supposed that Dr. Palmer, the experienced superintendent, and the trustees, have thought over all these points, and discovered some practical solution of them. Two buildings only are to be erected at present, each of which is not to cost over \$5,000.

Among the institutions which have already made use of detached buildings, or are now considering the question of so doing, are: the Connecticut State Hospital; Norristown, Pa., Hospital; Toledo, Ohio, Hospital; North Dakota Hospital; Wisconsin State Hospital; Athens, Ohio, Asylum; Butler Hospital, Providence, R. I.; Boston Lunatic Hospital; Oregon State Insane Asylum; Topeka, Kansas, Asylum; Government Hospital, at Washington, D. C.; Northampton, Massachusetts, State Lunatic Hospital.

#### THE COLORED INSANE.

Dr. P. Bryce\* and Dr. R. Barksdale\* refer to this

class of the insane in their last reports, and state that added buildings will be needed for their accommodation.

Dr. Bryce says: "The increase of insanity among the colored people since their emancipation has been very remarkable. The federal census, in 1850, reported in the whole United States but 638 colored insane; and in 1860, the number had increased to only 766, or say one for 5,799. Returns for 1870 show one for every 2,695, and in 1880, we find one for every 1,096. If this rate of increase is maintained, we may expect to find, in 1890, about the same proportion for both blacks and whites, which is about one for every 500 inhabitants."

Dr. Godding, of the Government Hospital, urgently asks for an appropriation to provide accommodations for the 183 colored insane persons in his institution.<sup>10</sup> He says that it is not pleasant, either to the colored or to the white patients, to be treated together.

In the annual report of the Eastern North Carolina Insane Asylum for 1886, the superintendent, Dr. Roberts, refers to the colored insane in these words: . . . "It is evident that we need increased accommodations for the colored insane. . . . While there is a vast breach between the race and the tax-paying portion of our citizens, socially, morally, politically, yet, carp as the pseudo-philanthropist may, the old slave-owner is the negro's best friend, and has for him the most genuine pity in times of affliction. Thrown on his own resources, with the cares of life and the support of his family; surrounded by temptations to indulge his passions, lusts, appetite, etc., from which he was partially, if not wholly exempt in his slavery, it is no wonder that his mental balance gives way."

In connection with the colored insane, it is interesting to know that, in the California asylums at Stockton and Napa, there are in the vicinity of 150 insane Chinamen. At Stockton, there are 67 males and 3 females. Dr. W. H. Mays, the medical superintendent, states that, in proportion to the number of Chinese in the State, insanity is particularly rife among them.<sup>11</sup>

#### CLASSIFICATION OF MENTAL DISEASES.

This subject is one always considered by all authors of works on insanity, usually with results that may be satisfactory to the individual writer, but not to readers in general.

A new interest has recently been imparted to further study in this direction by the efforts of the Society of Mental Medicine of Belgium. An International Committee to prepare a report on the subject was appointed at Antwerp, in September, 1885, which has done considerable work since that time.

Systems of classification have been prepared by Professor Verga, of Italy; Meynert, of Austria; Wille, of Switzerland; Lefebvre, of Belgium; Steernberg, of Copenhagen; D. Hack Tuke, of London; and others. All of these systems present many excellent points for adoption from a scientific point of view. Space will not permit an analysis of them here, but one of them is given for consideration. It is that of Meynert, and is as follows:

Idiocy.  
Simple Mental Disorder.  
Acute Melancholia.  
Mania.  
Insanity.  
Primary Imbecility.

\* Biennial Report, Alabama Insane Hospital, 1885-86.

\* Annual Report, Virginia Central Lunatic Asylum, 1885-86.

<sup>10</sup> Annual Report, Government Hospital for the Insane, 1886.

<sup>11</sup> Annual Report, 1886.

Chronic Primary Insanity.  
Intermittent Mental Disorder.  
Secondary Mental Disorder.  
Complicated Mental Disorder.  
Paralytic Disorder.  
Epileptical, and Hystero-Epilepsy with Brain Diseases.  
Toxic Mental Disorders.  
Alcoholic Delirium.  
Other toxic forms.  
Individuals who need watching.  
Attempts at Suicide, Crimes, etc.

This arrangement of Meynert's is probably a satisfactory one to Germans, but would not be to Americans. More especially is this the case in the present instance, as the efforts of the International Committee were to be exerted to offer a classification which might serve as a basis for international statistics of insanity, and not to represent the highest scientific point to which a system might be developed. For this purpose, the simpler the arrangement, the more practically useful it would be, and hence simplicity is apparent in nearly every system.

Clark Bell, Esq., the present President of the New York Medical-Legal Society, was the member of the International Committee for North America; and, at his request, delegates were chosen by various societies to attend a meeting called by him at Saratoga in September, 1886, to prepare a system for this country, which he could present in his report to the International Committee.

At this meeting or conference, the following points were regarded as settled: (1) That the proposed classification should be framed with special reference to its practical use, for the purpose of securing a uniform basis for international statistics. (2) That it was not deemed desirable to make a complete, detailed scientific classification of insanity, but as simple a classification as could well be framed, keeping in view American ideas on the subject of insanity.

The plan of classification finally settled on was modelled somewhat after the English one, and is as follows:

1. Mania
  - { Acute.
  - { Chronic.
  - { Recurrent.
  - { Puerperal.
2. Melancholia
  - { Acute.
  - { Chronic.
  - { Recurrent.
  - { Puerperal.
3. Primary Delusional Insanity (monomania).
4. Dementia
  - { Primary.
  - { Secondary.
  - { Senile.
  - { Organic (tumors, hemorrhages, etc.).
5. General Paralysis of the Insane.
6. Epilepsy.
7. Toxic Insanity (alcohol, morphine, etc.).
8. Congenital Mental Deficiency.
  - { Idiocy.
  - { Imbecility.
  - { Cretinism.

It was not claimed by those present at the Saratoga conference that the system was perfect, or even, perhaps, approximately perfect; but it is simple enough to be made use of by the average insane hospital superintendent, and can easily be used in tabulating hospital statistics.

As a basis to start from to establish an international standard of classification, it appears fairly satisfactory; and, in bearing a strong resemblance to the proposed English system, it possesses the advantage of making harmony of action between England and America extremely easy. These two countries may be able to unite on a system, as the first step toward a more extended international system.

## Clinical Memorandum.

### THE TREATMENT OF CHRONIC UREMIA.

BY J. B. AYER, M.D.

A PATIENT, fifty-one years of age, who died November 19, 1886, from progressive contraction of the kidneys (as shown by autopsy), was, during the last nine months, a sufferer from chronic uremia, although he performed satisfactorily the duties of an important office during the greater portion of this period.

His father died from an unknown urinary trouble, and a brother from chronic Bright's disease. There is said to be further history of kidney disease in the family.

The first symptom of nephritic disease was slight epistaxis four years ago, which was not repeated. At that time his disposition changed. He took less interest in playing with his children, and in reading to them at night. He became more reserved, went to bed early, and grew older rapidly.

The next prominent symptom was in March, 1885, when, one evening, he suddenly lost the sight of his left eye, the right eye remaining unaffected. However, he slept well, and next morning the sight was fully restored, and remained so. The third noteworthy symptom was in the fall of 1885, when he suddenly fell to the floor, losing consciousness for a moment only.

Nothing of marked importance occurred up to the period of my first attendance, February 15, 1886, and kidney disease had not been suspected. He then weighed 197 pounds; arose every morning early to take a cold bath; took long walks; slept well, and only complained of depression of spirits, of nausea, and of occasional dizziness.

There was no oedema then or subsequently. The urine was then slightly in excess of normal, and so continued up to the last month of life. All the specimens examined contained a considerable layer of albumen. Urea, which, at the first examination, was diminished to sixty-six per cent. of the normal amount, steadily decreased, until, in the last week of life, only one-quarter of the normal amount was voided. Very few casts were ever found—hyaline and granular forms. He steadily lost flesh and strength, and was constantly worrying about himself.

March 30, 1886, while at a concert, he came near losing consciousness, vomited freely, and was taken home in a half-stupid state; but he entirely recovered on his arrival home, and joked with the anxious relatives who had hastened to see him.

Last summer, there were times, after dark, when he was quite confused. Would get out of bed, and would not be able to find his way back; would, perhaps, be found on the sofa, cold and apparently lifeless. In the morning he would analyze the symptoms of the previous night, his mind being again perfectly clear.

During the fall his mind became clearer by night, but his strength rapidly diminished. He spoke of a dull pain in the occipital region, but his principal complaint was: "I feel badly all over." As soon as the duties of the day were over, he began to worry about himself. Three days before death he sank into a state of coma.

Undoubtedly the free diuresis, which continued up to the last month of life, will account for the great

preponderance of chronic uræmic symptoms over those of acute uræmia in this case. That the chief symptoms of Bright's disease, to quote Fagge, are in many cases cerebral, have been well known from an early period in its history, but there have been wide differences of opinion as to their mode of origin, which have not prevented their being called uræmic. There seems to be no doubt that uræmia is produced by the poisonous action upon the nervous centres of materials accumulated in the blood, as the result of defective excretion by the kidneys.

As Rommeleus says, "there are many theories, but one thing alone we may accept as invariable, namely, that the maladies which entail uræmic disturbances are characterized, at the time when uræmic complications break out, by the presence in the tissues of the body of an excessive amount of nitrogenous, excretory material."

We know that urea which is wholly or in part the toxic agent is derived from many sources, but principally from (a) retrograde metamorphosis of tissue (including the blood), and (b) from excess of nitrogenous food.

Attention to diet is, consequently, of prime importance in the treatment of uræmia.

An exclusive milk diet, or one made up largely of milk, is favored by the best authorities. Milk contains the right proportion of nitrogenous to non-nitrogenous food to form a perfect diet. It also has the advantage of being a good diuretic.

In our case the patient was benefited by milk diet, which he frequently took with avidity, and which, his wife noticed, had a soothing effect upon him. Unfortunately, he was frequently nauseated and made costive by it, in spite of many methods adopted, with the hope of making it more digestible and laxative.

When milk was not tolerated, other forms of liquid diet were ordered, and a certain amount of digestible meat and of farinaceous and fatty food, but as little albuminous food as possible. The theory that the loss of albumen should be made up by an extra amount of albuminous food is absurd, when we consider that the daily loss of albumen in this case did not exceed the albuminous contents of a single egg. It is a good rule not to over-feed the patient. Unless the diet is of liquid character, a large amount of pure water (Dr. Webber says fifty-two ounces daily) should be taken between meals. I could discover no advantage in Lithia water in this case. Any pure water may be taken.

Alcohol does harm, except for nausea, when a little dry champagne is indicated; or, for anorexia, when a small amount of sherry wine may be taken with food.

Diuretics proper (scopolamine, nitre, and juniper, the best of the class) were not needed in this case; but digitalis was given to "save the heart from strain," and the diuretic influence of water has been fully considered.

Diaphoresis, by keeping the bed and by warm baths, was recommended by Bright and Christison. I believe that twelve hours (at least) out of the twenty-four should be spent in bed when chronic uræmia exists. It is important to keep the temperature of the body even, and the perspiration free by wearing proper clothing; and, if patient's means allow, it will be advisable to recommend a permanent residence in a warm, dry climate. It is a fact that diseases of the kidney (except the lardaceous form) are not common

in warm climates. Pilocarpine is often useful in warding off acute uræmic symptoms.

Laxatives must generally be used when the milk diet is taken. Hunyadi water acted well with our patient. When acute cerebral symptoms threaten, clisterium may be indicated.

Sedatives. Bromides, in ten-grain doses, seemed to act well in this case in quieting the patient at night. This was important, as there was a tendency to more frequent micturition by night than during the day.

Most authors, to-day, favor the use of morphia in Bright's disease when that drug seems indicated. I have used it subcutaneously in paroxysms of renal asthma, and would not hesitate to employ it in severe neuralgia accompanying chronic uræmia, provided the patient were not an alcoholic subject. It was not indicated in the course of the case we have reported. Dr. Edes states that he has never seen a more completely favorable action of morphia, with all advantages and no disadvantages, than in excessively severe headaches in contracting kidneys.

Tonics, in our case, were not beneficial.

It seemed best to allow the patient to attend to his official duties. In this way, he obtained relief from his anxious thoughts for a few hours daily, undoubtedly prolonging life.

Finally, we can say with Bartels: "The treatment is essentially that of earlier times. So far as practice is concerned, the theoretical controversies over the nature of uræmia have proved utterly barren." And with Bright (1836): "With care, life may sometimes be prolonged many years, and without care, it is materially shortened."

## Reports of Societies.

### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. RUCKINGHAM, M.D., SECRETARY.

MARCH 14, 1887, the President, Dr. O. F. WADSWORTH, in the chair.

Dr. E. H. BRADFORD being absent, his paper, entitled

A CASE OF MCLEWEN'S OPERATION FOR RADICAL CURE OF HERNIA,

was read by Dr. E. G. CUTLER. The following is an abstract:

Various attempts have been made in the last fifteen years or more, with the help of strictly aseptic details, to cure hernia radically by ligature of the sac suture of the sac, either cutting off the sac, or rolling and twisting it into a mass, which is secured in the ring, if possible, for the purpose of acting as a plug or pad. These attempts have been, in many cases, successful; but in a number of cases relapses have occurred two or three times after the operation, and the patients, although helped, have not been cured.

Andregg, collecting one hundred and five cases of his own, watched during a period of from seven months to seven years, found relapses in thirty-nine per cent., which justifies the statement that, in a large number of instances, the benefit of the operation consists of making an uncontrollable hernia controllable. As Banks has clearly pointed out, the chief difficulty encountered is that of making the internal surface of the abdominal wall perfectly flat, for if any depression

outward remains at the inner surface of the internal ring, the omentum and intestine pressing on it will gradually force it open. It is manifestly impossible, by any suture, to sew the internal ring flat; and if that is not done, pads of sac, or suture of the external ring, though a help in many cases, are not to be depended upon in the severer cases. Even Banks, although recognizing fully the difficulty, and devising an operation of twisting the sac within the ring, and securing the twisted coil by suturing, thus preventing the untwisting, is unable, in all instances, to secure the desideratum of a flat internal surface of the abdominal wall.

McEwen's operation is so new a one, comparatively, that the Society will, perhaps, pardon the mention of it in some detail, and the report of a single case.

His aim is to pull the sac within the abdominal cavity, and place it, in a compact and wrinkled condition, on the inside of the internal ring—a pad, with the convexity pressing backwards into the abdominal cavity (under the peritoneum), around and beyond the edges of the sewn-up canal.

In brief, the details of his method are as follows: The sac is separated from the surrounding parts, and, by the help of a director or finger, freed from the outer ring, the cord, and from attachments in the canal. The finger is then passed up within the canal, and the peritoneum adjacent to the internal ring is separated by finger, detaching it from the attachment to the belly wall to an extent of half-an-inch around the inner opening of the internal ring. A needle (with a handle or needle-holder), threaded with stout catgut, knotted at the ends, is then passed through the sac, beginning at the lower end in such a way that the catgut will transfix it, as a basting-stitch or the cord in a Venetian blind. The needle is then passed through the internal ring, between the stripped-up peritoneum and the abdominal wall, and then pushed through the abdominal wall. On pulling on the catgut after the needle has been removed, the mass of sac can be pulled through the canal, and placed between the peritoneum and the internal ring. The ring should then be sewn in the usual way, except that McEwen advises passing a loop of suture through the fascias, as near the internal ring as possible; and then, after again threading with two needles, the two projecting ends of suture, to pass them through the outer edge of the incision, near the external ring. This, on tightening, will roll the parts so as to act as a flap, closing the canal.

When the hernia is congenital, the sac, after separation from the cord, is to be divided above the testicle and sewn up below, so as to form a tunica vaginalis, and above so as to form a sac, to be returned as above described.<sup>1</sup>

DR. WARREN, being called upon to open the discussion, said that he had had little experience with the radical cure of hernia, but he did not see that McEwen's operation differs much from others. In dissecting the ring, we find no particularly tough places giving support; nevertheless, the proportion of relapses occurring in the practice of experienced operators is not very encouraging. Why this should be so is not very clear. Possibly patients are not kept in bed long enough after operation. It is true that there are many cures. So there are by treatment by truss, and this is pretty surely so under twenty-one. With a recent hernia below that age, he gives an encouraging

prognosis. The truss must be put on before rising, and taken off after going to bed. Adults may recover in the same way, and quacks advertise, what is the truth, when they claim that it is done. The cures by truss in adult life are, however, the exception. One set of statistics gave two hundred cures in twenty thousand cases.

DR. CUTLER said that McEwen had now operated on hernia by his method over forty times, and had, so far, had no relapse.

#### CASES OF ORTHOPÆDIC SURGERY.

DR. BRADFORD showed, for the forcible correction of severe contraction at the knee-joint, *with* subluxation of the tibia backwards, an appliance to be used, an anæsthetic, and reported several cases of forcible under-straightening. The method is only applicable to such cases as present no bony anchylitis, but with strong fibrous adhesions. When subluxation is present, it offers a troublesome complication, for the removal of which the ordinary means of section of the ham-string tendons, followed by mechanical extension, will not entirely suffice. When the force is gradually applied in the ordinary way, in severe cases, complete correction does not take place, for the reason that the skin over the knee (where counter-pressure must come) is unable to stand the necessary pressure. A direct pulling force alone will not bring the tibia forward, if firmly adherent in the position of subluxation.

The appliance shown by Dr. Bradford was based on the principle that great momentary pressure could be applied without injury to the soft parts, as has been demonstrated by the osteoclast.

Before any attempt to straighten the limb, forward pressure for the correction of the subluxation should be made (the patient being anesthetized) by a screw-force on the calf of the leg, as near to the popliteal space as is practicable, the counter-pressure being regulated by straps over the lower end of the femur (condyles) and the lower part of the leg. It will be found that the tibia can be pushed forward without injury to the vessels or muscles. After this is done, extension of the limb can be made, the forward force on the tibia being increased, if necessary. After correction, the limb is to be placed in a fixed bandage.

DR. WARREN said that it is almost impossible to replace the bones by mere extension and bandaging. In that case some shortening remains, even if extension be made under ether.

DR. WATSON spoke of the advantage in the apparatus described by Dr. Bradford for knee-deformity over that formerly used, in which attempts were made at extension by gradually increasing the angle between a calf and a ham-splint, which motion did not tend to push the head of the tibia into place.

#### ENCYSTED PERITONITIS FROM ABSCESS OF LIVER.

DR. J. B. AYER showed the specimen, and reported the case as follows:

MR. B., forty-eight years old, has had no serious illness, but during the past fourteen years has suffered from looseness of bowels, seven or eight discharges daily, frequently of mucus character and involuntary.

He felt pain in right inguinal region February 8th, but kept himself employed at his desk till February 17th, when Dr. Ayer saw him and treated him for bronchial catarrh. As fever diminished in the course

<sup>1</sup> New York Medical Record, March 5, 1887, p. 261.

of four days, the pain in the abdomen became more marked. On the 25th, fever reappearing, he asked Dr. Warren to see him, and the following day Dr. Warren and Dr. Fitz examined him. At that time the only abnormal condition to be made out was a circumscribed pain in the region above the anterior superior spinous process. During the thirty-six hours following the examination he passed mucus, pus and blood to the extent of five ounces, and it was hoped that relief would follow.

He did seem more comfortable for a day or two, but the swelling becoming more prominent, and temperature rising, Drs. Warren and Fitz again saw him March 4th, and as there was present a circumscribed tumor as large as a fetal head in the inguinal region, advised an immediate operation. The same day the former, with the assistance of Dr. M. H. Richardson, made a transverse incision evacuating a pint of pus.

The wound did well and recovery would have followed but for double pneumonia coming on with chills March 5th, death occurring on the tenth day.

Dr. Fitz made the autopsy and found:

(a) Acute fibrinous pneumonia of left upper lobe and of right lower lobe, the former firmer and apparently more recent.

(b) The abdominal wound communicated with a circumscribed peritoneal abscess which opened into the upper part of the anterior edge of the right lobe of the liver into an hepatic abscess as large as a plum.

(c) Liver enlarged one-third, injected, presented no abnormal appearances.

(d) Rectum thickened, especially muscular coat; its mucous membrane swollen and pigmented—in general free from ulceration. Fat tissue about rectum showed occasional fibrous septa. Apparently a couple of ulcers in lower part of rectum. Nothing abnormal elsewhere.

Conclusion. Abscess of liver from chronic dysentery—the abscess causing encysted peritonitis for which an operation was necessary.

Dr. WARREN says that the case simulated typho-enteritis. There were certain features that made it not advisable to operate when he first saw the case. There was dulness, but it was not complete, and a faint resonance over the seat of pain just above the anterior superior spinous process. Three days before death there was a discharge of bile. No peritonitis followed operation, and death was due to other causes.

#### TENIA SAGINATA REMOVED BY PELLETERINE.

Dr. BUCKINGHAM showed under the microscope, the head of a *tenia saginata*. This worm, otherwise called *tenia mediocanellata*, is the worm of the cysticercus of beef, and is said to be the most difficult of the human tape-worms to expel. With this particular worm success followed only the seventh attempt, which was made with pelletterine, the previous attempts being with male fern and with pomegranate. One of the attempts with male fern, which was made by another physician was nearly successful, bringing all but the head.

In looking up such authorities as had come in his way, the speaker had become impressed with the fact that while there is strong evidence that *kameela* and *houso* are very effective in their own countries, yet turpentine and pomegranate seem to be universally well spoken of. The statement is made by Tanret

that pomegranate varies in its power according to the age of tree as well as the climate, and also with the time of year when it is gathered; also that it deteriorates with age. Pelletterine is one of the four active principles of pomegranate.

It is said to be the fact that the sulphate if given alone, is too rapidly absorbed with possibly dangerous effects, but that the tannate, which has however a bad taste, or the sulphate combined with tannic acid are safer; the dose of the sulphate being three decigrams, with the addition of tannic acid. His patient had taken it in the form put up by Tanret, but there seems to be no reason why an extemporaneous prescription should not be written. Soon after taking the medicine there was some flushing of the face and peculiar sensation in the head, with so much nausea that a cathartic, directed to be taken in half an hour, could not be taken for an hour and a quarter. It is worth while to call attention to v. Schroeder's experiments with this drug in the laboratory of Strassburg, which agree with the clinical results of many observers, that the pomegranate should be taken in one or two doses; and not as recommended in the United States Dispensatory, in small doses repeated over a considerable time. This last has the further disadvantage of unnecessarily prolonging starvation.

Dr. A. T. CABOT showed the specimens from

#### THREE CASES OF STONE IN THE BLADDER REMOVED BY LITHOLAPAXY.

CASE I. A man of about sixty was operated upon early in February. The stone weighing 110 grains and was very friable, being reduced to a fine powder by a crushing lasting only four minutes. Considerable obstruction was found in the prostate, and although there was no sign of blood during the operation it was followed by a hemorrhagic cystitis, due apparently to the sudden emptying of a bladder habitually distended. In spite of this and of the fact that a catheter had to be tied into the bladder for several days on account of complete stoppage, the case ran on a febrile course, and recovery though slow was steady.

An interesting feature in this case was that an examination of the urine previous to the operation, showed the presence of arrow-head uric acid crystals, which Ultzmann regards as evidence of stone in the pelvis of the kidney. There had been at no time any kidney symptoms in this case.

CASE II. Was that of a man seventy-seven years old, with a greatly enlarged prostate, requiring the constant use of the catheter. The stone was a soft one, and weighed eighty-six grains. Recovery was uninterrupted and quick.

CASE III. The patient was a man of seventy-six. He had a long prostate, much congested, as was shown by the amount of bleeding following the slightest instrumentation.

The stone was a hard uric acid calculus of 120 grains, and was removed February 25th.

This operation illustrated the difficulty in seizing the fragments when there is any amount of hemorrhage; for the blood collecting in the bottom of the bladder prevents the fragments from falling into this pocket where they can be easily found, and therefore makes a more protracted search for them necessary. Recovery in this case was steady and without any fever.

## RESECTION OF ELBOW.

DR. MIXTER showed sections through the joint from a case of Dr. Warren's.

DR. WARREN said that he had lately written to a number of old hospital cases in order to get permanent results. One patient operated upon in 1866, had a flail-like joint with great power in certain directions. Two operated on for ankylosis had better power, three operated on for disease had a half motion. There were four or five others.

## TUMOR OF UTERUS: LAPAROTOMY.

DR. MIXTER showed the specimen for Dr. M. H. Richardson. Growths had been going on for about a year. But one broad ligament and one ovary were seen, and puncture with a trocar showed the tumor to be solid. The tumor was transfixed by two knitting needles and a rubber-tube applied as a tourniquet before removal.

## OSTEO-SARCOMA.

DR. MIXTER showed the specimen for Dr. Beach; also several macerated specimens.

## PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. M. GREEN, M.D., SECRETARY.

FEBRUARY 12, 1887, the President, DR. WILLIAM L. RICHARDSON, in the chair.

DR. F. B. HARRINGTON reported, by invitation, a case of

LAPAROTOMY FOR HYDROSALPINX.<sup>1</sup>

## DOUBLE PYOSALPINX OF UNUSUAL SIZE.

DR. J. W. ELLIOT showed drawings of a specimen of pyosalpinx which he thought was the largest on record which had been successfully removed by laparotomy. The left Fallopian tube was dilated at a point near its outer end to the size of a cocoanut, and contained between seven and eight ounces of pus. "The right tube was nearly an inch and a half in diameter at its widest part, and doubled upon itself. Each part was some three inches in length and was adherent to its fellow. On opening the tube the canal was found to be cork-screw like, and valvular septa projected into the interior, forming sacculi corresponding with the convolutions seen from without." (Dr. Fitz). This tube contained a yellow puriform fluid and a quantity of soft, cheesy material.

The patient had been sent to Dr. Elliot for operation by Dr. Dunn. She was twenty-nine years old, and had been married one and one-half years; was healthy in her general appearance, but complained of having two tumors, one in each side, which she could easily feel. She had never had a white discharge and had never been pregnant. Her menstruation was perfectly regular, normal in amount, and without pain. She had first noticed the tumors three years ago, and they had slowly grown since that time. She suffered from partial obstruction of the bowels, which her physicians had told her was due to the pressure of the tumors. On examination, Dr. Elliot found a hard tumor on the left side about as large as a cocoanut, which he considered an ovarian cyst. On the right side the Fallopian tube was distinctly felt with its

characteristic convolutions, as large as a man's fist. Laparotomy was done on January 25th. The left tube was extensively adherent and imbedded in the broad ligament. The right tube enlarged so close to the uterus that there was no pedicle; it was necessary, therefore, to amputate it without clamp or ligature, and to take up the vessels separately. The operation was severe, lasting two and one-fourth hours. Pus escaped into the abdominal cavity, and a glass drainage-tube was accordingly placed in the abdominal wound. The patient made an excellent recovery, and was sitting up on the fourteenth day.

In reply to questions Dr. Elliot said he believed it was now well established that the best treatment of pyosalpinx was extirpation by laparotomy, and not puncture per vaginam and drainage. In regard to hydrosalpinx, the question of treatment was unsettled. Dr. Harrington's case was one of peculiar difficulty; but the question is still open whether it is not better to aspirate such tumors through the vagina. Simpson and Mundé have treated hydrosalpinx in this way with success. This does not apply, of course, to ovarian cysts.

DR. HOMANS said that the differential diagnosis between pyo- and hydrosalpinx was often difficult to make; but given a case of pyosalpinx, there was no question in his judgment but that the proper treatment was to remove the sac and its contents. These tumors are usually removable, and tapping is a slow, tedious and doubtful process, and fatal in a very large proportion of cases. He thought Dr. Elliot was fortunate in the recovery of his case, after having spilled some pus into the peritoneal cavity. A case he had seen in London, in which each tube had become a tumor twelve to fifteen inches long and two or three inches in diameter, had terminated unfavorably from the spilling of two or three drops of pus into the peritoneum during laparotomy. The operator did not drain in this case, however, as Dr. Elliot had done in the case reported.

DR. BOARDMAN agreed with the previous speakers, that extirpation was the proper treatment for pyosalpinx. No doubt the tubes had sometimes been removed unnecessarily or for insufficient reasons; but conservatism should not stand opposed to operation in proper cases. He had no belief in the common idea that the removal of the tubes unsexed a woman: patients with diseased tubes were already sterile. Being asked to define the term "unsexing," Dr. Boardman quoted Madden's definition, that the "unsexed" woman is gross in appearance, has a masculine voice, and has lost her sexual desire, this last characteristic being the one popularly associated with the term.

DR. HOMANS said that from one patient afflicted with marked nymphomania, he had removed both ovaries and tubes on account of a large fibroid tumor. The patient was glad to have the operation performed, hoping thereby to be relieved of her intense sexual desire; but the operation had no effect on this condition. Another patient, with an ovarian tumor, who had previously no sexual feeling, after ovariectomy had a boundless sexual appetite. Still another patient was in no way different in respect to her sexual feelings after removal of her ovaries from what she had been before. He thought, therefore, that the effect of removing the ovaries could not be predicted in this particular. He had never noticed any change in the voice; but such patients became stout and fat.

<sup>1</sup> See page 371 of this number of the Journal.

Regarding the operation of oöphorectomy for the relief of certain nervous symptoms, Dr. Homans said that in only one case of his own had the operation been efficacious. This was the case of a young woman who had been in an insane asylum from the age of nine, and was very violent at the menstrual epoch. She was entirely cured by oöphorectomy. In another case of insanity the patient was better for a year; but the ultimate result was not beneficial.

Dr. DAVENPORT said that within a week he had seen a patient whose ovaries had been removed two years ago, for disease and for the relief of certain nervous affections. The nervous symptoms were no better: she still had the menstrual molimen, with feelings of weight in the pelvis, and headache; she had grown stouter. She had more sexual feeling than before the operation; but intercourse was followed by prostration, and there was no orgasm.

Dr. INGALLS inquired as to the nature of the nervous symptoms for which oöphorectomy was recommended by some writers; and what reason there was to suppose that the relief from the symptoms would follow the removal of the ovaries.

Dr. HOMANS said the train of symptoms was as follows: a good deal of discomfort at the menstrual period, sometimes associated with mania; mental depression; emaciation; constant thought of the sexual organs; tenderness, either real or imaginary, over the ovaries; the uterus small or atrophied; the patient bedridden or nearly so.

Dr. HARRINGTON said that the great majority of cases of hydrosalpinx do not call for operation; but when the tumor is so large as to simulate an ovarian cyst, he believed it was better to treat it as such and remove it. These cysts often do refill, and become a source of danger from frequent tapping. The cyst in the case he had reported emptied itself; but no cure took place. When a tumor is discovered, one should try to make an accurate diagnosis; if there is doubt, it was well to puncture for diagnostic purposes.

Dr. ELLIOT said there were no constitutional symptoms to suggest pus in the case he had reported, and he thought he was to deal with an ovarian cyst. Some pathologists believe that even pyo-cysts cure themselves, as they are so seldom found at autopsies: few nephritic calculi are found at post-mortem examinations; yet surgeons find them and remove them. If pyo-cysts are neglected, they may continue to grow and cause peritonitis and pyelo-nephritis from pressure on the ureters.

The PRESIDENT inquired how the watery discharge in a case of hydrosalpinx could be distinguished from hydorrhea gravidarum.

Dr. HARRINGTON said that perhaps the fimbriated extremity of one tube has been long occluded and pregnancy has recurred through the other tube: fluid may accumulate during pregnancy in the occluded tube, and towards the end of gestation, the pressure may be sufficient to push away the membranes, and the fluid thus escape as an hydorrhea gravidarum. Or the water may escape after labor.

#### THE TREATMENT OF FISSURED NIPPLE.

Dr. BOARDMAN spoke of a case of fissured nipple, in which the application of cocaine enabled the patient to suckle without pain. The baby was in nowise affected by the cocaine.

Dr. REYNOLDS thought that all applications to fis-

sured nipples were of little value compared with mechanical protection. The desideratum was to relieve pain, and this could be best accomplished with a nipple shield. The variety of shields was great; one should be selected which could be used with comfort to the patient.

Dr. GREEN exhibited a case of obstetrical instruments and spoke of

#### THE NECESSARY ARMAMENTARIUM FOR OBSTETRIC PRACTICE.

In cities and large towns, where the proximity of the patient to the physician's home is such that any needed instrument can be sent for with only short delay, and where it is possible to promptly obtain from one of the many drug stores any desired medicine, the outfit which a physician need carry to a case of labor may be extremely simple; he needs only to be prepared to deal with the emergencies of obstetric practice without undue loss of time. In consultation practice, however, and in the country, where the obstetrician may be called to a distant patient, to deal with he knows not what complication of labor, he should go provided with an armamentarium sufficiently comprehensive to enable him to meet every possible demand upon his skill. It will be found convenient, therefore, for the accoucheur to have two obstetric bags: a small gripsack containing the comparatively few instruments and drugs which may be necessary in ordinary cases, and a larger bag, containing a complete set of instruments and appurtenances, which may be sent for when needed, or carried to cases at a distance and in consultation practice. The contents of the larger operative bag should be as follows:

1. ANTISEPTICS: nail-brush; corrosive sublimate tablets for the convenient preparation of solutions of any desired strength for disinfecting the hands and the patient's genitals, for vaginal or uterine irrigation, and for cleansing wounds or lacerations before suturing them; carbolic acid crystals, with which to make a 1:20 solution for disinfecting instruments; a small jar of oil of eucalyptus and vaseline, 1 to 8, to use as an antiseptic emollient for hands and instruments.

2. CATHETERS: a long, silver, female catheter, for emptying the bladder; a long, English gum-elastic catheter with stylet for a variety of uses, namely:—to empty the bladder, when the fetal head is low and pressing on the urethra, or when for any reason a more pliant or longer catheter is needed; to rupture the membranes high up in hydramnios or other conditions; to catheterize the uterus for the purpose of exciting contractions; to inflate the fetal lungs; to replace the prolapsed funis, after the manner described by Prof. Richardson<sup>2</sup> at a former meeting of this society.

3. SYRINGES: a Davidson syringe with rectal and vaginal nozzles, the latter to be of hard rubber, also the long, block-tin, intra-uterine tube, which can be bent to conform to the pelvic curve; it is also well to have the hard rubber spray attachment for irrigating the external genitals. A two-ounce, hard rubber syringe, although not essential, is of great utility in the administration of certain rectal enemata, which soil, and in some cases injure, the soft rubber syringe. A hypodermic syringe; in the same case may be included soluble tablets of morphine, pilocarpine, atropia, and ergotone.

<sup>2</sup> Boston Med. and Surg. Journal, Vol. cxiv, No. 11, p. 224.

4. CERVICAL DILATORS AND TAMPONS: although in most instances the fingers are the best dilators, cases do occur in which Barnes' bags are very serviceable; they should therefore be included, together with the inflating bulb. Braun's colpeurynter is also sometimes of value, both for exciting pains and consequent dilation by mechanical distention of the vagina, and for temporary use in some cases of hemorrhage.

5. MEDICINAL AGENTS: sulphuric ether, chloral hydrate, laudanum, ergot, brandy for hypodermic use, and Monsel's solution.

6. FORCEPS. While the ordinary Simpson's or Braun's forceps, which should be carried to every case of labor, is sufficient in most instances to accomplish delivery, the operative bag should contain some variety of the longer and more powerful instruments: the axis-traction forceps of Simpson, which can be used also without the axis-traction rods, serves very well in high operations, and is much less cumbersome than the long, French forceps, or the axis-traction forceps of Tarnier. The short, straight, Dublin forceps (Beatty) is sometimes of great value in occipito-posterior and mento-posterior positions, since, owing to the absence of the pelvic curve, the instrument may be allowed to rotate within the vagina, without danger of injury to the maternal soft parts.

7. EMBRYOTOMY INSTRUMENTS: For decapitation: Braun's hook and Ramsbotham, Jr.'s knife, the combined use of which possesses some advantage over the single use of either. For craniotomy: Simpson's modification of Smellie's perforating scissors or Braun's trephine with pelvic curve [while either will generally suffice, it is advantageous to have both instruments]; Braun's cranioclast and Meigs's bone forceps. The cephalotribe and crochet may well be omitted.

8. IN GENERAL: a blunt hook for instrumental extraction of the breech; a pelvimeter; a straight, blunt bistoury for incising the cervix or perineum in the rare instances in which these procedures are necessary; a sharp, straight bistoury suitable for opening the abdomen and uterus or for opening a vein; a good needle-holder, with a variety of needles, in a suitable book, for closing the uterus and abdomen after Cesarean section or for repairing the vagina and perineum; two artery or tissue forceps with sliding catch; a dressing forceps, which is also useful in pulling forward the tongue during etherization, and a box-wood gag; a stout pair of long, curved scissors, which may serve to cut the funis, to trim the tissues in repairing the perineum or to remove the uterus in a Porro operation; silk, silver wire and catgut for sutures; Harrington's salt infusion apparatus, with a few powders, and a suitable filter (absorbent cotton will answer).

9. MINOR ACCESSORIES: long, curved, uterine dressing forceps; a pair of placental forceps, for the rare instances when the fingers will not suffice; a roll of half-inch tape, for use as a fillet in extracting the breech, or a sling in podalic version; some bobbin for tying the funis; collodion; safety pins.

10. THE BAG ITSELF: with the help of an inside, hinged flap, and a pocket to hold bottles and other small articles, this armamentarium may be contained in a bag twenty inches long, twelve inches high, and six inches thick; by the aid of loops or of wooden blocks and buttons, the instruments can be kept each in its proper place and not rub or abrade their neighbors. The whole interior should be lined with chamois skin,

and thereby the instruments may be kept bright and clean, if they are nickel-plated. There is also sufficient space in such a bag for several toilet articles, should the distance of the patient detain the physician over night and render such accessories desirable.

With a complete instrumentarium within sending distance the accoucheur may go to his cases in light marching order. His skirmishing gripsack need contain only the few necessary drugs, short forceps, catheter, perineal instruments, syringes, and scissors, and the ever-necessary means for surgical cleanliness.

## BOSTON MEDICO-PSYCHOLOGICAL SOCIETY.

PHILIP COOMBS KNAPP, M.D., SECRETARY.

JANUARY 20, 1887, DR. GEORGE T. TUTTLE in the chair.

DR. J. B. AYER read a paper on

### THE TREATMENT OF CHRONIC URÆMIA.<sup>1</sup>

DR. FISHER said that he had been interested in the subject of uræmia for twenty-five years. In his early practice, he had had a patient who died with an anomalous form of delirium, and the urine found in the bladder after death was albuminous. At that time he considered the delirium uræmic. In a medico-legal case not long after, where there was a question of testamentary capacity, he testified that Bright's disease could cause mental impairment, although experts on the other side denied it. He had seen such impairment due to uræmia in his own practice, and it is now acknowledged to cause both acute and chronic mental symptoms. He spoke of a case of transient hemiplegia, followed by violent insanity, where there was albuminuria, but this latter symptom was not discovered until after recovery from the hemiplegia and the insanity.

DR. GOLDSMITH said that, at first, he had thought that renal disease was comparatively common among the insane, but he had found that the amount of albuminuria was astonishingly small. Very little renal disease was found at the autopsies, and there were very few cases where renal disease caused insanity. He had seen uræmic delirium, but he had never seen a case of insanity where the patient was in good condition except for the renal disease, which seemed due to disease of the kidney. Evidence of renal disease was not evidence of mental affection. Morphine had not been permitted in Bright's disease until recently, and even now it was allowed only by a few. He had seen a case of insanity with great excitement, where there was albuminuria. Two half-grain doses were given within thirteen hours, with better results than usual, and the patient recovered from the insanity. Liquid food seemed to him to be of advantage; a case with gastric dyspepsia took skim-milk well. All milk was constipating, but he did not know whether skim-milk differed from ordinary milk.

DR. FISHER said that, in his experience, Bright's disease was a not uncommon lesion at autopsies of insane patients, and a few cases of insanity were due to it, although not many.

DR. GOLDSMITH thought it not unlikely, *à priori*.

DR. FISHER said that, in uræmia, we probably have starvation and anæmia of the brain, which may well cause mental trouble.

DR. GOLDSMITH said that although a comparatively

<sup>1</sup> See page 374 of this number of the Journal.

large number of sane people had renal disease, that of insane people who had it was relatively small.

Dr. FISHER said that there seemed to be some relation between the two states analogous to that between insanity and cardiac disease.

Dr. BOLAND said that the evident heredity in the reader's case was curious. The son of the patient, with transient hemiplegia, mentioned by Dr. Fisher, died of Bright's disease. Milk was pretty rich in nitrogen, but whey eliminated most of the caseine, and ought, theoretically, to be a good food. Peptonized milk worked well. He mentioned a case of Bright's, apparently moribund, where there was nausea, scanty urine, and severe frontal headache. The headache was so severe that a quarter-of-a-grain of morphine was given; and, when the pain returned with greater severity, and the patient became delirious, half-a-grain more. The patient slept heavily for some hours; the pupils were contracted, but the patient improved, and is now at work, apparently well. Quantitative examinations of the sweat have shown that pilocarpine eliminates very little urea, perhaps not enough to counterbalance its dangers.

Dr. TURNBULL said that the use of morphine in Bright's disease, and the connection between Bright's disease and insanity, were important, as morphine is often used in insanity. In a case where Bright's disease had not been suspected, he had known a quarter-of-a-grain of morphine to produce disastrous results.

Dr. KNAPP had known of one case, where an unintentionally large dose of morphine was given for some time to a patient with amyloid kidney, in which the morphine might have hastened the result. Ordinarily, however, he had given morphine in renal disease in the same way that he would in other cases, and with no ill effects. One case of disease of the heart, liver, and kidneys, with great ascites and general edema, took a quarter to a half-a-grain of morphine by the mouth every night for weeks, with benefit.

Dr. TUTTLE said that the connection between Bright's disease and insanity was interesting. He had seen several insane patients, lately, who had albuminuria and casts, and the mental symptoms and the urine improved together, so that he thought there might be some connection between the two. He mentioned an obscure case, where a nurse, who had previously had pelvic cellulitis, took cold while menstruating. She had severe abdominal pain, vomiting, coma, and jaundice. There was no albuminuria or change in the size of the liver. Three doses of elaterium caused her to regain consciousness, and she recovered.

#### THE NEW YORK ACADEMY OF MEDICINE. SECTION ON PRACTICE OF MEDICINE.

STATED meeting, March 15, 1887.

Dr. C. E. BILLINGTON read a paper on

##### LOCAL TREATMENT IN DIPHTHERIA.

Both constitutional and local treatment, he said, were of vital importance in diphtheria. The first factor to be considered in this disease was the entrance into the system of a specific poison or contagium, which, in many cases, at least, seemed to act by direct local implantation upon some portion of the air-passages, and this naturally suggested the local use of an-

tiseptics. The second factor in diphtheria was inflammation. This, if preëxisting from other causes, was very apt to invite the disease. Inflammation was an essential constituent in diphtheria, and ceased only with the cessation of the disease itself. The therapeutic indications furnished by the inflammation were: (1) The treatment of catarrhal trouble. (2) The employment of the most active anti-phlogistic measures, local and general, in the hope of cutting short or modifying the course of the disease. There was also an important contraindication, namely, the avoidance of all local applications, which have the effect of causing irritation of the parts.

The third factor in diphtheria was a membranous exudation. This, he thought, was probably an invariable element, though it varied very greatly in extent and in its characteristics in different cases. Besides acting as a local obstruction, the membranes had the effect of covering up the diphtheritic poison, thus preventing whatever antiseptic measures which might be resorted to from accomplishing their purpose effectively, and permitting septic infection to go on. The presence of membranes, however, were sometimes the lesser of two evils, the greater being their premature removal whether intentional or accidental. When this occurred, the general inflammatory action and the membranous exudation were both apt to become more marked than before. Indeed, the forcible separation of the membrane might be attended with very considerable danger. The destruction of the membrane by powerful caustics or the actual cautery had been repeatedly resorted to, in the hope of substituting a simple ulcer for the diphtheritic deposit; and undoubtedly this was the true indication present in cutaneous diphtheria. But this plan was difficult or impracticable as regards the mucous membrane, and the use of such agents had now been discarded by the great majority of the profession. In severe cases of diphtheria, the sudden removal of the exudation would leave exposed a raw and irritated surface, and the sequel would almost inevitably be an increased absorption of the diphtheritic poison. The rational indications in regard to the membrane were: (1) To effect its gradual softening and thinning by the local use of non-irritating solvents; and (2) in exceptional cases, in which their prompt removal was necessary, to accomplish this by such means as would cause the least irritation possible. The true object in treating diphtheria, Dr. Billington remarked, was not so much to cure the disease as to bring the patient through it alive.

The fourth factor in the disease was the absorption of the poison, with its attendant evils. In the earlier stages of diphtheria, the condition of the throat was not distinguishable from that met with in ordinary angina. The absorption of the poison began with the exudation, and it seemed probable to him that the disease was, at first, a local one. He here referred to the series of cases reported by him in the papers which he read before the Academy in 1876 and 1880, in which the plan of local antiseptic treatment was systematically and carefully carried out. The result was that in a large number there was little or no evidence of constitutional disturbance, while the number of deaths from toxæmia was extremely small. As indicated by his experience, nature was capable of tolerating and successfully eliminating a certain amount of the poison absorbed.

The fifth factor was the emanation of poison from those affected with the disease.

The indications of local treatment were, three: (1) To subdue inflammation. (2) To effect a gradual and superficial thinning and softening of the membranes. (3) By antiseptic measures, to minimize septic absorption.

Passing on to speak of the means by which these ends were to be accomplished, Dr. Billington said that, in the first place, the frequent swallowing of water, milk, or other bland fluid had a good effect in washing the parts clean. Ice and iced beverages also had a beneficial effect upon the inflammation present. Of medicinal agents, tincture of chloride of iron and chlorate of potassium had long been regarded by many as holding the first place. When employed with glycerine, in the proportion of one to eight, the tincture of iron was very grateful to the taste, and could be given every hour, with a little water. The chlorate of potassium might be employed in the following formula:

R Potass. chlorat. gr. xii  
Glycerinæ f 5 ss  
Liquor: calcis, f 3 i ss

M Dose, a teaspoonful.

In certain cases the tincture of iron was found too irritating, and there were other agents which could be employed in its place, such as the benzoate of sodium.

Gargles were condemned by him, and the use of the syringe was regarded as more generally applicable. Any ordinary syringe holding half an ounce or an ounce would answer, and warm water holding common salt in solution was, perhaps, as good as anything else to employ with it. Still, the use of the syringe had its limitations and dangers. Great care should always be observed in such manipulations, and this method should never be practiced when any of the membranes were partially dislodged. In nasal diphtheria, the syringe had been so long in use, he said, that it was unnecessary to speak of its advantages; but here, also, it was essential to use the greatest caution. The fluid should be thrown in with sufficient force, and the injection kept up long enough, to thoroughly cleanse the passages. He thought that the physician should always use the syringe himself, and that two or three times a day was often enough for the injections. The frequency should never exceed the tolerance of the patient. Spraying, while possessing the advantages of being a gentle and unirritating method, was not of as much service in nasal diphtheria, in his opinion, as syringing.

As regards solvents for the membrane, lime-water was of no service if it was required to secure a very rapid effect; but, in general, it was of positive therapeutic value by its gradual action. A useful formula consisted of ten minims of carbolic acid to four ounces of lime-water, which might be employed every half-hour. Lactic acid, pepsin, and other similar agents had often been recommended, but their practical value as solvents had not as yet been satisfactorily demonstrated. Trypsin and papayotin, however, had been used with good results. Inhalations of vapor were often resorted to as adjuvants. As an escharotic, nitrate of silver was to be recommended, on account of its superficial action. Tincture of chloride of iron, in the proportion of two to one, and Monsell's solution, were also of service in certain cases.

Dr. A. JACONI said that nasal diphtheria was very apt to prove fatal unless local treatment was resorted

to at an early period. The treatment which he practiced consisted of repeated injections, kept up at short intervals, both day and night, and he did not think that two or three times a day was often enough to use the syringe. Lime-water, carbolic acid, and bichloride of mercury (the latter in the proportion of 1 to 10-000), were useful for this purpose. Spraying could often be alternated with the injections with advantage. It had formerly been supposed that, in order to have any effect upon bacteria, it was necessary to use very powerful agents; but later investigations had shown that this was not really the case, Koch and others having demonstrated that a solution of carbolic acid of the strength of only 1 to 1,200, while it would not destroy bacteria, was sufficient to check their activity. It was his invariable practice to have the sick room constantly filled with the vapor of either turpentine or carbolic acid, or both.

Dr. J. LEWIS SMITH said that at the present time the greater part of the profession coincided in the opinion expressed by Dr. Billington, that diphtheria is primarily a local disease; but he could not believe that this was really the fact, at least in all cases. He had met with a number of instances in which the disease had a period of incubation lasting as long as six or eight days; which certainly indicated that it was from the first a constitutional affection. At the same time he was thoroughly in accord with Dr. Billington as to the great importance of local treatment, and also agreed with him that all irritating substances should be carefully avoided in the applications made. Muriate of pilocarpine had been very highly recommended by some, and even lauded as a specific, but he regarded this agent as exceedingly dangerous, and related a case in which fatal pulmonary oedema was apparently induced by it. The nasal passages were in his experience not infrequently the seat of the primary exudation in diphtheria; but he had found that it was quite a common occurrence for the diagnosis of nasal diphtheria not to be made out until the membranes had become very extensive, while the patient was apt to die if local treatment was not resorted to at a comparatively early period. As to the medication to be applied through the nostrils, common salt, which had been recommended by Dr. Billington was, he thought, hardly antiseptic enough, and he preferred to use salicylic or boric acid. The following was a very good formula:

R Acid boracæ.	.	.	.	.	.	.	.	.	.	℥ss
Sodii borat.	.	.	.	.	.	.	.	.	.	℥ss
Sodii chlorid.	.	.	.	.	.	.	.	.	.	℥ss
Aque	.	.	.	.	.	.	.	.	.	℥ss

M

In his practice he was in the habit of making applications to the nasal passages by means of an ordinary medicine-dropper.

He thought highly of alkaline inhalations; but the amount of lime in lime-water, which was still used to a large extent, was very small. Its alkalinity and solvent action could be materially increased, however, by adding a drachm of bicarbonate of soda to each pint of lime-water. Trypsin seemed to be of considerable benefit, and it could be used in connection with the ordinary alkaline solutions. It was the duty of every physician attending a case of diphtheria in young children, Dr. Smith thought, to note at each visit whether the child was becoming hoarse at all; hoarseness being the first indication of the invasion of the larynx and trachea of the membranous exudations.

Dr. F. H. BOSWORTH said that one point of great

importance had not been referred to, namely, the fact that glandular tumors of the pharynx, offered one of the most favorable niduses possible for the lodgment of the diphtheritic poison; while if the nasal passages and fauces were entirely clear of all obstructions the individual was much more likely to escape the disease.

Dr. Billington's paper only afforded additional proof of the fact that there are no specifics for diphtheria. It was, therefore, to the faithful carrying out of the two or three indications to which he had referred that we were to look for success in the treatment of this disease. In regard to nasal injections, he thought that placing the use of the syringe in the hands of even a trained nurse involved considerable danger, and he greatly preferred to employ the spray. Delano's atomizer (which Dr. Billington had recommended in this paper), was a good instrument as long as it would work, but the trouble with it was that it was constantly getting out of order. Hence it was better to use one constructed on a different principle, and the "Magic" atomizer, which could now be obtained at any druggist's for one dollar, was as efficient as any for the throat. For the nose, Millard's atomizer, No. 5, costing \$1.25, was probably the best form of apparatus. It had a large nozzle, and by means of it fluid could be made to pass into one nostril and out of the other. Of all cumbrous and useless applications ever put into the hands of the medical profession, he thought the galvano-cautery the worst. The effect produced with it was simply that of heated platinum wire, without any electrical action whatever, and precisely the same results could be obtained by other agents which were infinitely more convenient to handle.

DR. D. BRYSON DELAVAN spoke particularly of the value of bichloride of mercury in the treatment, and expressed regret that it had not received the attention in the present discussion to which its merits entitled it. This agent had been conclusively shown to have much greater germicide power than carbolic acid, and therefore he thought it ought to be preferred to the latter. In his own hands it proved more efficient than any other remedy. While in nasal diphtheria the efficiency of the antiseptic spray was unquestionable, he thought it was a good plan to spray the nasal passages even in the pharyngeal form of the disease, as it assisted in freeing the fauces of obstructions, and also enabled the patient to breathe through the nose. He greatly preferred the spray to the use of the syringe.

The chairman, DR. E. DARWIN HUDSON, JR., stated DR. J. T. HUTTON, of Minnesota, having reported unusually good results with the topical use of lunar caustic, Dr. Billington had written for some further particulars of his method of treatment, when Dr. Hutton replied that he would be present in person and express his views when the paper was read; and it now gave him great pleasure to introduce that gentleman to the Academy.

DR. HUTTON said that while the disease was local in the pharynx he believed that he could arrest it in every instance. His statistics showed a mortality of only twelve in two hundred and nine cases, and that notwithstanding the fact in several of them he did not give continuous treatment. His experience was confined entirely to Minnesota; although he presumed the disease was essentially the same in its general characteristics everywhere. He had gone to Minnesota to practice nine years ago, but did not meet with

any diphtheria until seven years ago. In the neighborhood where he resided five families had lost twenty children, and thirteen families thirty-six children from the disease, before he moved there. The first time that he was called upon to treat diphtheria his experience was very unfortunate. When he arrived at the house, which was twenty miles from his own home, he found that three children had already died of the disease, and three others were very low with it. He was sorry to say that two of the latter also succumbed afterwards. In the next family that he visited he first made use of the plan of treatment to which he has ever since rigidly adhered. In this household no less than five children were dead from diphtheria, and three others were very low with it. All three of the latter, however, recovered under the treatment which he then instituted, and which he believed to be infallible for the first stage of diphtheria in the region of country in which he lived, however it might be elsewhere. He did not make use of it in the stage of stenosis.

The two great indications in diphtheria, he believed, were, first, to destroy the false membranes, the disease being, in his opinion, entirely local at first, and, second, to support the patient, as the disease was usually attended with marked depression of the vital powers. For destroying the membranes he employed a solution of nitrate of silver, of the strength of twenty to fifty grains to the ounce, applied by means of a camel's hair pencil, and the application (which he said was no more painful than that of syrup or water) repeated until all the membrane was completely destroyed. He had known violent cases sometimes to be controlled by a single application. Chlorate of potash was also directed to be used as a gargle, or swallowed. In carrying out the second indication an abundant supply of fresh air was a necessity, and if it could not be obtained in any other way, the patient should be taken out of doors, unless the weather was intensely cold. As the heart was liable to fail, it was desirable to have the patient as quiet as possible, with the body kept in the recumbent position and sufficiently warm. Milk, eggs, beef-extract, and alcoholic stimulus were to be given freely, and he generally employed quinine in one-grain doses about every hour. With this plan of treatment most of the cases were gotten under control within twenty-four hours, and there was no subsequent paralysis, or other disagreeable sequela. In nasal diphtheria he used a five per cent. solution of carbolic acid by means of the syringe.

DR. JOSEPH E. WINTERS said that local treatment was impracticable in cases of diphtheria limited to the throat in young children, though this was not the case when the disease affected the nose. If diphtheria were primarily local, the first object in the treatment ought to be to destroy the membranes by means of strong caustics; yet all who had taken part in the present discussion, with the exception of Dr. Hutton, had condemned their use. All, however, agreed that local treatment should be directed against the membranes; but for his part he could not see why so much stress was laid upon the membranes, as long as they were confined to the fauces. If they were removed forcibly, or by means of caustics, they would only re-form. The one thing that promotes secretion more than anything else, is heat, and it should be constantly applied, both internally and externally. Hot applications should be made early, and should be kept

up continuously. The primary indication in diphtheria, he thought, was to prevent the extension of the membrane into the larynx, and this was also accomplished by the persevering use of heat. The patient was to be kept absolutely still, and no change from the recumbent posture allowed for any purpose whatever. If heat were properly applied externally and internally he did not think it worth while to fatigue the patient with the frequent or continued use of the spray. The croup-kettle giving off the vapor of turpentine he had found very useful, and he was also in the habit of employing the remedies mentioned by Dr. Billington. In nasal diphtheria local treatment could be satisfactorily carried out if sufficient tact were used. In the treatment of swollen glands in connection with nasal diphtheria, Dr. Winters said that he could not subscribe to the use of ice, as recommended in the paper, as he believed it to be injurious by promoting the spread of the inflammation.

DR. H. D. CHAPIN said that he greatly preferred the spray to the syringe for local treatment in the throat, and spoke particularly of the liability of the use of the syringe to excite vomiting.

DR. BEVERLY ROBINSON said that he should be very much opposed to any form of douche which caused vomiting; and that he also was decidedly in favor of the spray. He did not believe, however, that the ordinary spray-producer was of any use practically. The only atomizer which he employed was that of Dr. Lefferts, and he thought that spraying with an efficient apparatus was the only thorough way of washing out the nasal cavity. The plan referred to by Dr. Smith, of using a medicine-dropper, was simply a delusion and a snare. As to Dr. Hutton's method of treating diphtheria, it was pretty nearly as old as the history of the disease itself, and the use of lunar caustic, which had formerly been employed by a large number of physicians, had long been abandoned. Cubebs, he thought, was more useful in its action upon the throat than the chlorate of potash. He had at one time supposed that it had some specific effect, but he now believed that it was simply a very efficient agent in combating the catarrhal element of diphtheria. In his opinion there was no one remedy which would cure a very toxic case of diphtheria invariably, and death would occasionally result, whatever means might be employed against the disease.

DR. ANDREW H. SMITH said that while he agreed in the main with the practice of those who had spoken in the discussion, he did not agree with the majority of those in the matter of theory. As to the nature of diphtheria, he was glad to hear it stated that the membranes do not constitute the disease, and personally he believed it was as much a constitutional affection as scarlatina, for instance, and that the membranes were not even an essential element. We were told that the membranes were precisely the same as those met with in ordinary membranous croup, and also in those cases in which patients from time to time brought up complete casts of the trachea and ramifications of the bronchi. But if this were so, the latter class of patients must be affected with chronic diphtheria; which he could not possibly believe to be the case. The membranes, therefore, were not so important as had been represented; but still there was apt to be a necrotic process going on underneath them, and the absorption of septic material rendered it necessary to resort to local treatment. Local treatment was more important in

the nose than in the throat, and as the hard-rubber syringe was apt to cause suffering and do injury, he had been in the habit of using a soft-rubber nipple, which was attached to an ordinary hand-bulb. When this was applied in one nostril, the fluid could be made to flow out from the other. It was important that the fluid employed should be of the same density as the serum of the blood, and the preparation which he preferred was a weak solution of bichloride of mercury (1 to 4,000 or 6,000) with a drachm of salt to the pint of fluid, in order to give it the required density.

DR. WM. H. THOMSON said that what he had heard this evening had shown him that there was nothing new to be learned at present concerning the treatment of diphtheria. Twenty-five years' experience had also convinced him of the advantages of local treatment. He then related a case indicating that the disease was primarily of constitutional character.

A young man whose bed-fellow was taken with diphtheria was separated from his companion and carefully watched. On the ninth day afterward he had a very severe chill, and within ten minutes afterward his physician examined his throat and nostrils, but found nothing but a little diffused redness. In an hour, however, there was extreme congestion of the fauces, with grave constitutional symptoms; but it was not until the next day that any membranes made their appearance. On the sixth day afterward all the membrane disappeared, and the temperature was found to be normal. On the evening of the seventh day, however, he had another chill. The urine was now found to be loaded with albumen, and in two days he died from cardiac paralysis. This was a case, he thought, which clearly demonstrated that diphtheria is a purely constitutional disease. His own treatment, therefore, was based on internal support, and the question which he put to himself was, What antiseptics can be given in the largest quantity? The answer, he had found, was, Those of the chlorine group. Bromine was a useful remedy locally, and there was one agent which had not been referred to to-night which was an admirable antiseptic, particularly when any necrotic process was going off. This was the persistent use of oxygen gas.

DR. ALFRED L. LOOMIS remarked that it seemed to him that Dr. Billington had arrived at the conclusion which every sensible practitioner would come to who carefully watched his cases. While in a certain proportion of cases diphtheria might be primarily a local disease, he believed that in the great majority of instances it was primarily constitutional. In former years he had seen a great deal of it, and he had travelled over pretty much all the ground that was known as regards local treatment. He had employed, first, mechanical agents, second, escharotics, and third, astrin-gents, including the nitrate of silver. The conclusion that he had at last arrived at was, that nothing but cleanliness, with local antiseptics and constitutional support, was required. There were no specifics in this disease, and it was always best to treat the case, and not the diphtheria.

— A State Board of Health has just been established in Vermont, the twenty-ninth State in the Union to be provided with such an organization.

— Dr. H. C. Wood, of Philadelphia, has been offered the chair of medicine at the Johns Hopkins University.

THE BOSTON  
Medical and Surgical Journal.

THURSDAY, APRIL 21, 1887.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

**SUBSCRIPTION TERMS:** \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 283 Washington Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES, UPHAM & COMPANY,  
283 WASHINGTON STREET, BOSTON, MASS.

THE RAG QUESTION AND PUBLIC HEALTH.

In the recent cases of small-pox among rag-workers at Huntington, Mass., to which we referred last week, neither of the victims had ever been vaccinated. One, a girl of thirteen or fourteen years old, goes often to the rag-room where her grandmother works, and even at times helps her. The old woman has a typical vaccinal scar and does not contract the disease, but the child, unprotected by any vaccination, takes the small-pox. This child had been in attendance at the public schools, contrary to the law, and yet no objection had been made to her attendance by the town authorities.

Coincidentally with these revelations of culpable negligence on the part of mill proprietors and town authorities, whereby a whole community was endangered through the infection supposed to have been brought by rags, we have a bill passed to a second reading in the lower house of the State Legislature, relaxing the precautions now by law required in such matters, and providing that an unvaccinated pupil may be allowed to attend public schools on the certificate of two reputable physicians that "it is not advisable to vaccinate such child and that no injury to the public health is likely to occur from the admission of such child to the public schools." If a child's health is not good enough to admit of his vaccination, is it good enough to warrant sending him to school unvaccinated, and can it be true, whether certified to by "reputable physicians" or not, that school attendance of unvaccinated children, exposed as they are in manufacturing towns to multiple sources of contagion, is likely to cause "no injury to the public health?"

The report to the Boston Board of Health by Dr. J. H. McCollom, City Physician, as to the recent cases in the mill of the Parsons Paper Co., at Holyoke, — which was incorrectly outlined in two of the daily papers before it was rendered, but has not been forced into publicity since — agrees substantially with the facts heretofore laid before our readers. Of the two kinds of foreign rags used in this mill, those from Germany bore the certificate of the United States in-

spector that they had undergone (sulphur) disinfection. The other kind consisted of Russian rags, sorted and packed at Königsberg, whither they were brought ungraded, and where they lay in store for months before being baled. They were sorted into nine or ten different grades and the importers averred that no case of small-pox had occurred among their workmen for years, or "was known to exist" (*sic*) in Königsberg.

The special committee of the American Public Health Association to which were referred the resolutions of the Philadelphia Board of Health regarding the importation of infected rags, reported a resolution at the meeting in December, 1885, which after considerable discussion was referred back to the same committee with enlarged numbers for further consideration. At the meeting in 1886, the committee made a report which has just been published by the association. In this report the various infectious diseases are grouped together without any special order, and with no attempt at distinction from one another, but the actual cases of reported infection are seen to be nearly all small-pox.

In this report Dr. George M. Sternberg, the well-known bacteriologist, was extensively quoted as in favor of the compulsory disinfection of *all* rags, he having said in a letter, under date of March, 1885, "my studies relating to disease-germs leave no doubt in my mind as to the possibility of the importation of the germs of cholera, malignant pustule, small-pox and yellow fever in old rags whether baled or otherwise." Another letter from the same gentleman, however, written December 22, 1886, with reference to this report of this committee and by vote published as an addendum thereto, says: "I am not by any means as positive with reference to the necessity for disinfecting all rags as I was two years ago." He goes on to say that he has had a recent opportunity to study the methods of rag collection and shipment abroad, and that he finds that the cost of land transportation is an effectual bar to removal of rags to be shipped from a port other than one near which they were gathered. The remainder of the letter, which is rather a long one, reviews the general subject, and he concludes that during an epidemic of cholera he would exclude all rags from infected ports, and disinfect by steam, before export, rags shipped from healthy ports; but that in the absence of prevailing epidemics he would not treat rags differently from other merchandise.

The forthcoming report of the State Board of Health of Massachusetts contains an inquiry into the transmission of infectious diseases through the medium of rags, by Dr. Charles F. Withington. The paper which, as we observe from advance sheets, will occupy some seventy pages of the report, after giving a description of the gathering and treatment of foreign and domestic rags from a commercial and industrial point of view, and a historical sketch of the sanitary regulations in the United States and various European countries on the trade in rags, during times of epidemic disease, proceeds to a consideration of the recorded

evidence of infection through rags, for various diseases, giving enough of the literature to establish the fact that such infection has at times occurred. The conveyance of small-pox through this channel is abundantly shown. As to cholera the author finds *no case* in which the disease was shown to have been transmitted by foreign baled rags. The three instances cited in the Report of the Cholera Epidemic of 1873, published by order of Congress, which have been claimed by the advocates of universal disinfection, as proof of transmission of the disease by rags, were caused, if through fomites at all, by *clothing* of immigrants, and there is reasonable doubt in at least one of the cases if the disease was not contracted by direct infection through persons. Other cases are given where clothing was apparently the channel of infection, notably those on the ships *Swanton* and *New York* in 1848, on both of which immigrants opened their boxes of clothing while at sea, and were at once attacked with cholera. So, too, Dr. Rayseh's cases reported to the Hague conference, resolve themselves into six in which the source of infection is definitely stated to be clothing, and three in which the only evidence against rags is that rag-pickers were the first persons in the community to be affected.

Only one case remains, and that is the somewhat noted one, at Kriegstetten, Switzerland, where the infection was ascribed to rags, brought only sixty miles out from Zurich, and of course not subjected to any of the processes which afford protection against foreign baled rags.

Four instances, all occurring in Germany and Austria-Hungary, are given of epidemics of "rag-sorter's disease" which we understand to be simply anthrax, of which rags afford a far less serious danger than the hides and wool which commonly transmit that disease in this country.

The original observations recorded in this paper bear out in general the above facts. The source of rags causing small-pox is always difficult to determine with certainty, for the reason that in most paper-mills both foreign and domestic rags are used, all are dusted in the same machines, and the sorters work alternately on them, or at least are protected from exposure to neither class.

Of the physicians who answered the inquiries made on this point, five expressed uncertainty; three said probably foreign; five foreign; and eight domestic. It is probable that the grounds upon which these replies were made were all more or less conjectural rather than demonstrable. But it seems to us that what is known of the tenacity of life of the variolous poison makes the attempt to differentiate between the culpability of foreign and domestic rags, in this one point, rather nugatory. There being confessedly in the aggregate quite a number of cases of small-pox infection through rags, it is probable, even though in the nature of the case the exact proportion cannot be traced, that some of the offending rags are domestic and a smaller proportion are foreign, less of the latter

being in use than of the former. This is not by any means to admit the same thing regarding cholera, whose transmission by rags appears to have occurred, if at all, in but one case — and that not from baled rags. The infectious principle of cholera is of such a character that it is likely to be killed by just the processes involved in the sorting and baling of foreign rags, namely, much handling, drying, etc., and especially length of time.

The inquiry of Dr. Withington revealed no instances of transference of other affections, nor of greater ill-health among rag-sorters than in other mill operatives. A series of charts are given showing the mortality for a series of years, from various infectious diseases, scarlet fever, diphtheria, measles and typhoid fever, for a group of paper manufacturing towns compared with the State at large, and for a smaller group of exclusively paper towns compared with an equal number of similarly situated towns devoted to other branches of manufacture. The curves show no preponderance of disease in either class of towns except in the case of small-pox and possibly in that of typhoid fever.

Investigations as to the requirement of vaccination showed in some cases a lamentable slackness, in this regard, among mill owners, though it should be said that the greatest laxity was found in mills outside of Massachusetts. Inquiries as to the usage of hospitals in their disposition of soiled and infected rags showed in the main a satisfactory state of things, though one or two hospitals, instead of burning such rags, merely throw them into ash barrels, where they are probably for the most part rescued by rag-pickers and so find their way to paper-mills.

In a word, the great danger to public health from rags is small-pox. The best preventive we know against this danger is vaccination, not disinfection of rags. With vaccination, other means of protection are more or less superfluous; without it they are inadequate.

#### THE ADMINISTRATION OF QUININE IN INTERMITTENT FEVER. ARE THE PHYSIOLOGICAL ACTION, AND THE THERAPEUTIC ACTION COINCIDENT?

ALL physicians are agreed as to the utility of quinine in intermittent fevers, and whatever scepticism may exist with regard to the usefulness of medicines in general, no one doubts that the alkaloids of cinchona are efficacious in malarial diseases. Nor is there much difference of opinion as to the doses required.

There is not the same unanimity as to the period when sulphate of quinine should be given in order that the utmost benefit may be derived from it. Junior practitioners are apt to experience some bewilderment on finding that for a long time three great methods of administering bark (or quinine) have prevailed; all differing somewhat in details. There is, first, the method of Torti, called the Roman method, then that of Sydenham, called the English method, and finally

that of Bretonneau, called the French method. Torti gave his cinchona bark (quinine was then unknown) immediately before the ague fit. He prescribed two or three drachms of the powder in one dose, then he let the patient rest two days, then gave for two days in succession one drachm, and after an interval of a week, half a drachm every day for a week. Sydenham administered one large dose (3iii.) of bark (which he called "febrifuge powder") after the paroxysm, and repeated the same dose every four hours, till the time of the next chill, then let the patient rest a week when he recommenced the treatment. Bretonneau and Trousseau, who lived after the discovery of quinine, began the treatment with one large dose of sulphate of quinine, which they gave immediately after the attack; this is also Briquet's method, who urged that at least fifteen hours should elapse between the giving of the dose and the ague fit which he wished to prevent.<sup>1</sup>

Dujardin-Beaumetz, in commenting on the views of these French authorities, thinks that the space of time which separates the administration of the massive doses from the onset of the chill is too long, the physiological effect will have worn off; and he recommends to give the quinine, not immediately after the ague fit, but three or four hours before. When the fever is tertian (which is the most frequent type) he would give the quinine every other day, in one dose of half a gramme to a gramme — enough in fact should be administered to prevent the expected attack. This was also substantially the method of Gubler, who gave his quinine five or six hours before the time for the chill, as it takes about that time for the physiological action of the alkaloid to attain its maximum. Sometimes he would begin the treatment the night before the looked-for return of the chill (the patient being allowed exemption from medicine on apyretic days); at bedtime he would give the patient twenty-five centigrammes in one dose, and followed it by another equal dose in an hour; the next morning another twenty-five centigramme dose would be administered, and with this entire quantity of seventy-five centigrammes, thus given in anticipation of an attack, he was generally successful in throttling the malady.

Torti, Sydenham, Bretonneau, Trousseau, and Briquet, agree in this, that the massive doses of quinine should be given a long time (at least fifteen hours) before the ague fit which they desire to prevent. Gubler and Dujardin-Beaumetz, believing that the physiological and therapeutical effects are the same, lasting at the most not more than six hours,<sup>2</sup> do not rely on one large dose administered fifteen hours or so before the chill, but prescribe several repeated doses, of a fraction of a gramme, began near the time of the anticipated fibrile crisis.

We may remark, in concluding, that American practitioners have generally adopted the method of Bre-

tonneau, Briquet, and others, whose experience has taught them that quinine proves most effective when given as near as possible to the paroxysm which has passed. Flint thinks that if the antiperiodic be given in the sweating stage, the chances of preventing the next paroxysm are greater than if the administration be delayed till after this stage. As regards doses, he says, the most effective plan is to give the remedy so as to produce evidence of cinchonism as speedily as possible. One full dose of ten to twenty grains will generally accomplish this; he prefers, however, the method of giving smaller doses — five grains to an adult, every two hours until cinchonism is produced. By this method of treatment, he affirms, in a case of quotidian type, the chances that another paroxysm will or will not occur are about even. In a case of tertian type, the chances that another will not occur preponderate.<sup>3</sup>

Bemiss<sup>4</sup> follows substantially the same line of treatment. Beginning with the sweating stage, he gives three grains of quinia every hour till eighteen grains have been taken.

Stillé endorses the same method and remarks that "the anti-febrile influence of quinia does not coincide with its physiological operations, either in time or in degree." The physiological "cinchonism," for instance, will often have passed off, when the therapeutical effects are most apparent. He considers as sufficiently disproved the theory that the antiperiodic action of quinine is due to its sedative influence upon the nervous system.<sup>5</sup>

#### THE MISSION OF A MEDICAL SOCIETY.

In an article published in this JOURNAL, June 8, 1882, attention was called to the changes which had then been only recently inaugurated in the manner of conducting the meetings of the Suffolk District Medical Society, as the local body representing the Massachusetts State Society. The change then commented upon was the division of the large and somewhat cumbersome State Society, as represented by its membership within the District of Suffolk (about 350 at that time), into smaller bodies or Sections, devoted to the various more prominent divisions of medical and surgical practice. The plan, at that time, had been recently adopted, but the result was already much greater than the most ardent advocates of the Sections could have expected.

After a period of five years, it is possible to determine the influence of the division of this District Society, and to estimate the practical advantages or disadvantages of the system of Sections. During this time the great bulk of public medical work of the members of the State Society in this District has been done in the subordinate bodies, that is, in one or another of these Sections. There are three at present

<sup>1</sup> Gubler. *Leçons de Thérapeutique*, 1880, p. 374; D. Beaumetz. *Leçons de Clin. Ther.*, t. iii, p. 781; Briquet. *Traité Thérapeutique du Cinchona*, etc., p. 590.

<sup>2</sup> Gubler. *L.c.* cit. p. 373; Dujardin-Beaumetz. *L.c.* cit.

<sup>3</sup> Flint's Practice, Third Edition, p. 822.

<sup>4</sup> Pepper's American System of Medicine, Vol. I.

<sup>5</sup> Stillé. *Therapeutics and Materia Medica*, Vol. I, page 460.

in successful operation: that for Clinical Medicine, Pathology, and Hygiene; that for Surgery; and that for Obstetrics and Gynecology. In all these bodies there has been an abundance of scientific material for discussion at each of their regular sessions; and in some of them, notably that for Clinical Medicine, extra meetings have become necessary on more than one occasion, in order to bring the papers which have been freely offered, before the Society. The system may no longer be regarded as an experiment, but has abundantly proved its usefulness, and would now be sadly missed were its career to be interrupted. The fact is surely demonstrated that the large body of physicians residing in this District can work to much greater benefit for each and all when they are able to meet in smaller bodies, each of which may be devoted to the special consideration of some definite portion of medical practice, than when the whole body of practitioners was summoned at each meeting, where only a portion might be specially interested in the proceedings. The effect of the divisions has been to afford more frequent opportunities for gathering together, and has called out, on the whole, a far greater number of the physicians to the meetings than was the rule under the old system. The various Sections have slowly advanced in favor with the members of the Society at large, until now there are probably very few who do not consider their establishment a decided advantage to the Society itself, as well as to the individual members of the Suffolk District.

One of the most valuable indications of the healthy influence which the system of Sections has exerted upon the general profession is seen in the fact that the younger members of the Society are actively engaged in valuable work, and that they are encouraged to bring the fruits of their labors before their colleagues for their mutual benefit. There is a feeling that good work is gladly accepted from any source. It is safe to say that at no former time in the history of the Suffolk District Society has there been developed so healthful an activity among all its members, and among the profession at large, as now exists, and certainly at no previous period has there been anything approaching the amount of valuable work accomplished by the Society in its divisions as Sections, or as an individual body. The Sections are now in good working order, and are fulfilling the highest mission of such an organization. There is little of idle material in their composition, and all seem to be working for the best interests of the profession, which alone should be the aim of such a society.

The officers of the various Sections, as well as those of the general Society, are devoted to their work, and their efforts have always been generously and heartily seconded by the members. The reports of the meetings are quite full, and their production is accompanied by an amount of care, and at an expense of time and energy which speaks well for the diligence and integrity of the various secretaries. One very much needed

improvement in the Sections would be the employment of a professional shorthand writer, who should relieve the secretaries of much of the mere routine work, and thus enable them to add still more to the general efficiency of the work done at the meetings. The union of the various Sections in this effort would be the means of benefit to each, and the expense would not be a matter of any considerable importance.

We have thus passed in review the main features in the short history of the Sections, with suggestions for the further improvement of their work, and a more extensive degree of usefulness from their labors. It is not to be thought that they have yet arrived at the highest attainable degree of utility; and what has been already accomplished is only an indication of the way in which we should continue to push our efforts, trusting that another five years will show even greater results than those already accomplished. With a continuance of the loyal support thus far accorded to the Sections by the profession, this will certainly be effected. There was never a time when the work of medical progress was carried on with a greater degree of enthusiasm than at present, and there never was a time when the promise for positive and valuable results was so flattering as now. We are glad to notice among other District divisions of the Massachusetts Medical Society, though, it must be confessed, in a lesser degree, the same desirable tendency to an awakened activity.

#### HOSPITAL SATURDAY AND SUNDAY ASSOCIATION OF NEW YORK.

THE eighth annual report of the Hospital Saturday and Sunday Association, which has just been published, shows that the collection of 1886 presents an increase from its various sources, both secular and religious, in almost equal proportion. The total collection for 1886 amounted to \$53,051.98, as against \$46,085.38 in 1885, and \$36,542.75 in 1884.

When the work was first organized, the offerings from the churches came almost altogether in the form of designated gifts to particular institutions having specific denominational connections, so that this class was inordinately favored above institutions of an undenominational character. Without positively refusing designated gifts, the Association has worked steadily to discourage them, as out of harmony with the broadly humanitarian spirit of the movement, and, as events have proved, with excellent success. In the collection for 1880, for example, the designated portion constituted 45 per cent. of the whole collection, and 80 per cent. of the church collections, from which source they were chiefly derived. In the last collection, on the other hand, the designated gifts to denominational institutions had fallen from 45 per cent., in 1880, to 24 per cent. of the total collection, and from 80 to 38 per cent. of the church collections—a rate of decrease, which, if maintained, will, in a few more years, see this form of donation entirely eliminated

from the collection. Attention is also directed to the gifts of ladies in the last collection, and the hope is expressed by the Association that, out of this beginning in special interest on the part of the women of New York, there may eventually result a helpful ladies' auxiliary.

As heretofore, the Episcopal church, by members of which the hospital collection was originated in this country, continues to be by far the most liberal in its contributions to the Association. These amounted, in the last collection, to \$16,378, or nearly one-third the entire sum collected from all sources. Next come the Presbyterians, with \$6,458; the Congregationalists, with \$3,520; the Israelites, with \$1,602; the Methodists, with \$1,402; the Reformed (Dutch), with \$1,262; none of the other denominations giving as much as a thousand dollars.

The Roman Catholics have never entered to any extent into this movement, and the total contribution from them is only \$168, which is specially designated to an institution under the direction of that church. From religious sources, the whole amount contributed is \$32,784.66; and from secular sources, \$20,267.32.

#### MEDICAL NOTES.

— A device has been patented in England for the combustion of sewer-gases, which is said to act perfectly.

— Dr. A. Meynot has given the Académie de Médecine 70,000 francs for the foundation of two annual prizes; one for studies on diseases of the eyes, and one on diseases of the ears.

— A Norwegian physician named Mohn, discovered after disinfecting the bedding of one of his own children who had suffered from scarlet fever, that another child who had whooping-cough and who accidentally inhaled some of the fumes of the sulphur, was suddenly cured of the disease. Acting on this suggestion, he has treated other cases of pertussis by placing the patients in a room where sulphur had been burned in the usual manner in which it is employed for disinfectant purposes. He claims that after being put to bed in such a room, the patients awake the next morning cured.

— The *New York Sun* tells a pretty story of a woman who was carrying three leeches home, in a street-car, from an apothecary's for her sick husband, when one escaped from the box and fastened upon her wrist. Piercing shrieks from the lady called the attention of the passengers to the mishap. One man, unusually bold, went to the rescue and removed the creature, but on replacing it in the box it was found that the other two had also escaped. A general panic ensued with screams and mounting of seats by the female passengers, each of whom imagined she was wearing one or both of the other two leeches. A semblance of peace was restored only

when the missing creatures were found in the matting of the car. Their spirit was broken and their functional uselessness past restoration, but the sick man for whose swollen leg they were intended, on hearing the story, laughed till the swelling went down.

#### BOSTON AND NEW ENGLAND.

— The lectures by Dr. J. S. Billings on the History of Medicine before the Harvard Medical School will be delivered at the school building on Boylston street, on the 4th, 5th, 6th, 9th, 10th, and 11th of May, at 7.30 p. m., in lecture-room C.

— *A Marine Biological Laboratory.* — A laboratory was established at Annisquam, on Cape Ann, in 1881, by the Woman's Educational Association, with the cooperation of the Boston Society of Natural History, for students in zoology and botany, and especially for such as desired to become teachers. Since then, instruction has been given to 102 students, men and women, but the instruction has been almost wholly gratuitous, and the equipment meagre.

It is desired to extend the facilities offered by this laboratory, and to place it upon a more permanent basis. At a meeting recently held, which was attended by a number of naturalists, most of them officers of the New England colleges, it was resolved to try to raise \$7,500, to pay for a location, building, and equipment, and as much more to carry on the work of such a marine biological laboratory, as is proposed, for five years. A Committee was appointed, of which Prof. Alpheus Hyatt is Chairman, and Miss Phillips, 23 Marlboro Street, Boston, is Secretary. Subscriptions may be sent to Samuel Wells, Esq., 31 Pemberton Square, Boston.

— A most important addition is to be made to the Hemenway Gymnasium, at Harvard College, through the generosity of two gentlemen, the name of one of whom is not announced, the other of whom is Mr. Henry R. A. Carey, of New York City, a special student. The latter has given the College \$25,000, to be used in erecting a swimming bath at the rear of the gymnasium. There was a brief agitation of the subject last spring. Borings were made, and water was found in abundance. Plans were drawn up, and it was hoped that the building might have been erected and in use during the winter; but funds were lacking, and the scheme had to be given up. The gift of Mr. Carey will enable the College authorities to erect a handsome, well-equipped building at once. The usefulness, and even necessity, of a swimming bath has been felt for a long time, and it will be a great addition to the present facilities for gymnasium work and exercise. There are no swimming baths connected with any college gymnasiums at present, though it is said that there are quite a number in operation in the various large cities. Dr. Sargent highly approves the idea, and has advocated it for years. Operations will be begun immediately. The following description of the contemplated building is given: It is to be about 100 feet long by 60 feet broad. It will stand immedi-

ately back of the gymnasium, between the Jefferson Physical Laboratory and the Law School. The building will be of brick, and of a style of architecture to harmonize with that of the gymnasium. A covered passage-way will connect the two buildings, in order that the students exercising in the gymnasium may take a plunge without leaving the building. Moreover, all of the 974 lockers at present in the gymnasium are to be moved into the new building, and their space used for a larger fencing-room, and for added athletic appliances. The small douche-room is to be moved into the new building, or rather, a new one will be built, which will contain improved apparatus. The entire cost of the building, including the gift of Mr. Carey, will be about \$75,000. Besides the bathing and dressing facilities referred to, the new building is to have a perfectly-equipped racquet court. It is hoped that the building will be ready for use by the beginning of the next college year.

#### NEW YORK AND NEW JERSEY.

—Columbia was not as generous to the profession with her honorary degrees, on the occasion of her recent anniversary celebration, as Harvard was; the only two medical men on whom such degrees were conferred being Helmholtz, of Berlin, and Dr. John C. Dalton, President of the College of Physicians and Surgeons, of New York.

—The new library building, which is to be erected at Yale, through the generosity of the Hon. Simeon B. Chittenden, of Brooklyn, is intended as a memorial of the only daughter of the donor, who was the first wife of Prof. W. T. Lusk, of New York. The building, which will be the first of four or five semi-detached structures around the main library of the University, to be erected as occasion requires, will contain a handsome memorial window bearing the name of Mrs. Lusk, who is said to have been born a short distance from the spot.

—On account of the steady increase of diphtheria during the past few years, a number of prominent physicians have organized a movement to a hospital, to be devoted exclusively to cases of this disease.

—At the request of President Bayles, of the Board of Health, a census of dwellings for the poor, stables, etc., has been made, which shows that below One Hundred and Thirtieth Street, there are 28,977 tenement-houses, 316 lodging-houses, 4,576 stables, 5,522 vaults, 10,164 school-sinks, and 14,369 closets.

—About four weeks ago, measles broke out in the Brooklyn Nursery, on Herkimer Street, Brooklyn; and since that time, thirty-five out of the fifty inmates have had the disease, while the number of deaths from it has reached nine. The age of the children ranges from six months to four years, and the disease is said to have been introduced into the institution by two children who were in good health at the time of admission, but who had already been exposed to the infection of measles.

—On April 11th, the corner-stone of the Townsend pavilion annex to Bellevue Hospital was laid, with appropriate ceremonies. The new building is designed especially for cases of abdominal surgery among women, and Dr. W. Gill Wylie is to be the surgeon in charge. It is generously erected as a thank-offering by Mrs. R. H. L. Townsend, of New York, in gratitude for the success attending an operation upon herself, and will be under the supervision of a committee of ladies belonging to Calvary Church. It is to be a two-story, cottage-like structure, with a frontage of seventy feet on First Avenue, and will cost about \$7,000.

—Last week, a very successful kirmess was held at Paterson, N. J., for the benefit of the Ladies' Hospital of that place, and it is believed that about three thousand dollars will be received by the institution from the proceeds.

#### PHILADELPHIA.

—The Commencement Exercises of two of the medical schools took place last week. At the Sixty-Second Annual Commencement of the Jefferson College, which was held April 5th, Prof. Holland delivered the valedictory address, and 187 students were graduated. The Alumni Oration was given by Prof. Hunter McGuire, of Richmond, Va., on the night preceding the Commencement. His subject was the "Progress and Development of Medical Science." The lecture was held in the Hospital of Jefferson Medical College; subsequent to the lecture a reception was tendered Dr. McGuire at the Bellevue Hotel by the Alumni and friends.

—The Sixth Annual Commencement of the Medical-Chirurgical College was held on the 7th inst. Prof. P. D. Keyser delivered the Valedictory Address and Prof. Dudley S. Reynolds, of Louisville, Ky., and President of the Mississippi Valley Medical Association, delivered an Alumni Oration on "Medical Teaching, Past and Present." A dinner was afterwards held at the Colonnade Hotel, at which there were 210 covers; this is believed to be the largest entertainment by a medical college ever given in this city.

—The cause of higher medical education is not allowed to languish here, and it is quite evident to those whose observation extends over several decades that students are worked harder, longer, and to more practical ends than ever before. The examinations are more carefully conducted and are more thorough year by year. An effort has been made by the State Medical Society, by appointing a Committee on the subject, to have a State Board of Examiners and Licensees established, who alone shall confer the privilege of medical practice. Unfortunately, this has met with some opposition, both open and secret, from the colleges, who consider that they have some vested rights which are imperilled. A Matriculation Board to pass upon the preliminary qualifications of the student before permitting him to register, would probably be even less acceptable to the schools, but would

greatly aid in improving the standards of medical education and practice.

—The surgical practice of the Pennsylvania Hospital, one of the oldest and most conservative of American hospitals, has been so improved by the introduction of antiseptic dressings and methods that it is believed to be impossible for a surgeon who does not use antiseptics to be elected a member of the staff.

—Dr. William Hunt, one of the prominent surgeons of the city, met with a serious injury lately. While walking across a street he was knocked down and run over by a wagon, by which he incurred fractures of the humerus and clavicle, and severe contusions. He is slowly recovering from the accident, but will be crippled for some time to come.

—Dr. W. W. Keen, of St. Mary's Hospital, has recently performed a laparotomy for gunshot-wound of the abdomen, the subject being a woman living in Vineland, N. J., not far from this city. The patient perished finally with peritonitis, which was attributed to the presence of effused blood in the peritoneal cavity, occurring prior to operation. The autopsy showed perfect union of the wounds which had been ligatured. Dr. Jos. Hearne performed the same operation upon a boy, wounded by a toy rifle, on the 15th inst., but

the liver was wounded and the hemorrhage had been profuse; the patient scarcely survived the operation.

## Correspondence.

### THOUGHT-TRANSFERENCE.

Boston, April 14, 1887.

MR. EDITOR,—I had not thought my remarks on the subject of thought-transference at the meeting of the Clinical Section of the Suffolk District Medical Society, of sufficient importance to trespass on your space by correcting a mistake in the report, but as Mr. Gurney has taken notice of them, I feel that it is only just to answer his criticism.

In connection with Dr. Royce's suggestion that telepathy might be "a persistent trait of a former less cultured condition of the mind, a rudimentary characteristic," I called attention to the fact that the phenomena of transfer of sensation, and the curious phenomena of hypnotism were produced chiefly in hysterical patients, and those whom Féré termed "*dégénérés*,"—people whose nervous development was in some way defective,—and I added that it would be of interest to know whether the subjects of telepathy belonged to the same class. The subjects of hypnotism and the subjects of telepathy are both probably few in number, but nothing could have been farther from my intention than to speak of the latter, of whom I have no personal knowledge, as "the subjects of morbid mental or moral conditions," or to class them as "weak-minded."

Yours truly,

PHILIP COOMBS KNAPP, M.D.

### REPORTED MORTALITY FOR THE WEEK ENDING APRIL 9, 1887.

Deaths reported 2,149: under five years of age 777; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fevers) 298, acute lung diseases 476, consumption 365, diphtheria and croup 112, measles 45, diarrheal diseases 41, malarial fever 24, typhoid fever 18, scarlet fever 17, cerebro-spinal meningitis 12, whooping-cough 11, puerperal fever nine, erysipelas eight, small-pox one. From malarial fevers, New Orleans eight, Brooklyn six, Baltimore five, New York four, Charleston one. From typhoid fever, New York and Pittsburgh, five each, Boston, Richmond, and Worcester two each, Baltimore and Springfield one each. From scarlet fever, New York seven, Brooklyn and Boston three each, District of Columbia, Pittsburgh, Providence, and Brockton one each. From cerebro-spinal meningitis, New York seven, Boston, Baltimore, Worcester, Fall River and Somerville one each. From whooping-cough, New York, Brooklyn, Baltimore and Richmond two each, Pittsburgh, Newport, and Charleston one each. From puerperal fever, New York and Pittsburgh three each, Brooklyn two, Springfield one. From erysipelas, New York four, Brooklyn, District of Columbia, Pittsburgh and Milwaukee one each.

In the 20 cities and greater towns of Massachusetts, with a population of 973,945 (population of the State 1,941,465), the total death-rate for the week was 21.95 against 22.22 and 23.72 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,245,000, for the week ending March 26th, the death-rate was 23.5. Deaths reported 4,155: infants under one year of age 895; acute diseases of the respiratory organs (London) 509; measles 223, whooping-cough 97, scarlet fever 46, diarrhoea 35, fever 32, diphtheria 26.

The death-rates ranged from 16.1 in Derby to 35.4 in Manchester; Birmingham 20.5; Bradford 24.6; Hull 29.4; Leeds 21.5; Liverpool 28.7; London 21.5; Newcastle-on-Tyne 21.6; Nottingham 21.2; Portsmouth 21.2; Sheffield 22.3.

In Edinburgh 24.6; Glasgow 28.5; Dublin 31.3.

The meteorological record for the week ending April 9, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.		Relative Humidity.		Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 9, 1887, TO APRIL 15, 1887.

KANE, J. Jno., captain and assistant surgeon. Resigned April 13, 1887. S. O. 85, A. G. O., April 13, 1887.

RICHARD, CHARLES, captain and assistant surgeon. Granted two months' leave of absence on surgeon's certificate of disability. S. O. 82, A. G. O., April 9, 1887.

WALKER, TRUMAN V., first lieutenant and assistant surgeon. Ordered from Fort McIntosh, Tex., to Post of San Antonio, Tex. S. O. 45, Department of Texas, April 11, 1887.

The Army Medical Board, New York City, New York, is dissolved. S. O. 82, A. G. O., April 9, 1887.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING APRIL 16, 1887.

GRIFFITHS, S. H., passed assistant surgeon. Detached from the United States Steamship "Lancaster," and waiting orders.

HIBBERT, C. T., passed assistant surgeon. Detached from duty on Iron Clads, City Point, Va., and waiting orders.

MARSTELLER, F. H., passed assistant surgeon. Ordered to duty on Iron Clads, City Point, Va., the 20th instant.

#### SOCIETY NOTICE.

NORFOLK DISTRICT MEDICAL SOCIETY. — A meeting for Scientific Improvement will be held at the hall of the Roxbury City Guard, 67 Warren Street, Roxbury, April 26, 1887, at 7.45, P.M. "The Rosalind Disaster." "Nature of the Injuries." Clement W. Sparhawk, M.D. "Head Injuries." Henry W. Broughton, M.D. "Appliances useful in such an Emergency." Harold C. Ernst, M.D. "Personal Experiences, and Lessons of the Disaster." Joseph Steadman, M.D. "Injuries to the Back, and Effect of Shock upon the Menstrual Function." E. Penabody Gerry, M.D. (To be announced). Charles R. Whitcombe, M.D. If time is insufficient for a satisfactory consideration of all the above subjects, the last one or two will be postponed to the meeting of May 10th. Members of other District Societies are cordially invited to be present.

S. ALLEN FOTTER, M.D., Secretary.

#### ERRATUM.

In the article of Dr. Channing, published last week, for the statement (p. 251), that the Columbus, Ohio, Asylum was built forty-eight years ago, read *forty-eight* years ago.

#### APPOINTMENT.

Prof. R. H. Fitz, M.D., has been appointed Visiting Physician to the Massachusetts General Hospital.

#### DEATHS.

Died in Providence, April 18th, E. T. Caswell, M.D., formerly President of the Rhode Island Medical Society and Surgeon to the Rhode Island Hospital, aged fifty-three years.

Died in Roxbury, Boston, April 16, 1887, John Sydenham Flint, M.D., M.M.S.S., aged sixty-three years.

Died in Melrose, Mass., April 18, 1887, Joshua Vincent Smith, M.D., M.M.S.S., aged forty-one years, seven months.

#### OBITUARY. ANANDABAI JOSHEE, M.D.

The news of the death of Dr. Anandabai Joshee, from phthisis, at Poona, India, February 25, 1887, has just reached us. Some notice of this remarkable woman was made in the JOURNAL last June, which its readers may remember. Dr. Joshee was a high caste Brahmin lady, the only one who has ever received a full medical education. Her life was a remarkable one. Born and brought up in a land where woman's social position is a degraded one, she was married at the age of ten. Her husband, unlike the majority of the Indian men, was a believer in the education of women, and devoted himself to instructing her not only in the ordinary branches but in many of the higher ones also. In the spring of 1883, at the age of nineteen, she started alone for America, and in the fall of that year began to attend lectures at the Woman's Medical College of Pennsylvania. She graduated in March, 1886, standing well in her class, and then came to Massachusetts to fulfil a short appointment at the New England Hospital. Her work there, however, was interrupted by ill health, which continued until she sailed for India. She had received previous to graduation an appointment as Resident Physician in the Woman's Wards of the Albert Edward Hospital, in Kolapore, India, and doubtless had before her a brilliant future, not only in the work she might do personally, but in the immense field which lay before her in ministering to the sick and suffering, and in opening the way to the elevation of her own people. She was a faithful student and a good worker, true to herself and to her religion, and we sincerely deplore her loss so early in her life of usefulness.

## CASE OF ANEURISM OF THE INNOMINATE.

TREATED FOR FOURTEEN MONTHS BY REST, DIET, PRESSURE, AND IODIDE OF POTASH, WITH SUBSEQUENT LIGATION OF THE CAROTID AND SUB-CLAVIAN ARTERIES. DEATH AND AUTOPSY.

BY GEORGE H. LYMAN, M.D.,  
Visiting Physician, Boston City Hospital.

JOHN HARRIGAN, a porter, age thirty-eight, and married, entered the City Hospital September 22, 1884. Says he was never sick until eighteen months ago when he was in the hospital for a short time with neuralgia of the head and shoulder. Never drinks to excess and there is no history of venereal disease. Not aware of any strain or injury from heavy lifting. Three weeks before entrance he first noticed a swelling near the right sterno-clavicular articulation which interfered somewhat with respiration and deglutition. Thinks it has increased within three or four days. Painful only on pressure. Right radial pulse very feeble. Has constant sharp pain in the head and shoulder extending down the arm, some dyspnoea noted.

October 9th. Complaints of vomiting and of numbness in the right arm, neuralgia less severe, no pulmonary nor laryngeal symptoms, no dysphagia and the pulse and temperature normal. The inner end of the clavicle is displaced forwards by a pulsating tumor extending from near the centre of the sternal notch to the inner third of the clavicle, and a large fingers' breadth above and below that bone, about the size of a hen's egg, with a soft bruit in the upper part. No thrill. The rise and fall of the inner end of the clavicle perfectly visible. Left pulse normal, right pulse absent. Operative interference having been declined, and the patient being intelligent and in good general physical condition, it was determined to give him the chance of pressure with absolute rest, diet, etc. The need of implicit compliance with instructions being explained, he assented at once, and it may here be said that he followed them without complaint or infringement for the ensuing fourteen months. He was directed to maintain absolute rest upon his back and with much diminished diet to begin with ten grains of iodide of potash in infusion of hops, three times daily. Upon a plaster cast of the tumor heavy sheet lead was moulded and the plates increased to one and one-half pounds.

October 19th. The patient adapts himself with little discomfort to the restraint and is much more comfortable. The iodide increased to twenty grains.

October 24th. Tumor less prominent. Weights increased one-half pound.

October 28th. Sphygmograph shows less tension. Iodide twenty-five grains.

November 7th. A small painful swelling on right of lower jaw due probably to contact with the weight, as it disappeared when they were readjusted.

November 17th. Tumor smaller. Pulsation unchanged. Diet now consists of ten ounces of steak daily and two or three pints of fluid, less than that causing restlessness and discomfort.

November 26th. Iodide increased to thirty grains.

January 1, 1885. Pulse and size of tumor less than at any time. General condition excellent. Iodide to forty grains.

January 14th. The weights have been renewed

from time to time over fresh casts of the tumor, to secure as close adaptation as possible. He is now wearing the fifth cast, weighing 3 and 3-16 pounds. Steak increased to twelve ounces.

January 17th. For the second time has slight conjunctivitis in left eye with photophobia, for which mild collyria were ordered, and two days later the right eye was similarly affected and a superficial ulcer developed at the inner edge of the left cornea with pain and photophobia. In ten days, under a solution of atropine the eyes recovered so that he could dispense with the shade.

February 28th. A sixth cast to-day shows a manifest diminution in the prominence.

March 12th. General condition good. Has now twelve ounces steak and does not exceed two pints of liquids.

April 1st. A manifest diminution in projection of tumor. Complains the past week of neuralgic pains in the back of the head where the hair has been rubbed thin. These were relieved by a bed-rest slightly elevated. Complains of vertigo which is very annoying.

April 13th. The pains and vertigo are relieved. The six months of treatment have resulted in small but undoubted gain in pulsation, size and hardness.

May 1st. The diet increased to fourteen ounces of solid food. The lower part of the tumor is nearly solid, but the upper part has changed less. A consultation was had with Drs. Gay and Bradford, with reference to the propriety of distal ligation of the carotid, but as there was some apparent and continuous gain, operation was deferred.

June 1st. Below the clavicle the pulsation could hardly be felt, above the clavicle much less and the lateral expansion also. During the summer months he was under the care of my colleagues. At one time aconite was substituted for the iodide and the solid food increased to sixteen ounces. At the end of three weeks he had an attack of indigestion, nausea, vomiting and abdominal pain, the aconite was omitted and the indisposition yielded. On resuming service, October 10th, I found his general condition good, the pulsation below the clavicle entirely gone, and that portion of the tumor solid. Above the clavicle and at the sternal extremity, the pulsation greatly diminished and the clavicle itself was no longer moved by the pulsation.

November 12th. The calipers gave a transverse diameter of two and one-eighth inches; for the sternal end upwards two inches, and an inch to the right a vertical diameter of two and one-fourth inches. Parietes more dense and resisting. Pulsation less forcible and expansive. No bruit nor thrill.

November 20th. Seems strong and was permitted to sit up and move about a little.

November 27th. The experiment of sitting up was not encouraging, as a pulsation in the upper part of the tumor and a thrill in the carotid were developed.

As portions of the tumor had now for some time become quite solid and as no farther improvement could be reasonably expected, without surgical interference by distal ligation of the carotid or sub-clavian, one or both, and to which the patient and his friends willingly assented, he was transferred to Dr. G. W. Gay's service, from the records of which the remainder of this report is completed.

At the time of the patient's transfer to the surgical side, the aneurism extended about two inches above the clavicle, and about three inches towards its outer

<sup>1</sup> Reported at the Boston Society for Medical Improvement, March 28, 1887.

end. There was a bruit, and an expansile pulsation. No pain. Little, if any, hoarseness: no trouble in swallowing or breathing. General condition good. Pulsation in right radial very weak. No numbness or coldness of right hand.

After a careful consideration of the risks of secondary hemorrhage and of shock, it was decided to tie the carotid artery and leave the subclavian for a future operation. The disturbance from the following method of tying large vessels was so slight that in future it would undoubtedly be better to tie both vessels at the same time.

On December 11, 1885, the patient was carefully etherized, no difficulty occurring with his respiration. An incision three inches long was made by Dr. Gay, over the anterior edge of the right sterno-mastoid muscle, extending to the upper edge of the tumor. He then made a careful dissection in the superior carotid triangle, down to the common carotid artery. No ligatures used, thus far, except for a small superficial vein before it was divided. The common carotid artery was laid bare for about three-fourths of an inch just beneath the omo-hyoid muscle, which was partially divided for that purpose. The vessel having been carefully isolated, was surrounded by two braided-silk antiseptic ligatures, about three-fourths of an inch apart. These were tightly tied, and the ends cut off short. The vessels were then divided mid-way between the ligatures, with scissors. The ends of the divided artery immediately retracted, so that there was from half to three-quarters of an inch separation between them. The wound was washed with carbolic solution (1-20), dusted lightly with iodoform, and a small drainage-tube (extending through the deep cervical fascia) fastened in place. The wound was then closed with silk sutures, and a dressing of iodoform and corrosive gauze applied. Good recovery from ether. The only immediate symptoms from the operation were headache on the right side, slight hoarseness, and slight coldness of the right ear. The last-named symptom remained only one day: the headache lasted only two days. On the day following the operation, the radial pulse was found to be a little stronger than before.

The wound was dressed about every second day: the drainage-tube was removed on the third day after the operation, and the sutures on the fourth. No pus was seen at any time, and the wound (including site of drainage-tube) was wholly healed eleven days after operation. The temperature did not rise above 99.9°: the pulse increased from an average of 90 to an average of 110, and subsided in about a week to the former rate.

Examination five days after the operation, showed that the aneurism had shrunk very perceptibly above the clavicle, and that the pulsation was weaker.

The right radial pulse was the same as before the operation. Patient continued very comfortable, requiring no opiates; had no further cerebral or neurotic symptoms. About eight weeks after the operation, complained of a little pain about the right shoulder and arm; he thought arm was stiffer and more numb than previously. Had slight headache once or twice. Increase in size of aneurism very noticeable. Pulse in right radial has diminished in strength for ten days past.

After another consultation of the staff and desire expressed by the friends for further operative measures, it was decided to tie the subclavian artery.

February 9th (sixty days after ligature of the com-

mon carotid), ether was again given, and Dr. Gay made an incision about three inches long, just above and parallel with the clavicle. From the middle of this incision, a second one about an inch long, was carried perpendicularly upward. Considerable difficulty was experienced in finding the subclavian, in the course of which, a large vein, deep in the neck, was cut and ligatured. One branch of the cervical plexus was also divided. The artery was finally found, lying very deeply and about an inch higher than its usual position. The vessel was tied in two places with braided silk, and then cut across between the ligatures, the ends separating by retraction, about half an inch. A smaller artery anterior to the subclavian was also tied in like manner. The difficulty in finding the subclavian was largely due to the disturbed relations of the parts, caused by the pressure of the aneurism. A drainage-tube was inserted, the wound closed with sutures and dressed with iodoform and gauze.

After the operation, the right hand was numb, and somewhat painful: no radial or ulnar pulse on that side. Hot fomentations relieved most of the pain in hand and arm. The temperature did not rise above normal. Five days after the operation, the wound had healed by first intention, except at location of the drainage-tube. The aneurism was of about the same size, but the pulsation was somewhat less than before the operation. The hand was warm, and of good color. The tube and stitches were removed eleven days after the operation. A few drops of pus were then found about the tube: none seen previously. The wound was entirely healed eighteen days after the operation.

March 9th (one month after the operation) a plaster cast of the tumor was taken, and from this was made a lead weight weighing one and a half pounds, oval in shape and slightly larger than the tumor. This was evenly padded on its under surface and kept in place over the tumor by broad straps of adhesive plaster. Six days later, the weight was increased to two pounds, and eight days after that, to two pounds and ten ounces.

May 16th, the aneurism was less prominent than it had been two months before: there was apparently less pulsation. Patient had had unlimited diet and was growing fat.

July 17th, he sat up in bed: six days later he was up with clothes on for an hour.

Comparison of two casts of the tumor; one taken March 9th, and the other June 7th (period of using lead weight), shows quite a marked diminution in the prominence of the tumor.

The patient remained in the hospital at this time, until July 31st; at which time the width of the pulsating tumor on a line with upper border of clavicle was three inches. Vertical diameter was two and a half inches. Pulsation moderately strong; walls of sac apparently pretty thick. No pain. No affection of voice or head, and no dysphagia. One hand strong in grasp as the other.

December 22, 1886, Harrigan was again admitted to Dr. Lyman's service at the hospital. For two months after leaving, he reports that he was comfortable, but about October 1st, he began to be troubled with cough and dyspnea. Not paroxysmal—orthopnea. Expectoration thin and frothy, no blood. Complaints of weakness, anorexia, and more or less constant headache. He continued to fail, suffering much from dyspnea and died apparently from exhaustion, December 30th.

Unfortunately only a partial autopsy was permitted. The following is a report of the examination:

Crucial incision made over the sterno-clavicular articulation, the inner end of the clavicle was disarticulated and raised up. The under surface, for the space of an inch and a half was worn away smooth, involving about two-thirds the thickness of the bone, cup-shaped. The inner edge of the first rib, for the space of an inch and a half, was roughened.

The aneurism extended from a point an inch and a half above the clavicle, downwards, backwards, and to the left of the vertebral column for a distance of about eight inches. The trachea and oesophagus were crowded to the left. The antero-posterior diameter of this cavity was about four inches. It was estimated that the sac, after the clot was removed, would hold between one and two pints. The clot was laminated, and was three and one-half inches thick from the top to the cavity, which was filled with black, soft, clotted blood. This cavity would hold about two ounces. The carotid artery was impervious for the space of an inch. The subclavian was pervious for three-fourths of an inch, which was all that was removed. The vertebrae were not eroded, and did not suffer from pressure. The trachea was not diminished in calibre. The carotid and subclavian arteries emerged from the sac on the posterior surface, separated, showing that the aneurism involved the innominate artery.

The above case seems worthy of record as an instance of great relief to painful symptoms, and a positive prolongation of life in a disease necessarily fatal. An aneurism of the innominate with a sac, estimated at the autopsy to be of the capacity of one or two pints, and filled by laminated fibrine to such a thickness as to have a cavity of two ounces only, is interesting in connection with the treatment of aneurismal affections in other localities. It can hardly be doubted that the treatment prolonged life and gave great relief to the sufferer—more than that could hardly be expected in such a locality, as no counter-pressure is available to prevent the expansion of the sac inwards and downwards. Whether galvanic puncture or electricity in any of its forms would have done better is problematical. On the whole, iodide of potassa, with rest, pressure, etc., seems to be as promising as anything. Its mode of action is very uncertain. One would suppose that an excess of alkalinity would be far from desirable, but the assertion of Balfour, that no internal remedy holds out such prospect of relief, is quite in accord with the opinion of many of the best observers. He attributes its effect to its sedative action on the heart, combined with some specific effect upon the fibrous tissues, "by which the contraction of the sac is aided and its walls strengthened and condensed."<sup>2</sup>

#### OVER-DISTENSION OF THE RIGHT VENTRICLE, WITH A REPORT OF SIX CASES TREATED BY LEECHES.<sup>1</sup>

BY F. C. SHATTUCK, M.D.,  
Visiting Physician, Massachusetts General Hospital.

AN indispensable factor in efficient cardiac action is that each chamber of the heart should be able to propel onward all the blood which is delivered to it from behind, a proper balance of the circulation thus being

maintained. The tendency of any block to the circulation of the blood, no matter what its cause, is to an over-accumulation of blood in the venous, a deficiency in the arterial system; and this tendency is, of course, more or less remote, according to the proximity of the block to the starting point of the systemic arterial circulation. Thus degenerative changes in the arterial walls, and lesions at the aortic orifice do not affect the lungs, the right heart, and the veins behind, as long as increased power in the left ventricle balances the increased work which it has to perform. If the left ventricle cannot respond to the heightened demands, or has lost the capacity for doing so which it possessed for a time, the mitral valve gives way, and we get, secondarily, much the same condition of things which we find, primarily, when the seat of the original block was at the mitral or tricuspid orifices, or in the lungs. The compensatory power of the left auricle is trifling; in the pulmonary circuit there is none, and the right ventricle is, therefore, the first and only chamber which can afford any real help. With primary and non-progressive lesions at the mitral orifice, the right ventricle is very often able fully to meet the extra demands upon it; and the individual may be quite unaware that he has any pathological anatomy about him for a few years, for many years, or for the course of his natural existence, death finally resulting from causes in no special way connected with his heart lesion or from old age.

Let us, however, suppose, as we see so often occur in practice, that the right ventricle fails in a case, let us say, of mitral stenosis: as a result, we have, first, pulmonary congestion, with, perhaps, oedema, and then increasing stasis in the whole venous circulation, systemic and portal alike. The urine diminishes in quantity, and acquires the other characteristics of passive congestion of the kidneys; the liver swells and extends below the ribs; the gastric and intestinal mucous membrane is congested, and digestion is impaired to a greater or less degree; serous transudation takes place into the subcutaneous cellular tissue, and into the great serous sacs of the pleura and peritoneum, more rarely into the pericardium; cyanosis shows the surcharge of the blood with carbonic acid and other excrementitious matters.

As the distension of the right ventricle increases, the tricuspid valve becomes incompetent from dilatation of its ring of insertion; and we then have, in addition to the other evidences of venous stasis before enumerated, they, at the same time, perhaps, reaching a higher degree, a systolic reflux of blood through the right auricle into the caval and tributary veins, as far as their valves. The liver then pulsates synchronously with the heart, and the jugulars are distended, their valves standing out prominently, or even pulsate, according to the seat of the valves, and whether they remain sufficient or not. To complete the picture of a high degree of over-distension and incompetency of the right ventricle, gradual in onset, we have only to allude to the dyspnoea, the lividity, the frequent somnolency from carbonic-acid poisoning, the coldness of the extremities, the nose and ears, and to the feebleness of the pulse, which is often also irregular and intermittent. One source of danger must also be alluded to, though its existence must usually be a matter of inference, rather than of direct observation: I refer to thrombosis of the auricles and their appendages, especially of the right, whence arterial emboli may be derived.

<sup>1</sup> Read before the Boston Society for Medical Improvement, March 28, 1887.

<sup>2</sup> Edinburgh Medical Journal, July, 1868.

The above-sketched state of things is not compatible with long or comfortable existence. In most cases it is impossible to remove the cause, and thus bring about permanent relief. The cause lies in structural changes, generally of the valves of the heart, which cannot be made good. Our efforts must, consequently, be directed toward establishing or restoring the compensation, that is to say, toward enabling the right ventricle to meet the demands upon it. This is to be done by either stimulating its power, or by lessening the demands, or by both at once. In the earlier and milder grades of muscular incompetency, when the congestion of the portal system is absent or slight and digestion remains good, stimulation by heart tonics, combined with some moderation in the demand for heart power — rest and diet, with, perhaps, purgation — work to a charm. A proper balance of the circulation is struck anew, and everything goes on well again for a longer or shorter time. In the higher grades of the condition, however, when portal congestion is great and the digestion much impaired, the usual means of stimulating the ventricular contractions fail us, partly by reason of impaired absorption, partly of sluggishness of the nervous centres, partly of feebleness of the muscular wall. Under these circumstances, mechanical relief is what is wanted, what is imperative. If a portion of the load can be lifted from the right ventricle, it may be able to recover itself; otherwise, not. The withdrawal of fluid from the pleura or peritoneum is an indirect means of lifting a portion of the load, too indirect for extreme cases. The serum is outside of the circulation, and its withdrawal aids the circulation only by permitting greater functional activity of the abdominal organs or of the lungs, or by allowing serous transudation anew, and thus diminishing the mass of the blood in the veins. Free catharsis is another means, less indirect than aspiration, as the serum is derived immediately from the blood in the portal system. But it may be difficult to produce catharsis, on account of the failure of the gastric mucous membrane to absorb. We may wish, moreover, to avoid the fatigue incident to copious intestinal discharges, even when well managed. Direct means of lifting a portion of the load remains to us: the withdrawal of blood itself, either by venesection or by leeches. Much has been said and written of late years about the advantages of blood-letting in certain cases, but I do not think that we have yet reached, though we are approaching, the proper mid-position between the indiscriminate bleeding of sixty years ago, and the horror of bleeding which naturally succeeded.

There can be no question that, since the practice fell into desuetude, lives have been lost, and suffering has been endured, which might have been spared had blood been drawn. In the class of cases which I am considering the amount does not need to be large, as a rule. It is surprising how much relief follows the abstraction of as little as eight ounces, the right ventricle immediately recognizing the lessened demand, and the heart, as a whole, then responding to the stimulus of a cardiac tonic. The relief to the right ventricle allows improved circulation, and the nervous centres are in better condition to react to the drug which the stomach will now absorb. Active purgation is also often now desirable.

The choice as between blood-letting by venesection or leeching may be, but is not generally, vital. The

former is quicker, and, if it is desired to take a considerable quantity, then much preferable. But if eight or ten ounces are sufficient, a dozen leeches and a little poulticing will do the work, and there is less prejudice to overcome on the part of the patient and the friends. During the past year, I have employed or advised leeching in six cases of over-distended right ventricle, five in hospital, and one in private practice. These cases I will now report as briefly as possible, neglecting all features which do not have a direct bearing on the matter in hand.

CASE I. D., twenty-one years of age entered the Massachusetts General Hospital June 1, 1886 for mitral stenosis and regurgitation with ruptured compensation. Under rest and digitalis he improved at first; but became worse again, and July 1st, when I first saw him, he was suffering from orthopnea, vomiting, extreme cyanosis, cough, pain in the chest, ascites and anasarca. Jugular pulsation was well marked, the pulse was very irregular and intermittent, the temperature was sub-normal, and his condition was one of great gravity. The next day he was worse, and I ordered twelve leeches applied over the liver to be followed by tinct. *strophanthus* m.v. t.i.d.

July 3d, the record states: The leeches took hold well and the bites bled for two hours after the animals fell off. Within two hours the patient was much relieved, the cyanosis was much less, the radial pulse and the heart-beat were synchronous, which they had not been before. The vomiting had ceased entirely, the temperature was normal.

July 4th. The *strophanthus* was omitted, as the pulse had fallen to 30. From this time on the improvement, though not uninterrupted, was marked. Before the end of the month he was in the yard daily, and August 6th he was sent to the Convalescent Home, after leaving which, he reported himself once at the hospital. He still had some cardiac symptoms, of course, but was up and about.

The daily amount of urine was, July 2d, 17 oz.; 3d, 19 oz.; 4th, 28 oz.; 5th, 112 oz.; 6th, 53 oz.

CASE II. M., eleven years of age, entered the House of the Good Samaritan, May 17, 1886, for mitral disease, the result of rheumatic endocarditis the previous winter. September 10th, she was sent to the Convalescent Home connected with the institution and stayed till November 20th, when she came back. Under absolute rest, careful feeding and digitalis, she improved for a time, but grew worse again.

January 31, 1887. She was vomiting everything she took; there was marked cyanosis and some ascites, anasarca, and hydrothorax; the jugulars and the liver were pulsating distinctly; the pulse was 120-130; the daily amount of urine had fallen to  $\frac{1}{2}$ -3. Six leeches were ordered over the liver, and, with the subsequent bleeding, the amount of blood lost was estimated at  $\frac{1}{2}$  viii. Immediate relief followed; the vomiting ceased, she had a good night, the next day the venous pulsation was scarcely to be seen, and she eat a good breakfast with relish. The amount of urine rose to 10 oz. on February 1st, to 9 oz. February 2d, 10½ oz. February 3d, 123 oz. February 4th, 60 oz. February 5th.

The pulse fell on the 3d to 90. It is only fair to state that on the 2d, she was ordered tincture of *strophanthus* m.v. t.i.d. I do not doubt that this drug contributed to the diuresis and continued improvement, but from my experience with other cases I am per-

suaed that without the previous leeching it would have been useless. Since then I have pushed the strophanthus up to mvi, t.i.d., the pulse remaining at 108 all the time. There was an interval of a fortnight between the time the strophanthus was omitted and resumed.

The child is now up and dressed all day, and is steadily improving in weight and strength. I believe that her life was saved by the leeches.

CASE III. September 23, 1886, I had the pleasure of accompanying Dr. C. F. Folsom in his visit at the City Hospital, and there saw the following case, the records of which have been most kindly placed at my disposal by him. A woman, past middle age, had been for a fortnight in the hospital with mitral and aortic disease and a failing heart. She had orthopnea, great cyanosis, oedema, jugular and hepatic pulsation. I suggested leeches as a palliative, and twelve were ordered. Their application, the record states, was followed by much relief to the patient, who said she could breathe deeper. The next day she was "very comfortable." The relief was, naturally speaking, in the light of the revelations of the autopsy, only temporary. It was, however, so real, that at her request she was again leeches thrice subsequently, October 4th, 22d, and December 8th. The animals themselves were very repugnant to her, as I am informed by the house-officer, but she craved the relief which they afforded her. Early in January, 1887, she died.

The pathological diagnosis was in part as follows: Aortic insufficiency, mitral insufficiency and stenosis, relative tricuspid insufficiency; hypertrophy and dilatation of the right ventricle and both auricles; chronic adhesive pericarditis with obliteration of the sac; double hydrothorax; embolic infarction of the lungs; venous engorgement of the lungs and abdominal organs, etc.

CASE IV. A well-nourished woman of about fifty entered the House of the Good Samaritan, December 23, 1886, with dyspnea, cyanosis and dropsy, the result of mitral disease. There was also bloody expectoration which was attributed to embolic infarction of the lungs. There was great diminution in the quantity of the urine, and a feeble and very irregular pulse.

When I saw her the next day her condition was desperate, and I immediately ordered twelve leeches in the hepatic region with alcoholic stimulants. No noteworthy relief followed the leeching: the patient dying at eleven o'clock that night.

An autopsy was made sixteen hours after death by Dr. Fitz. Both ventricles, especially the right, were filled with soft clots; the right auricular appendage contained old thrombi; the heart was enlarged; the mitral valve admitted only one finger; the aortic orifice was somewhat diseased. The lungs contained several embolic infarctions of moderate size, old and recent, and were oedematous. The liver and kidneys showed chronic passive congestion. As I look back at this case I think I should have bled her from the arm. The symptoms had grown rapidly worse, and she could have well afforded twenty ounces or more of blood. The result might not have been different. The pulmonary infarction, though not very extensive, was an unfavorable factor in the case, and the auricular thrombosis was a potential source of fresh infarction. When I next meet with a case in which the symptoms are so urgent and have developed with comparative rapidity, the general nutrition of the patient

being good, I propose to bleed from the arm, on the spot, if allowed to do so.

CASE V. A gentleman, forty-five years of age, seen November 27, 1886, in consultation with Dr. A. H. Hodgdon, of Dedham, under whose care he had come that day. He had been in his room, mostly in bed, for weeks, with great dyspnea and other symptoms dependent on cardiac failure. He had taken digitalis, but in what doses was not known, as he had been under homoeopathic treatment. There was oedema of the lungs and right hydrothorax; the liver was distinctly felt two inches below the margin of the ribs; there was no anasarca or ascites. The amount and character of the urine had not yet been determined.

It was agreed that leeches should be applied, and that then elaterium and digitalis should be given.

I have not seen the patient since, but Dr. Hodgdon writes that the relief immediately following the leeches was slight, though the quantity of water increased. The day after the leeching, elaterium was given, acted well, and afforded marked relief. The patient has gained slowly but steadily ever since, but is still compelled to lead a very restricted life.

CASE VI. K., forty-seven years of age, entered the House of the Good Samaritan, November 7, 1885, with cardiac failure, dependent, apparently, on parietal, rather than valvular disease, and a urine indicating more than passive congestion. She was cyanotic and oedematous; there was some oedema of the lungs, and bloody expectoration, with pain in the chest, pointed to embolic infarction. From time to time she grew better, and then worse again.

February 6, 1886. The jugulars were pulsating; the dyspnea and cyanosis were so great, and the pulse so feeble, that twelve leeches were applied, with great temporary relief. A hydropne cathartic and digitalis were then given with success, and the patient expressed much gratitude. Before long, however, the symptoms became grave, and March 16th she died.

The autopsy was made by Dr. Fitz, whose pathological diagnosis was as follows: Chronic interstitial myocarditis; dilatation and thrombosis of the heart; thrombosis of the pulmonary artery; chronic obliterating pleurisy; chronic passive congestion of the lungs, liver, spleen, kidneys, and uterus; chronic interstitial nephritis; chronic gastro-intestinal catarrh.

This is a complete list of the cases in which I have, as yet, used leeches as a means of rapidly diminishing the blood-mass, and thus acting directly on the right ventricle. Case IV received no benefit, but my only misgiving is that enough blood was not drawn. Cases III and VI were greatly relieved for a time, but succumbed to disease, which, post-mortem examination showed, admitted of nothing more than temporary palliation. Of the other three cases, two are known to be alive; the third (I) has been lost sight of. Of these three, two (I and II) would, in my opinion, not have lived more than a few days if I had not drawn blood. Some of the impressions which one receives at the bedside are difficult to convey to others in words. The change which I saw in some of these cases from one day to the next is deeply fixed in my mind, and, I think, also in the minds of the other gentlemen, and of the nurses who were watching the cases.

In short, when the right ventricle is gorged with blood, the leading indication is often to withdraw blood from behind, alcoholic stimulants being given simultaneously by the mouth, or under the skin, as

the features of each case demand. The way is thus prepared for purging and cardiac tonics, which, without the previous relief to the circulation, are quite ineffectual in many cases. In conclusion, I wish to express my obligation to Dr. Broadbent, of London, whose article on "Mitral Stenosis," in the *American Journal of the Medical Sciences* for January, 1886, led me to give more serious thought to the procedure which I have had the honor to lay before you.

## REPORT OF PROGRESS IN ORTHOPEDIC SURGERY.

BY E. H. BRADFORD, M.D., AND R. W. LOVETT, M.D.

### LATERAL CURVATURE.

SIGFRED LEVY<sup>1</sup> holds that there are two distinct etiological factors in the production of habitual scoliosis: one, "an anomaly of nutrition," a purely organic matter; secondly, certain mechanical causes—faulty positions of standing and sitting. Neither one of the factors can cause it alone; both must be present at the same time. In support of this view, he speaks of a case which he saw, where a girl of three years had a resection of the knee, and grew up with one leg nine centimeters shorter than the other. The pelvis was always tilted, but there was no suspicion of scoliosis until she was twelve years old, when she began to have headache, pain in the side, malaise, etc., and in spite of all precautions, a typical lateral curvature rapidly developed. He has seen three other such cases; and in over a hundred cases of habitual scoliosis which he has observed, in every case symptoms of general disturbance (as in the case related above) accompanied the development of the deformity.

### CONGENITAL DISLOCATION OF THE HIP.

Motta<sup>2</sup> advocates a simple method of treatment, which, he says, gives "an immediate correction, or, at least, a decided lessening of the limp." The patient is suspended, as if a plaster-jacket were to be applied. If it is a unilateral dislocation, the shortened leg is drawn forcibly downward, and a plaster-mould of the whole side is taken, reaching from the axilla to the knee. From that a poro-plastic felt splint is made, which laces up, and is worn during the day. At night, extension is continued by a gaiter and attached weight, and the felt splint is applied in the morning, before the weight is removed. The treatment for double dislocation is simply a repetition of the same process on the other side.

### COLD ABSCESSSES.

Garré<sup>3</sup> searched very carefully for tubercle bacilli in the pus from thirty cold abscesses, from different patients, but he only found them in a very small proportion of these cases. From attempts at cultivation from the pus in the class of cases where bacilli were not present, he got negative results; but inoculations of this pus in animals gave a typical tuberculosis, with many bacilli, and led to the inference that tubercle spores must have been present in the original abscesses. From this, Garré concludes that the conditions necessary for the development of tubercle bacilli from their spores exist only in the living organism.

### DEFORMITIES AND ARRESTED GROWTH.

Nicoladoni<sup>4</sup> describes a case of manus vara and a case of manus valga, where the deformity was due to an injury of the epiphysis of the radius in one case, and of the ulna in the other, and a consequent arrest of growth. He then relates the case of a young man who received an injury of his knee-joint, and where, for nine years, the knee had been flexing more and more, by degrees. This thigh was ten centimeters shorter than the other, and his leg nine centimeters shorter. Two similar cases of Billroth's are related, and all are considered due to premature synostosis of the lower epiphysis of the femur, consequent upon injury. The reviewer of Nicoladoni's article, Roser, says that in all three cases there was a latent tuberculosis, and a consequent fixation in slight flexion, which was increased by walking about on the leg. Nicoladoni next considers the asymmetry of the head in torticollis. It affects only the upper jaw and base of the skull, while the lower jaw and vault of the skull are alike on the two sides, and he shows that it is a deformity due to the unequally disposed weight of the head. The scoliosis accompanying torticollis is purely the result of holding the head sidewise, a compensation entirely mechanical. He closes by giving an account of the examination of the vertebral column from a case of rachitic lateral curvature, where ossification had gone much further in the parts of the vertebrae on the convex side of the curve.

### TRACTION IN CLUB-FOOT.

The most important article for some time on the subject is furnished by Shaffer,<sup>5</sup> who writes of the use of traction, and describes the two shoes which he uses for this treatment. The two shoes are the outgrowth of the antero-posterior traction-shoe, and the simple, lateral pushing-shoe already described by him. The principle involved is as follows: The centre of motion in flexion and extension of the foot is not at the ankle-joint, but just below it. Therefore, in passing from extension to flexion of the foot, the heel rotates downward and forward, the toe upward and forward, and the astragalus upward. In short, the heel rotates downward, and the neck of the astragalus upward, around the transverse centre of antero-posterior motion at the ankle-joint. In criticism of the conventional forms of apparatus, he says: "The point at which the retaining force or counter-pressure is made (the neck of the astragalus) must also rotate around the pivotal point." When, therefore, motion is attempted with this apparatus under these conditions, the foot cannot follow the mechanical law of antero-posterior motion, and the heel cannot be carried downward and forward. The antero-posterior traction-shoe (for talipes equinus) consists of a calf band and two uprights, with a heel-cup and sole-plate. Antero-posterior motion of the shoe can be obtained at the ankle by an endless worm and screw moving the whole foot-piece, and controlled by a key. At a place corresponding to the medio-tarsal joint, the sole-plate is divided transversely, and the two parts, anterior and posterior, are connected by a traction-rod, with ratchets, worked by a key under the heel-cup. Two webbing straps are applied to the foot: one over the astragalus, and one around the heel. They cross each other, and the ends of the former are fastened to the

<sup>4</sup> Centralblatt für Klin. Chir., No. 10, 1887, p. 181.

<sup>5</sup> N. M. Shaffer. *New York Medical Journal*, March 5 and 12, 1887.

heel-cup, and the heel traction-straps are carried forward to the anterior end of the shoe, and buckled. The ankle-joint of the shoe is set to fit the deformity, and, by tightening the straps, the foot is pulled down on to the shoe. Then loosen the strap over the head of the astragalus, to allow it to rotate. By the key, the foot is brought to a right angle. Then the forward part of the sole-plate is separated from the other; it pulls on the heel traction-strap, and the heel is pulled irresistibly downward and forward. Shaffer states that a temporary gain of one-eighth to one-fourth of an inch in the length of the foot is not unusual after a single treatment of fifteen minutes.

The lateral traction-shoe is to be used for talipes varus and varo-equinus. The motion in the antero-posterior direction at the ankle is the same as in the other shoe, and there are two other entirely distinct motions: one an eversion of the whole foot-piece by a hinged lever and screw, just below the ankle; and the other a revolution outward of the anterior part of the sole-plate, with a point of motion for this revolution at the junction of the os calcis and cuboid. The foot is held by a raised inner border to the sole-plate. Any detailed description of the apparatus would be unintelligible without figures. The shoe is set to fit the deformity, and applied; and then, by the keys, the foot is brought into a more correct position. This shoe is worn, most of the time, with very gentle traction applied; and exaggerated traction is applied (as much as can be borne), at intervals of an hour. Shaffer states that certain cases do not yield readily, but, even after tenotomy, the shoes are very useful.

#### RESECTION OF THE TARSUS IN CLUB-FOOT.

Krauss<sup>6</sup> formulates the objections against tarsal resection as a means of treatment for inveterate club-foot as follows: (1) The different methods of resection of the tarsus impair the form of the foot and the stability of its osseous arch, with a consequent impairment of mobility and usefulness. (2) Resection, as an operation, is not free from risk. (3) The extirpation of the astragalus is a more suitable operation for restoring the form of the foot than the removal of a wedge in the direction of the medio-tarsal joint; but it leaves an immovable ankle, or one partly so, a weak union between the os calcis and the second row of tarsal bones, and serious shortening of the foot. (4) Resection removes all chance of future restoration by orthopedic treatment. (5) "There is no conceivable form of club-foot in which tarsal resection is justifiable, except it be in the case of one that is persistently painful in an old subject, and in which there is no prospect of a good result from orthopedic treatment. In such a case resection may be fairly tried, instead of amputation."

#### CLUB-FOOT.

Churchill<sup>7</sup> speaks of the necessity of early treatment, and describes a new form of retentive apparatus, which differs but little from the ordinary plaster-bandage, except in being somewhat more complicated. He manipulates the foot, and renders it as flexible as possible. Then a flannel bandage is wound on quite firmly, and carried up the leg. Some strips of broad webbing are then put around the forward part of the foot, to protect it, and a strip of perforated tin, bent at a right angle, is used on the outside of the leg as a

stirrup, to hold the foot in its corrected position. Plaster-of-Paris is then put on outside. It is difficult to see what advantage the method has over the ordinary plaster roller applied to the foot held in an approximately correct position. Mr. Churchill advocates the view that intra-uterine pressure is, in some way or other, the cause of the deformity. Of the bones, tendons, ligaments, and fasciæ, he says: "Each become subject to the contractile force of the involved muscles in their relative proportions"; and it is this that he means when he speaks of the "multiple causation of club-foot."

#### FLAT-FOOT.

Mr. Collier<sup>8</sup> takes issue with the views expressed by Humphreys<sup>9</sup> as to the causation of flat-foot. He says that the astragalus is not the keystone of the arch of the foot, for it does not transmit equally to both extremities of the arch the weight of the body in standing. Only a small part of the body-weight is transmitted through it, comparatively speaking, and most of the weight goes to the os calcis, and through it to the ground. The plantar fascia and ligaments, with tendons assisting, maintain the normal position of the os calcis. Ligaments will atrophy and stretch when they are overstrained; but they do not grow weak and then stretch, so that the cause cannot be want of tone in the ligaments. The flattening is due to an antecedent alteration in the position of the os calcis, which comes about in this way: As long as the foot rests on a horizontal surface, the os calcis is capable of supporting the astragalus and any reasonable weight without the intervention of any ligaments (as shown by some experiments mentioned). But if the heel is raised, the body-weight is not transmitted so directly through the os calcis, but the astragalus slides forward on the os calcis, and throws the weight of the body on to the calcaneo scaphoid, interosseous, and plantar ligaments. Atrophy and stretching of these ligaments follow. That the affection is more common in girls than in boys, and in the upper classes more than the lower, is due to the wearing of heels. The treatment is the removal of the heel of the shoe. As to a pad along the inside border of the foot, it is comfortable, because it helps support the anterior extremity of the os calcis; but it compresses the internal plantar nerve, and should never be used. As much rest as possible should be taken, and the front part of the sole should be raised. In fact, the heel should be worn in front, instead of behind.

To this Ellis<sup>10</sup> replies in a short letter, objecting to the following points: That the astragalus does not move forward, when the heel is raised, so much as downward and inward. That the deformity is not diminished in the bare-footed patient by raising the toes, but that when the heels are raised, and the patient stands on tip-toe, that the deformity disappears. He therefore recommends that the patient be directed to perform this exercise of rising on the toes daily; that the feet be inverted during sleep by some simple appliance; and that a springy walk be cultivated, the patient keeping the heels off of the ground as much as possible.

#### A PAINFUL AFFECTION OF THE FOOT.

Morton<sup>11</sup> describes an affection characterized by in-

<sup>8</sup> Lancet, 1886, II, 441.

<sup>9</sup> Lancet, 1886, I, 329.

<sup>10</sup> Lancet, 1886, II, 604.

<sup>11</sup> Philadelphia Medical Times, October 2, 1886.

<sup>6</sup> Krauss. Fifteenth Congress of the German Surgical Society.

<sup>7</sup> Brit. Med. Journal, November 27, 1886, p. 1025.

tense pain, referable to the head of one of the metatarsals, usually the fourth, consequent on a strain or twist of the foot. It seems to be a neuralgia of one of the internal plantar nerves, which are liable to be compressed, and even pinched, by a sudden twist of the anterior part of the foot, by virtue of their position. The treatment should be local depletion, anodynes, rest, and a broad-soled shoe. A flannel bandage, tightly compressing and holding firm the anterior part of the foot, generally gives perfect relief, but sometimes the affection is so severe that excision is necessary.

#### CLUB-FOOT.

German surgeons do not look with very much favor upon Phelps's method of treating club-foot by a transverse incision to the bone across the sole. Philippson<sup>12</sup> discusses it at length; after speaking of the methods of Wolff, Lorenzo, and others in the treatment of inveterate talipes barus, he quotes Wolff as saying that the operation of Phelps is a rough and unjustifiable cutting through the moderately thick soft parts with all the contained muscles, nerves and vessels. Philippson, himself, regards it in the same light. In the first place, purely orthopaedic treatment will often suffice to effect a cure in such cases. Then the operation needs many assistants and cannot therefore become very popular. Moreover, it is not complete treatment, it is only preliminary and is succeeded by a most painful convalescence. Cutting the soft parts and roughly wrenching the foot into place also tends to dislocate the deformed bones, to destroy the existing tarsal joints. On these grounds he opposes the operation very strongly.

#### RESECTION OF THE ANKLE.<sup>13</sup>

The methods of Kocher, in use by him since 1883, is as follows: The foot is held at a right angle and a superficial incision is made along the outer border just below the external malleolus reaching from the tendo achillis to the extensor tendons. The peroneal tendons are dissected out, secured by sutures, and then cut by a second and deeper incision. The ankle-joint is opened very easily and the capsule along the anterior and posterior surfaces of the tibia is cut. The foot is then dislocated inward as far as is desired, and the joint can be inspected to any extent. After the diseased parts have been removed, the foot is reduced to its proper position, the peroneal tendons united and the wound closed. The operation differs from that of Reverdin in not cutting the tendo Achillis and in preserving the peroneal tendons. Five cases with very good results are related.

#### RESECTION OF THE KNEE.

Lucas Champouñère<sup>14</sup> speaks of the resection of the knee and advances rather radical views in certain points. Suppuration after operation, he considers an evidence of failure, and unless it is extremely limited, as an imperative indication for amputation. He reports a series of eleven cases, in adults, all of which recovered. All, except one, were for tubercular arthritis; nine got well without any suppuration; one had very slight pus formation, and the other had so much suppuration as to necessitate amputation. The patients walked one to two months after opera-

tion. He does not recommend the operation for children, as it interferes so much with the growth of the limb, nor does he consider tuberculosis of the lungs in a reasonably early stage as a necessary bar to operation.

#### PARALYTIC CLUB-FOOT.

Lesser<sup>15</sup> reports the examination of a paralytic club-foot, operated on by him seven years before. The object aimed at was to secure after correction an ankylo-sis of the ankle joint (by operative means) with the foot in a corrected position, enabling the patient to walk without the use of appliances and without danger of relapse. This method was described<sup>16</sup> and has been repeated by Rydygier, with satisfactory results in two cases.

Lesser's patient was able to walk about freely without apparatus or cane, and could stand, with slight help, some little time on the left foot alone. The ankle was ankylosed, but there was an increased amount of motion at the Chopart articulation. The patient walked well on the flat of the foot.

#### RESECTION OF THE KNEE IN CHILDREN.

Peterson<sup>17</sup> reports the case of a young man who died five years after an excision of the knee, and whose skeleton was very carefully measured to ascertain the growth of the affected leg subsequent to operation. He was operated on by Esmarch in 1880, when he was eleven years old, and he had at that time three cm. shortening of the leg; an ordinary intra-epiphyseal operation was done. The wound healed, and in five weeks he was about again. Five years later his leg was still useless although the knee was ankylosed in good position. He had sixteen cm. shortening, and desired amputation, which was done, and he died of fatty degeneration of the liver. The bone shortening proved to be thirteen and one-half cm. The left femur was eight and one-half shorter than the right and the left tibia five cm. shorter. It was found that if the upper and lower halves of each tibia were measured separately that the difference in the length of the upper halves was two cm., while that of the lower was three cm. The nutritive foramen was taken as the dividing line. That is, the shortening was not due so much to destruction of the epiphysis as to an arrest of growth of the whole leg. The femur showed the same point.

He concludes that resection is far from preventing atrophy and very serious shortening; and in children he considers the advisability of the operation to be still an open question.

#### JOINT RESECTION AND GENERAL TUBERCULOSIS.

Wartmann<sup>18</sup> has investigated the results in seventy-four cases of excision for tubercular arthritis in the Hospital at St. Gallen; eleven died, and of these, two died of "operative tubercular infection," as Wartmann calls it. In further statistics he found that of 837 resections (and secondary amputations) 225 died, of whom twenty-six had acute general military tuberculosis, whose outbreak came so soon after operation as to suggest very strongly a causal relation.

Pilcher,<sup>19</sup> on the other hand, discussing more especially the effects of such resections on patients with

<sup>12</sup> Centralblatt f. Chirurgie, No. 46, 1887, p. 797.

<sup>19</sup> Revue de Chirurgie, January, 1887.

lung tuberculosis, concludes: that when a lung tuberculosis is present, and an operation for the relief of a coexistent bone or joint affection is indicated, as the result of such an operation, the lung affection, while in some cases uninfluenced, is more frequently checked in its progress, and sometimes is apparently entirely recovered from." That local relapse is conditional on incomplete operation; and that where doubt exists as to the possibility of the removal of all the diseased tissue by the more conservative methods of arthrectomy or excision, the coexistence of lung tuberculosis would add weight in favor of doing amputation.

#### POTT'S DISEASE.

Neidert<sup>20</sup> has investigated the cause of death in patients with angular deformities of the spine, the result of Pott's disease which has been cured. Patients with severe deformities die of heart fatigue ordinarily, patients with medium-sized curvatures die oftenest of phthisis, and die young, while those with small deformities have nearly as good a prospect of long life as men with normal spines. These results were obtained from the investigation of thirty-one specimens in the Munich Pathological Institute. The average age of the patients at the time of death was forty-nine and one-half years. Twenty-four had hypertrophy, with or without dilatation, of the right side of the heart, four had muscular degeneration of the heart walls, and two had stenosis of the mitral valve, one showed acute miliary tuberculosis, eight died of phthisis, four of pneumonia, and one of carbuncle.

Lannelongue,<sup>21</sup> speaking of narrowing of the aorta in Pott's disease, says that in his autopsies he has noted that a very marked narrowing of the calibre of the aorta was not uncommon. In one specimen the aorta only measured sixteen mm. before the origin of the brachiocephalic trunk; twelve mm. after the carotids had been given off, and only eight mm. in the region of the second lumbar vertebra. In another specimen the lumen of the aorta was reduced to a mere slit. These changes are consequent upon the abnormal curves given to the vessels, and their existence explains the production of certain rapid and peculiar paralyses which come on in spinal caries and which are not due to compression of the cord.

H. L. Taylor<sup>22</sup> gives nine cases where recession of the deformity has taken place under treatment by the Taylor back-brace. He states, first, that "the average ultimate result in Dr. C. Fayette Taylor's private practice, using his antero-posterior leverage supporting and protective apparatus, thoroughly and for a sufficient length of time, has been, under favoring conditions of attendance and home attention, the definite arrest of the deformity at, or near the point it had reached before such protection was furnished." In certain cases, however, he notes that the deformity will increase in spite of all care.

The straightening of the curved back to which he refers, is not merely the obliteration of the compensatory curves, but a real diminution or disappearance of the angular projection. The cuts that accompany his article show that plainly enough.

Of the nine cases, one was dorsal disease, three were dorso-lumbar, five were lumbar entirely. In five, the knuckle completely disappeared, while in the others the improvement was very marked. The

time for disappearance ranged from three to ten years after the beginning of treatment. The case of dorsal disease recovered wholly. The cases are given in full in the article.

Noble Smith<sup>23</sup> calls attention to the frequency with which Pott's disease is overlooked by the medical man, and tells of some remarkable specimens to be found in the London Hospitals, where extensive destruction of the vertebrae had taken place, and yet when the symptoms during life had been most insignificant. Notably, that of Dean Buckland, whose symptoms were those of "melancholia" where after death there was found extensive caries of the first three cervical vertebrae. Mr. Smith mentions the affections for which spinal caries is commonly mistaken and gives the differential diagnosis.

#### OSTEOCLASIS.

Pousson<sup>24</sup> has written a very complete treatise on osteoclasia. After giving a history of the development of the operation he classifies present methods as follows:

By vertical pressure, manual or instrumental; by flexion, manual or instrumental; by traction in the axis of the limb, manual or instrumental; by torsion, manual.

Under these headings he classifies all osteoclasts and all methods, and describes especially the apparatus of Robin and the old and new osteoclasts of Collin. Aysaguer's experiments in manual osteoclasia are summarized. In children two years old the fracture is generally incomplete, above four or five years there is ordinarily true fracture, always simple, and rupture of the periosteum. Di Santi experimented on subjects from eighteen to twenty-two years old; in twelve there was no epiphyseal separation, but nine times there was found rupture or detachment of the lateral ligaments, and twice a bit of condyle torn away with them, while once the whole condyle was torn away, making a fracture into the joint.

Pousson discusses osteotomy, which he treats most unfairly, and advocates osteoclasia very strongly for the correction of rachitic curves. So good is the apparatus of Collin that Delens and Demons, formerly advocates of osteotomy, have abandoned it for osteoclasia. He reports thirty-six osteoclasts for ankylosis of which eighteen were of the hip and fourteen of the knee. The results were classed as perfect in twenty-four, satisfactory in three, tolerably satisfactory in one, and bad in two; four were unclassified. In no case was there a relapse to the former condition.

#### BONE GRAFTING.

Poncet<sup>25</sup> has had a notably successful case of bone restoration in a child eleven years old, whose entire tibia for thirty cm. was lost by necrosis. Small pieces of bone were taken from the tibial epiphysis of a new-born child, and of eight grafts, five remained and grew. Nine other grafts were then taken from a young goat and of these, three remained. In six months after the operation of sequestrotomy the child had a tibia only three cm. shorter than the one on the other side, composed of hard, firm, healthy bone. Poncet lays down the following rules: the fragments to be used should not be larger than ten mm. long,

and four mm. thick. They should be taken from places where ossification is most active, and the best time for grafting is immediately after the removal of the sequestrum. Perfect rest and asepsis are of the greatest importance in the after-treatment.

#### RACHITIS.

Kassowitz<sup>26</sup> publishes very extended studies upon 5000 cases of rachitis observed by him. Genu valgum and flat-foot from standing, are so essentially rachitic that he would treat the latter at least by phosphorus from the start. As to the muscular weakness of rachitic children, he says that on account of having pain in the joints on movement such children learn to sit up and to walk very late, and that the muscular atrophy found is that of inactivity. He holds it very probable that most of the crooked thighs and tibiae are due to the tonic action of the muscles primarily, and that the body-weight only serves to increase the bend when the child begins to stand and walk. As to fractures in rachitic bones: when found they lie on the convex side of the bend almost always, and are deep, often involving half the circumference of the bone and showing a sharp angular nicking of the bone. If the bone is broken wholly across, the periosteum is apt to remain intact. Callus formation is slow, but pseudarthroses are rare. In these 5000 cases there were noted ninety-nine fractures, and in the long bones the crack seemed almost always to be in front or in front and outside. In conclusion, he says: "It appears surely established that the deformities of the joints, even those occasioned by standing, are not brought about by inequalities of growth, but solely and alone by compression and bending of the weakened bone and cartilage layers and by the consequent alterations in the position of the bones at the joints."

Toeplitz<sup>27</sup> does not agree with Kassowitz as to the time of beginning of rachitis. In his cases only about twenty-five per cent. of the cases showed traces of bone rachitis in the first three months. Toeplitz has treated 518 cases with phosphorus in the last two and three-quarters years. His dose is two-thirds of a milligramme to a milligramme morning and night. Treatment lasted from four weeks to ten months, but in very many cases improvement was clearly to be seen in two or three weeks, especially in the general condition of the patient. Craniotabes, laryngeal spasm, delayed dentition, all yielded readily to this treatment in a few weeks, and all the symptoms disappeared more readily than under other treatment. Bad effects from the treatment, such as dyspepsia and diarrhoea, were not seen in any cases.

#### RUPTURE OF THE SYNOVIAL MEMBRANE OF THE KNEE.

After a severe attack of articular rheumatism, of gonorrhoeal origin, the patient, reported by Ponvost,<sup>28</sup> presented a large effusion into the knee-joint, which improved somewhat under treatment, but which increased on the patient's attempt to walk. After a sudden movement in bed, the patient felt a severe pain in the knee and thigh, and on examination the swollen knee was found to be normal in size, and free from pain, but there was an increase in the circumference of the upper part of the thigh. Compression was applied and no return of the swelling took place. The

patient stated that a similar accident happened to the same knee eight years before.

#### RESECTION OF THE JOINTS FOR ANCHYLOSIS IN FAULTY POSITIONS.

Köl liker<sup>29</sup> reports several cases; among them were four operations on the hip and two on the knee. He modifies the typical operations to suit each case. For the common deformity of the hip, adduction and flexion, he uses Langenbeck's posterior incision, while in the knee he prefers the curved transverse incision below the patella. The after-treatment is the same as in typical resections. The results were good in all cases.

## Clinical Memorandum.

### MENTAL DISTURBANCES FOLLOWING THE CESSATION OR DIMINUTION OF EPILEPTIC ATTACKS UNDER TREATMENT.<sup>1</sup>

BY L. W. BAKER, M.D., BALDWINVILLE, MASS.

OCCASIONALLY cases of epilepsy are met with in which the cessation of convulsive attacks is followed by more or less mental disturbance. When this event occurs it is generally regarded as due to the medicine taken, which is consequently discontinued with the result of the continuance of the attacks with their accustomed frequency. In those patients exhibiting this condition which have come under my observation, a different view has been taken, as illustrated by the following cases.

A young gentleman, eighteen years of age, having several severe convulsions daily, was sent to me with the request that I abstain from the use of the bromides in treating him, as previous attempts in the use of these remedies had caused insanity. After watching the case carefully for several days, I decided to resume the bromide in doses of about fifty grains daily, at least temporarily. The convulsions at once ceased and have not since returned for a period of nearly three years. Mental excitement, however, soon appeared, accompanied by sleeplessness, and by the most violent exhibitions of temper, and intolerance of any attempts of control, the slightest cause being sufficient to excite a paroxysm of noisy rage, although no delusions were present. Notwithstanding the mental disturbance the original plan of treatment was steadily followed, combined with treatment intended to allay the mental excitement. A few months' perseverance in this line accomplished the desired result and his mind gradually returned to its normal condition. He always has been and always will be, feeble-minded, but there has since been no tendency to any mental convulsion.

Another case was a young lady who was sent to me from New Jersey. On her arrival she was maniacal, had various delusions and was quite difficult to manage. She was then undoubtedly in a state of bromism, which for a time gradually grew worse. This patient has now been under my care for over a year and during this time the bromide treatment has once or twice been suspended for varying intervals of time with the immediate effect of increasing the frequency of the attacks, while the mental condition materially improved. A return to treatment intended to allay the convulsive tendency was always followed by a return of the mental disturbances, although with lessened severity, still, this latter plan has been patiently followed for several months in connection with nerve tonics, nourishing food, and out-door exercise, with the result of a great improvement in the mental condition and a lessened frequency of the convulsive seizures.

Another patient, a young lady of twenty-five, had for years a weekly convulsion, preceded for hours by an indescribable dreamy feeling. These attacks were at once almost entirely controlled by treatment, but considerable mental confusion soon supervened and she was unable to perform mental acts which had previously given her no trouble; she could not read with

comfort, could not write connectedly, and the peculiar aura instead of being paroxysmal was constantly present.

The anti-convulsive treatment was, however, continued, notwithstanding these symptoms, and she has completely regained her normal mental condition and is now better than she has been for years.

These examples, are, I think, sufficient to illustrate the statement, that anti-convulsive treatment should not be too readily abandoned when mental disturbances follow the cessation of convulsive seizures. In these cases the brain has become accustomed to excessive discharges of nerve force, which occasion muscular convulsions; when this tendency is controlled by treatment the equilibrium of the nervous centers is for a time destroyed, the discharge then becomes mental, rather than motor, and there ensues a convulsion of ideas instead of a convulsion of muscles. If the anti-epileptic treatment is combined with cod-liver oil, phosphorus, and other nerve tonics, the brain will, I think, gradually return to the condition in which it was before the attacks were controlled.

Of course, in these cases it is important to distinguish between this condition and that which is occasionally produced by large doses of bromide of potassium, but in the majority of instances, I think it will be found that the mental disturbance is due to the cessation of convulsive attacks rather than to the effects of the drug. In the cases above quoted only comparatively small doses of bromide were used, the average dose being about forty-five grains daily.

Many of these patients, however, will need to be removed from home and treated apart from other patients. They should not be sent to an insane asylum, if possible to avoid it.

## New Instruments.

### A NEW APPARATUS FOR PREPARING DRY GYPSUM BANDAGES.<sup>1</sup>

BY H. AUGUSTUS WILSON, M.D.

ROLLING the dry plaster-of-Paris bandages by hand, the method usually in use, is unsatisfactory, and under the most favorable circumstances a dirty process. It was to avoid the inconveniences and irregularities of that method that I devised this apparatus, which I have had made by A. G. Gefvert, the orthopedic apparatus manufacturer.

It consists of an ordinary box-bandage roller, with the addition of the following: A movable bottom, A, A, A, held in contact with the outermost layer of the bandage, as it is rolled, by a rubber band, B, and at the other end by a hinge-joint C. Upon this movable bottom, and just in front of the crank, is a flood-gate or distributor, not shown in the illustration, which equalizes the distribution of the plaster and presses it into the bandage from above, while the movable bottom prevents the gypsum from passing through the meshes. The proper tension is applied by two rubber bands.

A hopper, E, is provided with an arm, F, bent in such a manner as to be raised by the crank at each half turn, and upon being released, it falls, throwing

<sup>1</sup> Extract from a paper on "Mental Epilepsy," read before the New York Medico-Legal Society, December 8, 1887.

<sup>1</sup> Read before the Philadelphia County Medical Society, State Medical Meeting, February 9, 1887.

down a quantity of the powder upon the bandage in front of the distributor. A compartment, H, H, H, occupying the otherwise waste space under the movable bottom, is utilized as a receptacle in which may be kept the gypsum when the apparatus is not in use.

A scoop accompanies the apparatus with which to take gypsum from the compartment and fill the hopper. The entire affair can be securely held to a table by a clamp, K. Elastic bands are used for springs, because they are inexpensive and can be very readily replaced when worn out.

The method of using is, first to pass the end of the bandage to be rolled over the movable bottom, under the distributor, and attach to the crank. The hopper is now to be placed in position and, by means of the scoop, filled with a sufficient quantity of gypsum. While the crank is turned with the right hand the left guides the bandage, which may be watched, over the hopper, as it is being rolled.

The bent arm of the hopper is so arranged that the fall of the hopper may be sudden or gradual, and upon this depends the quantity of powder discharged. When the crank is turned very slowly the hopper is raised slowly and descends with the motion of the crank, and scarcely any gypsum is precipitated, and, of course, the converse follows. This being clearly understood, a very slight experience will enable any one to control the action of the hopper with the crank.

When a bandage is finished, the crank is withdrawn sufficiently to disengage it from the bent arm of the hopper, and while the left hand holds the bandage, a quick reverse turn of the crank enables it to be easily withdrawn. The gypsum remaining on the movable bottom is now discharged into the compartment by placing the hopper to one side, detaching the spring, B, and raising that end.

The apparatus is applicable to the rolling of the ordinary surgical bandage by detaching the rubber spring, B, thus allowing the movable bottom to drop out of the way. It prepares the dry gypsum bandages evenly and quickly. It is very simple in its construction and action. It cannot get out of order, except by the breaking of the rubber bands. It is inexpensive.

Possessing these advantages, I hope it will be of service and facilitate the preparation of the dry gypsum bandages in the hands of other physicians as it undoubtedly has in mine.

—The Medical Society of Athens celebrated its semi-centennial anniversary April 3d and 4th, by a congress of Greek physicians.

## Reports of Societies.

### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. DUCKINGHAM, M.D., SECRETARY.

MARCH 28, 1887, the President, DR. O. F. WADSWORTH in the chair.

DR. G. H. LYMAN reported a case of

#### ANEURISM OF THE INNOMINATE ARTERY.<sup>1</sup>

DR. G. W. GAY, who was unable to be present, sent the following, which was read by Dr. Lyman.

Dr. Gay wished to call particular attention to the method of tying the arteries in this case. It was suggested to him three or four years ago by the failure of a case of a single ligature applied to the femoral artery. By applying two ligatures to the vessel, and thus cutting it completely across, we follow one of Nature's most important laws; we thereby allow the divided ends of the artery to retract within the sheath, and thus remove all tension upon the vessel. This process is one of Nature's hamastatics, and a very important one. Unless the vessel is divided in this way every motion of the part during convalescence is liable to destroy the adhesions, and give rise to secondary hemorrhage.

While this method of tying arteries is an old one, yet it has received little attention in the text-books. When a large artery is wounded we are very properly told to apply a ligature above and below the wound. Having done that, why not divide the artery completely? It would seem to be the only sensible thing to do, and I would strongly urge this method of tying arteries in their continuity, upon the profession.

DR. G. B. SHATTUCK, who had succeeded to the charge of the patient at the close of Dr. Lyman's term of service, said the case illustrates the great difference in patients. With many it would have been simply impossible to carry out the treatment as detailed. This must be irksome enough, even where the patient has the advantage of a window with a good outlook and with friends to amuse him with reading and conversation. In a hospital ward the tediousness must be increased. This was a man of intelligence and with self-control unusual in any walk of life. It was possible to keep him in absolute rest and on limited diet for a long period. Some patients are not susceptible of benefit from the treatment, but whether susceptible or not, it is simply impossible with many people.

The speaker did not know whether Dr. Lyman thought that the attack of eighteen months before was indicative of aneurism or not, probably it was, and it seems fair to assume that the lesion existed at least that long before entering the hospital. Adding to this, the part of his life subsequent to admission, gives a total duration of disease of nearly three years. Inasmuch as fifty per cent. of these cases die within a year and seventy-five per cent. within two years, it must therefore be assumed that his life was prolonged by treatment. Diet was not restricted entirely to the limits recommended by Tuffnell, of ten ounces of solids and eight ounces of liquid in the twenty four hours.

DR. LYMAN said that the use of iodide of potassium

<sup>1</sup> See page 303 of the Journal.

is supposed to further the deposit of fibrinous layers. It has been used in aneurism and offers some hope of success. Pressure offers a hope of relief, at least, if of not even better results. In this case no effects were seen of pressure upon the recurrent laryngeal until within the last forty-eight hours. Dr. Lyman further said that when Dr. Gay cut through the artery as described in his note, that it was very noticeable to what extent retraction took place.

DR. E. H. BRADFORD said that he remembered seeing the patient in the hospital, although not in his service. He knew that the question of tying the carotid and the subclavian at one operation had been considered at the time.

DR. C. B. PORTER said that not having heard the whole discussion, he should not wish to be considered as reflecting at all upon the treatment of this case, for which undoubtedly there was a good reason. Upon general surgical principles it would seem better to tie both the carotid and the subclavian at one operation, inasmuch as the aneurism included both, remembering also that collateral circulation may be established in a very short time.

[The reason for not tying both vessels at the first operation was that the shock would be very great; and that the operation of tying the subclavian would be prolonged from the fact that it could not be felt, and that the pulse was very much weaker than upon the opposite side, showing marked diminution in the calibre of the vessel. The slight amount of disturbance that followed the application of ligatures in the above method would lead me to tie both vessels at one time under similar circumstances in the future. G. W. G.]

DR. F. C. SHATTUCK read a paper entitled,

SIX CASES OF OVER-DISTENSION OF THE RIGHT VENTRICLE TREATED WITH LEECHES.<sup>2</sup>

DR. C. E. STEDMAN inquired if leeches were applied over the liver rather than over the heart for any reason other than convenience.

DR. SHATTUCK replied that it was only for convenience.

DR. STEDMAN asked if in case leeches did not bite well, would the reader bleed from the arm, rather than wait.

DR. SHATTUCK said that he would.

DR. STEDMAN said that that was his idea also.

DR. F. C. SHATTUCK reminded the Society that Dr. Westbrook, of New York, had under similar circumstances aspirated the right auricle with very speedy relief in two cases which had been published and in which resulted from the operation no bad symptoms. The same gentleman had, however, recently had a death from leakage at the point of puncture, so that he will probably not repeat the operation.

NECROSIS OF THE PETROUS BONE. REMOVAL OF A SEQUESTERUM CONTAINING THE VESTIBULE AND SEMI-CIRCULAR CANALS.

DR. J. ORNE GREEN showed the specimen, which consisted of a sequesterum five-eighths of an inch long and three-eighths of an inch wide, and which showed distinctly the osseous vestibule and remnants of the three semi-circular canals. The patient, a child aged two and a half years, ill-nourished and with caries of the dorsal vertebrae, had shown an otorrhea on the

left side for some two years, to which no attention had been paid, and within a few months paralysis of the left facial had developed. The meatus was filled with a large polypoid growth, behind which bare bone could be felt over a surface at least half an inch long and a quarter of an inch wide, and palpation with a probe showed a sequesterum slightly moveable, but too large to be removed through the meatus, and too deep to be broken up.

Under ether the auricle and cartilaginous meatus were displaced forwards but the sequesterum was too firmly imbedded in the surrounding bone to be withdrawn. The mastoid tubercle was then exposed and almost the whole of this, together with whatever had formed of the osseous meatus, was removed with a chisel, and the sequesterum finally withdrawn in the condition shown: a few small fragments came away separately on syringing the cavity. The bleeding from the granulations surrounding the necrosis, was quite free but not alarming. For a few days the wound and cavity were dressed twice a day, by douching with carbolic solution 1-60, and then sprinkled thoroughly with powdered iodoform; after this the dressings were continued once a day, and now, about three weeks after the operation, the wound is healed and all discharge from the meatus has ceased. The facial paralysis still remains.

NEW YORK COUNTY MEDICAL ASSOCIATION.

STATED meeting, March 21, 1887.

The President, DR. JOHN SHRADY, read a paper on

THE ANEURISMAL DIATHESIS,

in which he arrived at the following conclusions: The subject of aneurism, presenting, as it did in its various relations to mechanics, etiology and pathology, many points of interest, it was within the scope of the paper to discuss. It was sufficient to call attention to various forms of the human physique which were likely to indicate tendencies in this direction and which might, perhaps, start an impetus to further investigations. He was, indeed, not yet sufficiently settled in his own convictions to propose any law comprehensive enough to embrace all the cases observed or reported; but he thought he was warranted in the statement that a tendency to aneurism might be recognized to exist in the following instances:

(1) In individuals possessing a large, not necessarily hypertrophied, heart, the pulsations of which are quick — say over eighty-five to the minute — and forcible; this condition generally being present in the long-bodied and short-limbed. These individuals are necessarily muscular, to compensate for a relatively poorly developed osseous system.

(2) There are certain racial configurations in which fatty degenerations are prominent, as, for example, among the Teutons, and exceptionally among the Celts, in which the aneurismal tendency is a marked feature.

(3) There may be an induced or cultivated diathesis, as among those addicted to athletic sports who primarily overtax the heart, and secondarily the circulation.

(4) Obesity, as presenting an enfeebled resistance to forces which have been adjusted to a different condition of things.

<sup>2</sup> See page 395 of the Journal.

(5) The diathesis may be latent from lack of circumstances awakening it into existence, as in the case of those leading lives of luxury and ease.

(6) The absence or suppression of the emotional temperament may retard, or altogether avert, the final catastrophe.

#### REMOVAL OF THE UTERINE APPENDAGES.

DR. A. P. DUDLEY presented the ovaries and tubes of a patient, the wife of a physician, which he had removed that day for a chronic inflammatory condition. It was such a case, he said, as would formerly have been supposed to be due to pelvic cellulitis; but a year's continual and faithful treatment had entirely failed to remove the difficulty, and no pelvic cellulitis whatever was found when the abdomen had been opened. The left ovary, in addition to being in an inflamed state, was markedly prolapsed, while the Fallopian tube on that side, also greatly inflamed, was bent downwards, with its fimbriated extremity adherent to the ovary and the tissues adjacent. Dr. Dudley had hoped to be able to save the right ovary; but the condition of the ovaries and tubes on both sides was found to be one in which acute attacks of inflammation were continually liable to occur, and in which the removal of all the uterine appendages offered the only hope of permanent cure. During the past year he had indeed cured the patient of two such inflammatory attacks, and this process would have gone on indefinitely as long as the organs remained in the body.

#### VENTRAL HERNIA; INTERMITTENT DIABETES.

DR. J. W. S. GOULEY related the history of a case, the pathological specimens from which Dr. Frank Grauer, of the Carnegie Laboratory, was to have presented, with a report of his microscopical examination. Dr. Grauer, however, was unable to be present. The patient was a lady, seventy-two years of age, who suffered from ventral hernia for more than twenty years, and he said it was the longest ventral hernia that he had ever seen. She had also been diabetic for at least thirteen years, and the form of glycosuria with which she was affected was that which the French term intermittent diabetes. For considerable periods at a time the urine would be entirely free from sugar, and at these times it would be loaded with urates and uric acid. The urine, which was sometimes passed in the most enormous quantities, was exceedingly irritating, and the patient suffered greatly from an eczematous affection of the vulva, and also from abscesses of the vulva and perinæum. At one time she also had a very large carbuncle on one hip; but she made a good recovery from this. Six weeks before her death she had an acute attack of bronchitis, from which she also recovered. Shortly after her recovery from this, however, she exposed herself to the draught from an open window, and this brought on another attack of general bronchitis. Although her vitality was very great, she was unable to stand this second attack, and died in the midst of it from exhaustion.

At the autopsy the hernial sac was found to consist of nothing but skin, and that was very thin. Dr. Gouley had always opposed operative interference in her case, and the condition of affairs found after death showed how unavailing any operation would have been. The sac contained the entire intestinal canal with the exception of the duodenum, the caput coli, and the rectum, and therefore it could not possibly

have become any larger than it was. The diameter of the neck of the sac was no less than nine inches. The liver was apparently normal, except that a small portion of the anterior border of the right lobe was sclerosed. There was also marked sclerosis of the spleen and of both kidneys. During life, however, there was no evidence of this condition presented by the urine; which was several times examined with great care by Professor Flint. The pulmonary tissue was normal, but there were present the lesions of acute bronchitis, extending to the smallest ramifications of the bronchial tubes. The heart presented calcareous degeneration of some of the valves, together with old mitral stenosis. The sclerosis of the spleen and kidneys was therefore amply accounted for.

DR. FLINT remarked that this case, which he had seen in consultation with Dr. Gouley, presented some points of extreme interest to him. This intermittent diabetes was a variety of the disease which he had seldom observed, and in regard to which he had formerly been somewhat sceptical. There could be no doubt, however, that this was a truly intermittent case, and not one of those instances, of which he had seen quite a number, in which the sugar disappears from the urine for a time after the patient undergoes a moderate restriction of diet. The case was of great interest, again, as regards the matter of diabetic coma. The patient at no time exhibited the slightest tendency to coma, but retained consciousness perfectly up to the last. She was unable to dislodge the mucus accumulated in the bronchial tube; and died simply of exhaustion.

Dr. Flint then referred to another case of diabetes, which he had recently seen in consultation with Dr. Frederic Dennis. The patient was a lady, seventy years of age, who had had diabetes for seven or eight years, which was by no means of an intermittent character. It was, on the contrary, persistent, and was attended with nearly all the typical symptoms of the disease. The case had been under the care of Dr. Lusk for some time, but was consigned by him to Dr. Dennis, on account of the fact that one of her feet became affected with gangrene. She was placed by Drs. Dennis and Flint on a strict anti-diabetic diet, and as she had been taking a very large quantity of milk daily, this was stopped. In addition, she was ordered three drops of Clemens' solution of arsenic of bromine, three times a day; and, under this régime, the improvement in her condition became very marked. The quantity of urine passed *per diem* was reduced from 110 ounces to 50 ounces, and the sugar was eliminated from it. The condition of the foot also improved for a time, but the gangrene afterwards extended, and the patient finally died of exhaustion. In this case, also, the mind remained perfectly clear to the last, and there was not the slightest approach to anything like diabetic coma.

Dr. Flint went on to say that, during the last two or three years, he had accumulated records of about ninety cases of diabetes, and that he had taken unusual care in following them up. Some of the patients had died under his observation, but he had never yet met with a single instance of diabetic coma. He had, however, records of cases, seen by him at one time or another, who had died under the care of other physicians, and who were reported by them to have been the subjects of diabetic coma. In this connection, he related the case of a very wealthy lady, to whom the

restraint of the restricted diet ordered for her eventually became intolerable, and who, on leaving for the country, announced her intention of trying a moderate indulgence in a general diet for a time. He afterwards learned that she had died in diabetic coma. He also knew another case in which the patient died of diabetic coma, after indulging in a prolonged "sugar debauch." Still another had died in the same way, after going to Carlsbad. During the journey to that resort she had lived upon an unrestricted diet, and he had been informed by her physician that, when she arrived there, she was in a practically hopeless condition.

The idea had been expressed in certain quarters that the restriction to anti-diabetic diet tended to produce diabetic coma, but Dr. Flint's experience was directly to the contrary of this. So far from its leading to this condition, he was convinced that it was extremely rare for patients to die of diabetic coma while they were living on a strict anti-diabetic diet; and he believed that this restricted diet actually prevented, or tended to prevent, diabetic coma. This condition was apparently due to the presence in the blood of some poison, which the kidneys were unable to throw off; and it was noticeable that when the coma came on, the sugar disappeared from the urine. He was at present engaged in a series of investigations upon this important subject, and hoped, at no distant date, to be able to ascertain certain facts which might, perhaps, throw some light upon it. In conclusion, he made some remarks upon the neglect of patients to carry out the anti-diabetic diet. It was this which had brought the method into bad repute, and he thought that physicians, as a rule, did not pay sufficient personal attention to the regimen of their cases. It was very important that this should be made as pleasant as possible for the patient, and efforts should constantly be made to tempt his appetite.

DR. CHARLES A. LEALE presented samples of two

#### NEW ANTISEPTICS AND DISINFECTANTS,

which he had tested, with satisfactory results, in his own practice. The first of these was glycozone, which consists of chemically-pure glycerine, with four volumes of ozone. It was an entirely odorless fluid, and it effectually destroyed all bad odors. It was thus a very valuable application for cases of offensive cancer. The other agent exhibited was solution of peroxide of hydrogen, which, he said, constituted a most admirable substitute for Labarracque's solution of chloride of lime, which was very offensive to many individuals. Diluted with water, ten parts to one, it could be used in all cases for which the latter was employed; and, like the glycozone, it was entirely odorless and colorless.

### Recent Literature.

*Monthly Nursing.* By ALFRED WORCESTER, A.M., M.D. 16mo. pp. 250. Boston: D. W. Mason, 1886.

This book is based on the instruction given to nurses at the Boston Lying-in Hospital, where the author was house-physician in 1883, and is the best manual on monthly nursing with which we are familiar. It is admirably written, the style is clear and crisp, and the teaching thoroughly sound. While the book will do much, we believe, to dignify her calling

in the estimation of every nurse who is fortunate enough to study its pages, it will not instill an exalted idea of her own importance; on the contrary, while the nurse is impressed with the responsible nature of her duties, she is taught to pursue her calling with becoming humility and with a spirit of loyalty to the medical attendant, whose lieutenant she is.

The first chapter, on Preliminaries, is replete with good advice concerning the nurse's health, dress, personal habits and conduct, and various minor, though important, matters in respect to her relations to the patient and the patient's family. Subsequent chapters impart such information concerning parturition as it is necessary for the nurse to know, and appropriate instruction as to her duties during labor and convalescence: the care of the baby also receives adequate attention. Chapter IX, on Emergencies, is a valuable one; and Chapter X, Odds and Ends, imparts much useful information, including clear instruction as to the proper records a nurse should keep for the use of the physician and her own improvement. The appendix contains a number of recipes for preparing various delicacies for the sick room, and a glossary of medical terms.

On page 124, footnote, in describing the double Y bandage for the support of the breasts, the author attributes the invention to Drs. Kingman, Otis and Hayward, former house-physicians of the Boston Lying-in Hospital: we understand, however, that the credit of this useful appliance, which is still used at the Hospital, is due entirely to Dr. Hayward. We regret that the author has failed to incorporate in his book more extended instructions concerning the use of antiseptics; but we have no doubt this defect will be remedied in subsequent editions, which we hope it will become the duty of Dr. Worcester to prepare.

*Diseases of Women. A Handbook for Physicians and Students.* By DR. F. WINCKEL, Munich. Translated by J. H. Williamson, M.D. Edited by Theophilus Parvin, M.D. Philadelphia: P. Blakiston, Son & Co. 1887.

We give a hearty welcome to this translation of "Winckel's Handbook of Diseases of Women." His reputation as an accurate observer, an indefatigable worker, a good pathologist, and a progressive yet conservative man are well sustained by this, his latest and most important work.

Its chief merits are the natural results of the characteristics of the man. As an acute and accurate observer he has let nothing that has come within the sphere of his activity escape him, and the result is a treatise on gynecology which is very complete. While giving in the main due prominence to the more important and commoner affections, he has not neglected to mention the very rare and even isolated cases of obscure diseases. Starting with diseases of the vulva in the opening chapter, he successively treats of diseases of the vagina, uterus, tubes, ovaries, ligaments, peritoneum, pelvic connective tissue and breasts, thus rounding out and completing the whole subject. To condense so much in a work the size of this one, has necessitated careful pruning, and a great deal of unnecessary matter has been left out. Descriptions of instruments and different forms of pessaries, histories of cases, and long descriptions of operative procedures which differ only in unessential points, are conspicuous by their absence.

A larger part is devoted to the pathology of the subject than is usually the case. This constitutes its chief value, for it meets a decided want. No other book to our knowledge presents so full an account of the results of recent pathological research in this department.

Winckel is eminently conservative, especially in the matter of operative treatment. At the same time he is free from prejudices, and holds himself open to conviction. Such an attitude on the part of one who is writing a book for "physicians and students," is certainly a wise one.

It would be impossible to read so comprehensive a work, and not find some ground for criticism. There is much less than usual in this book, however. His acquaintance with current literature on the subject of gynecology is very extensive. It is, naturally of course, mainly German, yet it seems as if he scarcely gave American gynecologists credit for their share in the progress that has been made. It would add value to the work if more complete references were given to authors and works cited. His descriptions of plastic operations on the vagina are brief, and in the absence of plates, not very clear. He has very little to say about the treatment of displacements with pessaries, and dismisses Emmet's operation for laceration of the cervix with a single short paragraph under the head of endometritis.

For so large a work, the number of plates is rather small; but it is a pleasure to see so many original ones, many of them drawn from actual pathological specimens.

The book will be a valuable one to physicians, and a safe and satisfactory one to put into the hands of students. It is issued in a neat and attractive form, and at a very reasonable price (three dollars).

*Drug Eruptions. A Clinical Study of the Irritant Effects of Drugs upon the Skin.* By PRINCE A. MORROW, A.M., M.D., Clinical Professor of Venereal Diseases, formerly Clinical Lecturer on Dermatology in the University of the City of New York, etc. New York: William Wood & Co. 1887.

This is a most useful book, one long needed. It is only within a few years that attention has been called to the subject of dermatitis medicamentosa, and although there have been many observations published concerning the irritating effects of individual drugs upon the skin, some of them of great value, there has been no general and exhaustive treatise before this. Indeed, it may be said that observers of sufficient dermatological skill to recognize the nature of such cutaneous disturbances were lacking until recently. As the author well puts it: "When the enormously large number of cases of drug eruptions which have been recently reported is contrasted with the comparatively few formerly recorded, it is evident that a prolific cause of cutaneous disorders long escaped recognition."

Disorders of the skin produced by the internal administration of drugs, are now designated by the title dermatitis medicamentosa, while the term dermatitis venenata signifies such disturbances as are caused by the action of external irritants. The title adopted by Dr. Morrow is a more general one, and includes, as employed by him, all inflammatory affections of the cutaneous tissues, which result from the internal and

external use of "drugs." Eruptions produced by the first of these causes he divides into two classes: (1) the ordinary forms, which he regards as an expression of the specific, physiological action of a drug upon the cutaneous tissues, and (2) anomalous forms, which he considers to be observations of the drug's normal action. Dr. Morrow is a disbeliever in the commonly accepted theory that the inflammation in dermatitis medicamentosa is due to the direct local action of the drug upon the cutaneous tissues during the process of elimination through the glands of the skin. He discards the results of some observers who have reported the discovery of irritating substances in the cutaneous glands, iodine for example, after their internal use, chiefly upon the failure of other investigators who fail to find them. In view of the conflicting character of such positive and negative results, this factor can hardly be excluded from the etiological possibilities. It is in the sphere of the nervous system that he looks for the explanation of these phenomena, a part of which he attributes to the irritating effects of the drug in the blood upon the vaso-motor centres, and a part to its direct action upon the peripheral nerves.

After introductory chapters on general characteristics, etiology, pathogenesis, diagnosis, and treatment, the author proceeds to describe, following an alphabetical arrangement, the inflammatory effects of all drugs upon the skin, which have fallen under his own observation, or of which an exhaustive search through medical literature of recent years, receives mention. In connection with the careful analysis of the varied effects of these agents upon the cutaneous tissues there is also given in most instances an elaborate account of the tests for their presence, or that of their modified forms, in the urine, of great value in a diagnostic point of view. The number of drugs capable of producing such irritation upon the skin by internal use or external contact thus treated of, is sixty. The action of some of them in this direction is of course very trivial and of infrequent occurrence, but others from their enormous use in medicine and the great frequency and variety of their mischievous effects demand the serious consideration of the practitioner. This they have received in due measure from the author, and his treatment of the most important subjects, as the action upon the skin of arsenic, bromine, chloral, cinchona, iodine, etc., is exhaustive and admirable. Inasmuch as the tissue changes produced by such irritants range from the most fugitive expressions of simple hyperemia to grave forms of destruction and hypertrophy even, and closely simulate many well-characterized cutaneous affections, it is evident that it requires the skilled dermatologist to present the subject in a proper form for the practical needs of the general physician. Nor should the latter fail to take advantage of such special studies, for errors are constantly arising for lack of such knowledge on the part of the latter, who often fails to recognize that a dermatosis occurring in the course of some disease under his care is the direct result of his own remedies.

The book presents a general good appearance, and is illustrated by a well-executed colored frontispiece of a remarkable case of dermatitis produced by iodide of potash. It is furnished also with a very complete and valuable bibliography.

—A physician, Dr. Baxter, has been elected speaker of the Ontario Legislature.

THE CAUSES OF MALIGNANCY IN SYPHILIS.

LIKE other diseases, syphilis presents a great variety in the severity of different cases. Some cases are benign: their manifestations are superficial and of short duration, and their tertiary lesions, if they appear at all, come on after many years of perfect health. Other cases are malignant: the cutaneous manifestations ulcerate, they succeed each other in a fashion almost continuous, and the general condition of the patient is profoundly altered; the late manifestations occur at an early period, and are of a severe, and perhaps fatal, character.

The malignancy of certain cases may be explained, either by a special germ which bears in itself the principle of special gravity, or the character of the individual disease is determined by the soil upon which the germ is developed. The doctrine which refers the gravity or benignity of the disease to the source of contagion explains all easily; but the generality of pathologists believe, to-day, that if a syphilis is severe, it is so by virtue of circumstances personal to the patient. Syphilis is syphilis, exactly as small-pox is small-pox. Cases vary in gravity in the same epidemics, and in the same family. Confrontations show that the transmitted syphilis may vary very greatly in gravity from the original. Cases of husband and wife, who must in all human probability have received their disease from the same stock, differ very greatly in the experience of most physicians. The doctrine of different viruses was strongly upheld by the *Revue Médicale* of March 27, 1886. In the view of that journal, there are attenuated viruses. Syphilis always resembles the parent stock, and there are certainly stocks so attenuated, that, even in old men and the tuberculous, they produce only very benign cases. Such it believes to be the history of all virus, and, in this way, it explains the gravity of the syphilis of seaports, and of certain countries. "Is it not evident," it inquires, "that the diathesis has become attenuated since the commencement of the century? Why, if not because that, transmitting itself from subjects

treated, to other subjects who are also treated, before communicating it themselves, its principle becomes less and less active? In prognosis, then, it is necessary to take into account the form of disease communicated." The gravity of syphilis in seaports, if one may judge other ports by Boston, remains to be established. The diseased may be divided into two categories: the seafaring population, and the land abiding. The sailors present a noticeable number of grave cases of syphilis, as compared with the dwellers on the land. Such a gravity would be explained by the importation of an unusually grave form of disease, and such an explanation would be accepted by the sailors themselves. They believe the Chinese pox, for instance, to be much more severe than other forms, but the character of the soil is to be considered. As a whole, the merchant seamen of the present day, though an exceedingly interesting, are not a thrifty and care-taking class, but rather rum-loving, improvident, and careless, exposed to all sorts of vicissitudes of weather, presenting, in fact, just the characteristics which, in others, we believe, lead to a malignant type. If the germ differs here, the soil differs also. In a clinical lecture during the past year, by M. Fournier, he pronounces himself strongly in favor of the invariability of the virus, and he mentions six different causes of malignancy,<sup>1</sup> whose existence he believes to be well determined: (1) Certain conditions of age. (2) Scrofulo-tuberculosis. (3) Alcoholism. (4) Malaria, which counts for much, probably, in the gravity of syphilis contracted in the colonies. (5) Hereditary or acquired predisposition. (6) One of the most important—the absence or the insufficiency of treatment at the origin of the disease.

One may say that syphilis is particularly grave at the two extremes of life: in the very young and the very old. This rule would apply, in the young, quite as much to the acquired as to the congenital form; so vaccinal syphilis in very young children results almost always in very grave, often fatal, accidents. After six months or one year, the prognosis of syphilis so contracted is entirely different. Acquired beyond fifty, the prognosis of syphilis is grave; beyond sixty, it is yet more grave, and the disease is characterized by, first, a tendency of the primary lesion to phagedena; second, of the eruptions to be profuse and general; third, early appearance of the tertiary accidents, like gummata and cerebral lesions; and fourth, and lastly, the tendency to a very marked reaction upon the general condition, a loss of appetite and of strength, a languor and enfeeblement, and prostration, followed by actual cachexia.

Scrofulo-tuberculosis has, according to Fournier, such an influence upon syphilis, that its action has never been disputed. In the scrofulous, syphilis has a tendency to take on the suppurative, ecthymatous, impetiginous, rupial forms. It is among them that one sees the precocious, malignant syphilide and the massive adenopathies, with multiple ganglions con-

<sup>1</sup> *Annales de Dermatologie et de Syphilographie*, 25 Mars, 1887, p. 204.

nected together, and becoming fistulous. These adenopathies may produce themselves at the time of the chancre, and differ decidedly from the *pléiade* of Ricord. They constitute the syphilo-strumous bubo. In place of the posterior cervical ganglion, for example, one finds a ganglionic chaplet, extending from the mastoid to the clavicle. Ocular accidents are also frequent; in the articulations, pseudo-white-wellings produce themselves; finally, it seems that the scrofula directs the syphilitic lesions towards the mucous membranes of the larynx, pharynx, and nasal fossæ.

It must be added, too, that in these conditions, syphilis often occasions grave troubles of health, ending rapidly in cachexia. In addition, the association of scrofula and syphilis ends in creating singular hybrid types, which recall, by the ensemble of their characteristics, the two maladies. Syphilis reacts upon scrofulo-tuberculosis by aggravating it. It is certain that, in subjects predisposed to tuberculosis, syphilis provokes the development of that disease in the same way as other causes, like fatigue, grief, or poverty.

Alcoholism has a very marked, though not a constant, influence upon the gravity of syphilis, and it acts in four different modes: First, it predisposes to grave and precocious forms of the syphilides, which do not usually appear until after the lapse of many years. Alcohol has an influence upon all the dermatoses, and it is not astonishing to find that influence in syphilis, and it is often so marked, that one can diagnose alcoholism by the aspect alone of the lesion. Alcoholism also favors the production of those forms in which the syphilitic manifestations succeed each other in a fashion almost continuous. It favors again, those cases which act upon the general health, and can, in little time, cause a veritable cachexia. Alcohol, at last, predisposes to cerebral syphilis. It figures largely in the antecedents of those thus afflicted, and it is to its influence that are due the precocious cerebral cases that appear in the secondary period, and even in the first year of the disease.

But of all the causes of gravity in syphilis, the most common, and, at the same time, the most active, is poverty. The syphilis of the poor is often fruitful in immediate accidents, more or less severe, such as ulcerating, confluent syphilides, intense alopecia, pains, ophthalmias, and, above all, accidents of a general order — asthenia, anæmia.

Syphilis is infinitely less grave in the easy classes. M. Fournier makes an exception for the syphilis in those whom one calls the *viveurs* — men of the world — the inactive, the idlers, the useless. They are exhausted by the dissipations, the nights turned into day, and the fatigues of a worldly life; and this exhaustion brings the same consequences as actual want. In gamblers, cerebral syphilis is particularly common, as also among the men of the stock exchange, financiers, and actors. Nervous overwork constitutes one factor of gravity for syphilis, in directing its localizations upon the brain and the cord.

As to the absence or insufficiency of treatment as a cause of gravity in syphilis, M. Fournier remarks that the enormous majority of cases of grave tertiary syphilis (nineteen out of twenty) occur in those who have not been treated, or who have been only insufficiently treated. It is not with a treatment of some weeks that syphilis is cured in a definite fashion. It needs a treatment prolonged and methodic, and few persons submit to it. Moreover, many cases of syphilis are unrecognized until some tertiary accident sends the sufferer to the doctor.

#### THE TREATMENT OF ANEURISMS.

A CASE of aneurism of the innominate, reported in this issue of the JOURNAL, in which various recognized methods of treatment—rest, diet, pressure, the internal exhibition of iodide of potash in increasing doses for a long time, and subsequent successive ligation of the carotid and subclavian arteries—were all faithfully resorted to without averting a fatal issue, notwithstanding the fact that the patient was in many accounts an unusually favorable subject, suggests a brief consideration of the treatment of aneurisms as practised at the present time.

Dr. I. Burney Yeo, in his recent lectures on Clinical Therapeutics, affirms that one of the most remarkable gains in the treatment of disease in recent years has been the employment of large doses of iodide of potassium in the treatment of internal aneurisms. When he began the use of this remedy in these affections, his results were disappointing, and he found many of his colleagues equally sceptical as to its utility, which is scarcely to be wondered at from the size of the dose given. But in the year 1877, on the occasion of the meeting of the British Medical Association at Manchester, he was fortunate enough to see in the Infirmary of that city a number of cases of thoracic aneurism, which had been collected together by Dr. Simpson, for the purpose of showing members of the Association the value of the iodide of potassium treatment of such cases. It was a remarkable series of cases, and the results were excellent, but instead of giving these patients such small doses—five grains three times a day—as Dr. Yeo had been in the habit of prescribing, the Manchester physician was giving twenty to forty grain doses three times a day. As soon as Dr. Yeo began using these larger doses, he saw admirable results follow. On inquiring into the *modus operandi* of the curative action of iodide of potash in internal aneurisms, he found that only a small proportion could be regarded as syphilitic, and even in these cases it was difficult to understand how the iodide did good. Another suggestion was that the iodide increased the coagulability of the blood; but post-mortem examinations seemed to show that the process of cure was obtained chiefly by “some peculiar action on the fibrous tissue, causing thickening and contraction of the walls of the sac.”

It had been noticed clinically that in some cases under the influence of the iodide, the pulsations in the aneurismal sac and throughout the arterial system, were much diminished in force, and this was referred to a reduction in the intra-arterial blood-pressure, brought about by the action of the drug.

Balfour was the first to bring iodide of potassium prominently to notice as a remedy for aneurisms. His doses were large: thirty grains three times a day for months. The effect of iodide of potassium is, he thinks, to produce diminution of the cardiac force and of the blood-pressure, and secondarily, diminution of the size of the sac, and thickening of its walls. Any coagulum present, Dr. Balfour thinks, is accidental, or at least not dependent on the action of the iodide.

Notwithstanding these favorable endorsements and the numerous reports of good results and improvement under the iodide, we are inclined to the opinion expressed by Strümpell, that but little action of lasting character can be expected on an aneurism from the use of internal remedies, although we are ready to accept Flint's injunction that the iodide should be faithfully tried in cases of thoracic aneurism. The influence of the drug may be increased if accompanied by a strict application of Tufnell's method of absolute rest in the recumbent position and a strict limitation of food and drink—ten ounces of solid food and eight of liquid being recommended as the limit to be aimed at. The patients possessed of the philosophy and self-control to submit honestly and persistently to such a regime are, however, rarely encountered.

Blood-letting as advocated by Valsalva is no longer practised, and it is also recognized that the withdrawal of food and drink beyond a certain point, which should be ascertained in each individual case, causes anemia, weakness, irritability of the heart, impaired nutrition of the arterial walls; all of which certainly do not favor the formation of coagula.

Turning now to the operative processes, we have, in addition to pressure and the ligature—two well-established methods where the situation is favorable—galvano-puncture, and the introduction of foreign bodies such as fine wire, horse-hair, catgut, silk, etc.; the last two methods are still on trial, and have been practised in too small a number of cases to allow of very definite conclusions as to modes of application or as to probable results. The introduction of foreign bodies in particular has been practised, hitherto, we believe without exception, in rather desperate cases.<sup>1</sup> Galvano-puncture has occasionally been followed by cure in suitable cases, more often by disappointment and sometimes by inflammation of the sac and speedier rupture. It has also been accused of giving rise to emboli and regarded as dangerous for that reason. Both of these methods are well presented in a report of two cases by Dr. Robert Abbe, before the New York Surgical Society, incorporated in a paper<sup>2</sup> on aneurisms treated by the introduction of catgut, or

of wire, with electricity. He considers the introduction of foreign bodies as only indicated in the class of aneurisms springing from the aorta or its greater branches, not amenable to ligature and irresponsible to medicine, diet, or rest. Fifteen cases of the use of wire, silver, iron or steel, have been reported, two of which have been followed by recovery; in only two of the cases was there any trouble from emboli, and in one of these the origin was doubtful; eight of the cases gave autopsies, all except one showing coagulation. Barwell, Roosevelt, and Abbe have applied electrolysis after inserting the fine sterilized wire through a small insulated canula. All of these fifteen cases were regarded as desperate, and the fact that obliteration of the sac was produced in two large aneurisms of the abdominal aorta—in neither of which electrolysis was used—shows that the method is, at least, worthy of further trial and attention.

With regard to distal ligature in aneurism of the innominate, Barwell's position, that simultaneous ligature of the subclavian and carotid, when not contra-indicated, is preferable to consecutive ligature, is now generally accepted. A recent successful case, in which the operation was performed by Dr. John Ashhurst, was reported by Wharton.<sup>3</sup> He finds that consecutive double distal ligation has been practised and reported in eight cases of supposed innominate aneurism, with three recoveries and five deaths, there being temporary improvement in one of the fatal cases. Of thirty-two cases of simultaneous ligation recovery followed in twelve, death in sixteen, temporary improvement in four. The ratio of recoveries is about equal, but the number of reported simultaneous ligations is considerably larger.

#### MUSCULAR ATROPHY CONSECUTIVE TO LESIONS OF THE JOINTS.

The wasting of muscles in consequence of injury of joints in the vicinity has long been known, and was first remarked by John Hunter, who calls attention to it, under the head of sprains and dislocations.

Bonnet, in 1845, indicated muscular atrophy among the complications of sprain; and Roux, in the same year, mentions atrophy of the deltoid as following puncture in cases of scapulo-humeral hydrarthrosis. Gosselin also, in 1859, described the muscular atrophy consecutive to fractures of the long bones. Duchenne, of Boulogne, reports a case of sprain of the knee, with considerable swelling of the joint, which was followed by wasting of the thigh muscles, so that extension of the leg on the thigh became impossible.

Valtat, who has written a very complete treatise on the subject, has produced inflammation of the joints in animals, and has seen notable atrophy follow in the muscles above and below the joint affected. The atrophy comes on in less than a week after the injury, whether the lesion be experimental or accidental,

<sup>1</sup> An account of previous cases may be found in this Journal, Vol. cxii., p. 354.

<sup>2</sup> Medical News, April 9th, p. 397.

<sup>3</sup> Proceedings College of Physicians, Philadelphia, March 2, 1887.

and is more apt to follow arthritis in young than in old subjects. It disappears rapidly when the joint-inflammation subsides.

Vulpian, who discusses the subject exhaustively in his recent work on "Nervous Diseases," attributes the pathogeny of this atrophy to "a special modification of the cells of the anterior gray horns of the spinal cord—a modification brought about by irritations emanating from the peripheral parts that are the seat of the injury, and whose final result is an enfeeblement of the trophic influence of those motor cells."

The same explanation applies to the muscular atrophy sometimes accompanying neuralgias, burns, wounds of nerves, etc.; and thus it will be seen that the pathogeny is essentially the same in these cases, as in atrophic spinal paralysis of infant and adult life, a diminution or impairment of trophic influence being the cause, although (it must be remarked) the spinal affection in the atrophy of arthritis, neuralgia, etc., is functional, rather than organic.

#### MEDICAL NOTES.

—It is stated by the *Medical Press*, on the authority of Dr. Grawitz, an assistant of Professor Virchow's, that in as many as one-third of the cases of so-called muscular rheumatism which have been examined *post-mortem*, the presence of the *trichina spiralis* has been demonstrated. In many of these cases, the parasites must have been present in the muscles for many years.

—Surgeon-Major Moore, of the English Army, the originator of the present ambulance system, has become blind and has been obliged to retire on the lowest rate of pension. The secretary for war, while admitting that the case was deserving of sympathy, declined to accede to any request that might be made a precedent for an increase of pension. It is not alone republics that are ungrateful.

—Quarantine has been established, except at Alexandria, by countries along the Mediterranean for ships arriving from Sicily. At Malta a stringent quarantine has been established against Sicily. Passengers arriving from other Mediterranean ports are obliged to produce a consular certificate that they have not been in Sicily for twenty-one days, before being allowed to land.

—The consular reports published by the Marine Hospital Service, April 21st, show that up to March 6th, there had been no appearance of cholera in Peru. Some cases had been reported on the eastern interior frontier of Bolivia, doubtless proceeding from the Argentine Republic, and energetic measures were being taken to prevent the spreading of the disease. Cholera, in Chili, was rapidly diminishing at last reports, early in March: a report of its appearance in Mexico has been officially denied by telegraph.

—The report comes from a Russian source, of a curious case of self-castration: A tall, powerfully-built, married peasant, twenty-nine years of age, who

had been subject to epileptic attacks, and had become morose, silent, and fond of religious literature, while reading one of his favorite books, suddenly, with a single pull, and without a cry, tore away his scrotum, together with the testes. Then, rising from the bank where he was sitting, he quietly handed the avulsed parts to his mother, who was near, with the words: "Take that; I do not want it any more." On admission to the hospital on the following day, there was found a lacerated wound as large as a man's hand, with an uneven base and irregular edges. The general condition was good; there was neither pain nor constitutional disturbance. The wound healed rapidly and well. A similar case had been previously reported by the same physician, the patient mutilating himself in this way while suffering from delirium tremens.

—The French developers of hypnotism seem to have carried their science to a point of supersession of the decalogue, and to have set their subjects on a plane exempt, even, from the civil law. Thus the Paris correspondent of the *Lancet* describes the history of a patient under the care of M. Mesnet, as related by him at a recent meeting of the Academy of Medicine: A young man, nineteen years old, whose mother was the subject of hysteria, had had fits of somnambulism from the age of fourteen. These became so frequent, by day as well as by night, that he was discharged by his employers. Besides the fits of sleep, he has general anesthesia and analgesia, together with complete loss of taste and smell. At the end of last year he was admitted to the hospital. As a matter of course, he was at once utilized for experiment in hypnotism, and was found to be easily induced into the state of "hypnotic fascination" by the magnetic stare, and as easily awakened by being blown upon the face. It was interesting, says M. Mesnet, to ascertain whether this young man was accessible to post-hypnotic suggestion. Having been sent to sleep as usual, he was imperiously ordered to take the watch of one of the students on the following day, and then to endeavor to make his escape. At the appointed time, which was the usual visiting hour, he was seen to look contemplatively at the student's chain; he soon became fascinated by the shining links, and, after several struggles against the suggestion, he could resist no longer, and, detaching the chain, made an attempt to escape. When awakened, and the watch taken from his pocket, he was unable to account for its possession, but protested his innocence and burst into tears. This shows, says M. Mesnet, that a thief or assassin who cannot explain his acts, and declares he has no recollection of them, may be an unconscious agent. Although a magistrate will not believe his negation, he may have no knowledge of what he has done. Prosaic persons may hesitate to accept M. Mesnet's conclusions, but the fascinating action of watch-chains is now placed beyond doubt; and those who are affected with this variety of hypnotism in its chronic form will appreciate his soundness of observation.

## NEW YORK.

—An anonymous gift of \$10,000 has been made, through Mr. George I. Seney, to the Methodist Episcopal Hospital, of Brooklyn. This is an institution which was founded by Mr. Seney, but, on account of his failure in business a few years ago, he was unable to carry out his plans in its behalf.

—The office furniture and fixtures of the Homeopathic Mutual Life Insurance Company have been attached by the sheriff, on the suit of certain policyholders, who claim that the company is insolvent. In the spring of 1886, the Superintendent of Insurance of Massachusetts discovered that its capital was impaired, and peremptorily ordered it to withdraw from business in the State.

—Much complaint having been made of the discomfort and injury to health resulting from the dusty condition of the streets during the past spring, the Mayor has commenced an enforcement of the ordinance prohibiting the sweeping of dirt from stores and dwellings into the street; and, at six o'clock one morning last week, no less than 283 arrests were made by policemen in citizens' clothes, the defendants being fined \$1 and \$2 each at the police courts.

### Miscellany.

#### CATARACT INDUCED BY THE VIBRATIONS OF TUNING-FORKS.

DR. S. TH. STEIN, in order to examine the functions of the cochlea, as reported by the *Lancet*, acted on the eyes of very young porpoises, both in the unimpaired state and after the ears had been destroyed, by means of the vibrations of tuning-forks of different pitches. Cataract was produced in both classes of experiments. In the entire animals, continuous subjection to the action of a high-pitched tuning-fork induced cataract in from eighteen to twenty-four hours, while a tuning-fork vibrating 100 in the minute produced the same effect in twelve hours. In animals whose ears were destroyed, the cataract was much more quickly induced by the tuning-fork, some two or three hours being then sufficient. Dr. Stein's theory is that the condition of the lens is affected by the giving off of heat from the body, and that this is altered by the vibrations, the perception of sound again tending to retard the development of cataract. The members of the Moscow Medical Congress, before whom Dr. Stein related his experiments, did not appear inclined to accept his theories, and Professor Khodin remarked that it was not an uncommon thing for young porpoises to be born with cataract. To this, however, Dr. Stein replied that the cataract produced by his tuning-forks passed off after a time, and could then be re-induced by the same method.

#### DISTANCE-SUTURE OF NERVES AND TENDONS AND SOME APPLICATIONS OF ANIMAL GRAFTS.

GEORGE ASSAKY (Lille), reported to the French Congress of Surgery, the result of certain experiments made by himself and M. Fargin on the above

subjects, which are thus given in the *Annals of Surgery*, April, 1887. This suture consists in connecting by long suture threads the two ends of parts, the apposition of which is unobtainable. The first suture of this kind was made by Benjamin Anger for the tendon of the extensor minimi digiti; the two ends were nine cm. apart, but traction reduced the distance to two cm., and he connected them by a silver suture with a satisfactory result. Gluck substituted catgut in two cases with satisfaction. With M. Fargin, the author has applied distance sutures; the tendons regenerated along the threads are always stronger than those spontaneously regenerated; the number of tendinous fasciculi is greater. This operation is clearly indicated when apposition is impossible; it is more particularly applicable to tendons without a sheath.

They also made experiments upon the application of distance sutures to nerves. They interposed between the two ends of the divided nerves fragments of tendon, muscle and spinal cord. The mechanical conditions had great influence in the regeneration of nerve tissues; catgut gave the best result; silk threads remained indefinitely in place without taking part in the nerve regeneration. In every case examined microscopically, the cicatrix contained connective tissue, but also a great quantity of nerve fibres. This operation then seems to be indicated when the apposition of the two ends of the divided nerve is impossible, and also after certain surgical operations, the ablation of a neuroma, for example.

It was shown by their experiments that tendon may be grafted to animals of the same species and of different classes. These facts have already been applied to man twice. M. Peyrot has obtained in one case the transplantation of a dog's tendon and in another a cat's tendon. All attempts at nerve grafting completely failed; in certain cases there was no elimination, but it could be ascertained that the transplanted nerve-tissue did not enter into the regeneration.

#### THE PREVENTIVE INOCULATION FOR YELLOW FEVER.

THE United States Marine Hospital Service published, in its weekly abstract of sanitary reports, under date of April 14th, 1887, a despatch from the United States consul at Maricaoibo, dated March 7th, in relation to the subject of inoculation as a preventive of yellow fever, with enclosed copies of letters from the Venezuelan consul at Cucuta, Colombia, and from Dr. Bustamante, of the same city, from which it is learned that "Dr. Urricochea, surgeon of the frontier battalion, inoculated, by way of experiment, and with good results, five of his soldiers. Twenty minutes after the operation the temperature gradually ascended to 40 C., accompanied with all the symptoms of yellow fever. This lasted forty hours, at the expiration of which the fever and all attendant symptoms had disappeared. This operation was effected in a place called Moras, three leagues from Cucuta, and where a body of troops is stationed, who have not come to this city for fear of the fever. At present, the inoculated soldiers are here, exposed to the action of the focus of infection. As in Moras, no case of the epidemic has as yet presented itself." Dr. Bustamante, in his letter, says, "as yet my labors in the field of inoculation as a preventive of yellow fever are only, it

may be said, mere experiments, which, although they may satisfy me with a well-founded hope of successful and complete result, cannot be of genuine utility until the best and most efficacious method is decided upon. I am thinking, however, of making an abstract of my observations, together with the method pursued, the results obtained, and everything that may be useful in the premises. For the present, I will confine myself to the statement that, in more than forty persons whom I have inoculated, a fever, with many of the characteristic symptoms of yellow fever, has presented itself; this fever, developed by inoculation, varying several tenths of a degree, and, in some cases, ascending to  $41^{\circ}$  C., but never presenting the most grave symptoms of yellow fever. The result of my observations permits me to state positively that the fever produced by inoculation is attended with no danger; and it is safe to inoculate, as I have already done, from children of two years of age to the oldest individuals. Many of the persons inoculated have come to this city, and in no case has the yellow fever attacked them, which gives me hope of a final result completely satisfactory. The municipality, assisted by the merchants, sent to Mexico, January 10th, a commission composed of two physicians, in order to study the inoculation of the fever."

#### THE METRIC SYSTEM.

PROF. OLBERG publishes in the "Pharmacist," a long and interesting article, assigning grave reasons why the present — which he calls "Anglo Saxon" system should be preferred to the metric system.

A writer in the *Scientific American*, gives his preference for the old system, and says:

"I have gone, this summer through the workshops of almost all the great countries on this side of the water, and have seen the practical use of the system that I have for so long a time condemned."

I have frequently asked engineers if they liked the system, and I will give the answer of one in Berlin. "We use it because we have to, and it is better to have some uniform system than the many measurements that formerly prevailed in the German States. We do not like the metric system because it has too small a unit, and the metre is too large and involves the use of too many decimals. When we consider the interests involved, it will be seen that the population now making practical use of the English standard is greatly in excess of that using by force, the French system. I am more confirmed in my opposition to the enforced adoption of the metric system in my country, and firmly believe that those countries that have adopted it are at a disadvantage (as compared with even the most imperfect of our systems)."

To show the opinion of doctors and druggists of the United States, Dr. A. C. Matchett tells the *Medical Brief*, "that a year since he asked for an expression of approval or otherwise of the metric system of weights and measures, from the medical profession and the druggists of the United States and found seventeen physicians and thirty-one druggists in favor of the system, and 3611 physicians and 2764 druggists opposed to it. The forty-eight wise men who wish for it have, however, made more noise than all the 6405 who do not want it. Leaving aside all argu-

ments, the majority, as it seems from the above statistics (and the majority always rule), say stick to the old system. Why try a system that was only made compulsory and used in a country that had such a multiplicity of measures, almost one to each province, that a general system had to be adopted in order to remedy the evil of varying local standards. Just as well to have adopted our system, for Sir John Herschel has pointed out that the polar axis of the earth is almost exactly 500,500,000 inches, and that the inch may therefore be considered quite as properly a national standard as the metre, and that the desirable correlation between volume and weight may be found in the fact that a cubic foot of distilled water weighs nearly a thousand ounces. By slight changes of the units this relation might be made exact, and the inch become equal to 1,500,000,000 part of the earth's polar axis; twenty-five of such inches making a cubic equal to the 1,10,000,000 part of the polar radius.

#### Correspondence.

##### TEN YEARS OF METRIC PRESCRIPTIONS.

( $10 \times 0.1 = 1.0$ )

SALEM, April 13, 1887.

MR. EDITOR.— Would it not be of interest if the enthusiastic pioneers of the metric movement, who advocated its adoption so cogently in the columns of the *JOURNAL*, a decade or so ago, should now report through the same medium to what extent the seed then sown has borne fruit? It will be remembered that at that time, or soon after, the *JOURNAL*, with the view of familiarizing and helping forward the cause, presented an epitome of the metric system in medicine, on the last page of each number, for a period covering several months, but the practice finally fell into desuetude, and for some years, or since the exposure of the *c.c.* fallacy, but little has appeared in print concerning the system.

In the following few lines, is embodied the writer's uneventful experience in writing metric prescriptions *exclusively*, for the past ten years (with the solitary exception of a receipt once given to a friend when in London).

His first one (April 23, 1877) was thus written:

Zinci sulph.	.	.	.	.	gr. 1	0.06
M. Aq. rose.	.	.	.	.	3	31.0

With a view to educate the apothecary up to the decimal point, this double method was continued for over a year on every prescription that was written.

This modification was then made — most of the reputable druggists of Salem and vicinity having, in the meantime, provided themselves with metric weights:

Zinci sulph.	.	.	.	.	0.05	5 centig.
Aq. rose.	.	.	.	.	30.0	30 grams.

But after the lapse of a few months the translation on the right was omitted, and the plan that prevails in Germany was adopted and continued to the present time. (In France, where the paternal oversight is so fully developed, the quantities of the ingredients of *les ordonnances* are ordinarily written instead of being expressed in decimals.)

Some thousands of prescriptions I have been written in the last ten years by the undersigned, and it is rather remarkable that none have ever been returned by a perplexed dispenser (excepting once or twice, when the quantities were inadvertently omitted) — a fact that speaks volumes for the progressive tendency of the American apothecary, or else for the ingenuity with which he adapts himself to unknown ways.

It must be confessed, that one conscientious but irascible

apothecary made a most violent onslaught on the writer, by letter. In it, he said, he should positively refuse to have anything to do with a system that was in direct violation with the laws of the land, and the general adoption of which would surely give rise to fatal accidents and much woe.

As a matter of fact, so far as is known, no mistakes or accidents have ever been traced to the writer's lawless method of ordering medicines.

The compilers of the last "United States Pharmacopœia" (edition 1882), indecreeing that measures of capacity should be expressed in parts by weight, doubtless did much towards familiarizing both physicians and pharmacists with the metric idea.

Not infrequently, patients on glancing at the prescription have recognized it as a decimal one and have ex-

pressed themselves favorably of the system. But not long ago, a bucolic female, after attentively examining a prescription, appended to the several ingredients of which were 1.0, 0.50, etc., asked if the figures indicated the cost of each article, for, if so, she could hardly afford to have the receipt prepared.

It is scarcely necessary to say that after a trial of ten years, in writing metric prescriptions and in recording cases of refraction after the decimal system, the writer is not inclined to return to cabalistic symbols, or to the inconveniences of vulgar fractions.

Allowing that the lineal standard is not exactly all that is claimed for it, perhaps the metre rests on a better scientific basis than does the old English inch, which represents the length of three barley-corns.

Very truly yours, D. COGIN, M.D.

Deaths reported 2,295; under five years of age 839; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fever) 388; acute lung diseases 387; consumption 364; diphtheria and croup 110; measles 37; diarrheal diseases 41; scarlet fever 27; typhoid fever 21; whooping-cough 15; cerebro-spinal meningitis 10; erysipelas five; malarial fever nine; puerperal fever nine. From scarlet fever, New York 13, Pittsburgh four, Philadelphia and Boston, three each, Baltimore two, District of Columbia and Milwaukee one each. From typhoid fever, Philadelphia eight, Baltimore four, Boston, District of Columbia and Lawrence, two each, Pittsburgh, Fall River and Gloucester one each. From whooping-cough, Baltimore four, New York and Philadelphia, three each, Milwaukee two, Pittsburgh, Providence and Lawrence one each. From cerebro-spinal meningitis, New York five, Milwaukee two, Richmond, Baltimore, and Springfield, one each. From malarial fevers, New Orleans six, District of Columbia three. From puerperal fever, Philadelphia and Pittsburgh, two each, Boston, Baltimore, Cambridge, New Bedford and Newton, one each. From erysipelas, Philadelphia two,

Richmond, District of Columbia and Providence one each. From small-pox New York five. Pittsburgh one case of small-pox.

Cases reported in Boston: measles 60, diphtheria 25, scarlet fever 22, and typhoid fever 15.

In the 19 cities and greater towns of Massachusetts, with a population of 949,534 (population of the State 1,941,463) the total death-rate for the week was 22.18 against 21.95 and 22.22 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,245,099, for the week ending April 2d, the death-rate was 21.6. Deaths reported 3,831; infants under one year of age 867; acute diseases of the respiratory organs (London) 417; measles 239, whooping-cough 105, scarlet fever 37, diphtheria 32, diarrhoea 32, fever 25.

The death-rates ranged from 14.6 in Brighton to 33.1 in Blackburn; Birmingham 18.6; Bradford 17.2; Hull 22.0; Leeds 23.1; Leicester 20.0; Liverpool 20.5; London 19.7; Manchester 28.7; Newcastle-on-Tyne 22.2; Nottingham 30.7; Sheffield 23.1. In Edinburgh 21.6; Glasgow 23.4; Dublin 31.3.

The meteorological record for the week ending April 16, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending Saturday, Apr. 16, 1887.	Barom- eter.	Thermometer.		Relative Humidity.		Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 16, 1887, TO APRIL 23, 1887.

**MOSKLEY, EDWARD B.**, captain and assistant surgeon. Ordered for duty at Whipple Barracks, Ariz. S. O. 89, A. G. O., April 18, 1887.

#### APPOINTMENTS.

**CHARLES E. WOODRUFF** and **JULIAN M. CARROLL**, to be assistant surgeons with the rank of first lieutenant, to date from April 14, 1887.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING APRIL 23, 1887.

**RUSSELL, A. C. H.**, passed assistant surgeon. Ordered to duty at Naval Laboratory, New York, May 2, 1887.

**HEFFNER, A. C.**, passed assistant surgeon. Ordered to Widow's Island, Me., to superintend building a naval hospital, wharf, and other improvements under instructions of the surgeon general of the Navy.

**WOODRUFF, CHAR. E.**, assistant surgeon. Resignation accepted to take effect April 8, 1887.

#### SOCIETY NOTICES.

**BOSTON MEDICAL ASSOCIATION.**—The Annual Meeting will be held at 19 Boylston Place, on Monday, May 2, at 4 P.M. Election of officers.

**WILLIAM D. HODGES, M.D., Secretary.**  
220 Clarendon St., April 25, 1887.

**SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION.**—There will be a meeting of this Section at 19 Boylston Place, on Tuesday evening, May 24, at 8 o'clock. Dr. S. J. Mixer will report a "Case of Tumor of the Breast." Dr. E. G. Brackett will make a communication on the "Experimental Value of Dow's Splint." Dr. E. O. Otis will read a paper on "Injuries of and Operations upon the Kidney."

**G. H. MONKS, M.D., Secretary.**

**BOSTON SOCIETY FOR MEDICAL OBSERVATION.**—A regular meeting of the Society will be held at the Medical Library, 19 Boylston Place, on Monday evening, May 24, at eight o'clock. Readers: Dr. A. F. Holt, "A Case of Acute Red Atrophy of the Liver." Dr. O. F. Wadsworth, "A Case of Recurrent Paralysis of the Third Nerve."

**CHARLES F. STRONG, M.D., Secretary.**

**SUFFOLK DISTRICT MEDICAL SOCIETY.**—The annual meeting will be held at 19 Boylston place, on Saturday, April 30, 1887, at 7.45 P.M. Papers: Dr. E. G. Cutler, "Three Cases of Dyspepsia." Incidental business: Action on the proposed Amendment to By-Law XV by the addition of the following clause: "The nominating committee is requested to report annually the names of one-fifth of the candidates for members of the Council from Fellows who have not held the office of Councillor during the three preceding years." Reports of the Treasurer, Librarian, and the Committee on Social Meetings. Election of officers. Supper after the meeting.

**HERBERT L. BURRELL, M.D., Secretary**

**ASSOCIATION OF GENITO-URINARY SURGEONS.**—The first annual meeting of this Association will be held at the Laurel House, Lakewood, N. J., May 17 and 18, 1887.

**R. W. TAYLOR, M.D., New York, Temporary Secretary.**

#### ERRATUM.

The name of the author of the article on "The Circulation of the Blood in the Orbit. Studied by means of the Plethysmograph," page 269 of the last issue of the JOURNAL, should have read F. W., and not W. F. Ellis.

#### APPOINTMENT.

Dr. J. Orne Green has been appointed Aural Surgeon to the Massachusetts General Hospital.

#### OBITUARY. JOHN SYDENHAM FLINT, M.D.

Dr. John S. Flint, of Roxbury, Mass., died on Saturday, April 16th, at the age of sixty-three, from double pneumonia, after an illness of four or five days. He was born in Leicester, Mass., and graduated from Harvard College in 1843, and from the Harvard Medical School in 1846. He was of a medical family, his father having been a physician; he was also related to the late Dr. Austin Flint, of New York. The greater part of his professional career was passed in Roxbury, where he enjoyed an excellent practice.

## DEATHS FROM GONORRHEA.

BY ANNE POST, M.D.

In looking over the literature of gonorrhoea I have been particularly impressed by the many fatal cases recorded, and the variety of ways in which the fatal termination may be brought about. Every surgeon realizes the immense death-rate from strictures which owe their origin to a gonorrhoea of many years previous, but the fact that death occurs from the acute disease is seldom realized and may even be novel to many. I have taken pains to bring together a series of cases to illustrate the possibility of such an accident and the various means by which it occurs. To judge the disease from such a collection as is here presented would be entirely unfair, but it is not unfair to represent the disease in its most serious aspect as an offset to the trivial way in which it is so often regarded.

Some of the following cases illustrate improprieties in the conduct of the disease, but they serve my purpose well, for some at least, of the severest cases owe their severity to improper conduct on the part of either physician or patient. It cannot be far from the truth, to say that a very large proportion of the severe complications of the disease are directly brought about by some impropriety.

As confined to the anterior urethra, that is, the urethra anterior to the compressor urethrae muscle, the disease is ordinarily harmless, so far as immediate danger goes; yet even here fatalities occur. Voillemier<sup>1</sup> reports a case:

A man with a urethritis and a very painful chordee "broke" the chordee in true French fashion and died of purulent infection. At four and one-half centimetres from the meatus was a complete rupture of the canal, and the cavernous bodies were almost completely destroyed by suppuration.

Another case occurred in the practice of Villeneuve.<sup>2</sup> The patient was suffering from "intense chordee and continual erection, to relieve which twenty leeches were applied. Two days after a scab formed on the most prominent part of the curve; when it fell off the corpora cavernosa were exposed for a length of three or four centimetres. Rigors, pains in the joints of the upper extremities, purulent effusion into the left elbow joint and delirium followed, with arterial hemorrhage from the slough on the penis, which caused the patient's death. Phlebitis of the prostatic plexus, metastatic abscesses in the left lung and liver, and pus in the elbow-joint were found after death." Pyæmia is one of the most frequent of the fatal terminations, and follows prolonged suppuration due primarily to gonorrhoea in other portions of the genito-urinary tract, as we shall have abundant opportunity to see later.

When the disease extends beyond the mid-urethral sphincter, as it so often does, it opens up a field of greater danger. In the prostatic gonorrhoeal inflammation may be follicular when it is one of the causes of obstinate gleet; or parenchymatous abscesses may form, which may open externally, into the rectum, or the urethra, or in any two of these three

directions. When the pus is discharged through the urethra the symptoms usually vanish with great rapidity. Not unfrequently, however, according to Fournier, the suppuration from a prostatic cavity continues indefinitely and proves fatal after a long period of suffering and cachexia. Dr. Pitman, of St. George's Hospital, reports a case in which the death was rapid.

John E., aged twenty-five, a baker, was admitted April 25th to St. George's Hospital. He had had gonorrhoea for a fortnight, with pain across the loins. Four days before admission the pain increased in severity, and extended down the legs so that he had to discontinue work. He never had any chills. On admission he had much the aspect of a fever patient. He was unable to pass urine except with the aid of a catheter. May 1st, he was delirious with involuntary evacuations. Eight days after admission he died.

*Post-mortem.* The body was in good condition; there was profuse purulent discharge from the urethra which had collected about the glans penis. The right kidney was healthy, in the left the pelvis and ureter were rather more vascular than usual. Peritoneum healthy. The mucous membrane of the urethra seemed slightly injected in parts, but this appearance was so slight that little reliance could be placed upon it. The muscular fibres of the bladder seemed rather thicker than natural, but showed no trace of inflammation. Between the bladder and the rectum was a large abscess which at the time of the examination communicated with the floor of the prostatic urethra by two ragged orifices. The tissue of the prostate gland was extensively destroyed and eroded by the abscess, and on squeezing the abscess, pus could be made to exude by the prostatic ducts; but in parts near the abscess the tissue of the prostate seemed healthy. The cellular tissue in the neighborhood of the abscess was condensed; in other parts of the pelvis it was healthy.

The account allows us to wonder whether the abscess might not have been due to punctures from the catheter. Be that as it may, the dependence of death upon the gonorrhoea would be undisputed.

In these cases the suppuration itself seems to have been directly the cause of the fatality. It is more often the cause which sets in action some secondary cause. In the *Annales des Maladies des Organes Génito-Urinaires*, (Volume II, No. 9,) is a case in which the abscess of the prostate was followed by pyæmia. A man had had four years previous his first gonorrhoea which lasted six or seven weeks. Two months previous to the date of narration he contracted a second which was nearly well when retention of urine appeared. Catheterism was performed with the effect of causing marked bleeding which continued at intervals for three or four days, until his entrance to the Hospital Necker, under the care of Guyon, where he died shortly, with partial suppression, albuminuria, and uræmia. Autopsy showed the prostate to be the seat of a parenchymatous abscess, which was the cause of the retention, and the posterior urethra was torn by the point of the catheter. The bladder showed in the vicinity of the neck and the trigone very marked inflammatory alterations, the right ureter was dilated and corresponding kidney was intensely congested. There were metastatic abscesses in the lungs, the liver and other organs.

Lallemand gives a case of a man who had frequent

<sup>1</sup> Voillemier, p. 9, Case 8.  
<sup>2</sup> Gazette Hebdom., 1873, p. 213. Quoted in Milton on Gonorrhoea, p. 215.

attacks of gonorrhœa, and died with an abscess of the prostate, and pyelo-nephritis.

Occasionally, gonorrhœal cystitis is succeeded by pyelitis, the inflammation creeping up one or both of the ureters to involve the kidneys. This process is recognized more frequently since infection from external sources has come to play so great a rôle in surgical pathology.

Dr. Murchison reports the following cases: Stephen H., aged twenty-eight, a grocer's assistant, was admitted to the London Fever Hospital on June 4, 1885, in a state of profound coma, with low muttering delirium and dry brown tongue. Three hours after admission he died, having had several attacks of general convulsions. The symptoms obtained were of little value. After his death it was ascertained that he had been suffering for some time from gonorrhœa, for which he had been taking copaiba, and that the cerebral symptoms had come on suddenly only thirty hours before admission. In fact, he had gone to his employment on the morning of the day before admission into hospital.

After death the entire length of the urinary passage from the anterior end of the urethra to the pelves of the kidneys, was found to be in a state of intense inflammation, the mucus membrane being tightly injected and its surface bathed with pus. Both ureters were full of thick, yellow pus. The kidneys were much enlarged, but their outer surface was quite smooth; they were of a deep purple almost black hue and a quantity of dark blood dripped from their cut surface.

Marie D., lady's maid in a nobleman's family, was admitted into the London Fever Hospital on January 31, 1866, quite unconscious; her breathing became stertorous, the stupor more profound, and she died February 2d.

After death it was ascertained that she had appeared well during the day before admission, having travelled on that day from Paris with the cook, who served in the same family. On reaching London in the evening she ate a good meal, but during the night she wandered a good deal, and on the morning of January 31st, she had a convulsive fit followed by unconsciousness.

At the post-mortem the membranes and substance of the brain were found to be intensely hyperæmic, but there was no exudation of lymph and no sign of tubercle within the cranium or lungs.

Both kidneys were in the early stages of acute nephritis, large, smooth and almost black from intense congestion. The ureters and the pelves of the kidneys were full of thick yellow pus, the bladder also contained pus. The lining membrane of the vagina, the urethra, bladder, ureters and pelves was intensely red.<sup>3</sup>

DeLafield has seen one similar case. The patient was a prostitute who came into the hospital with specific (that is, gonorrhœal) vaginitis. After a few days she developed symptoms of an acute cystitis; after a few more days she was attacked with rigors and a febrile movement, passed rapidly into the typhoid condition and died. At the autopsy there were found acute cystitis, pyelitis, and numerous small abscesses in both kidneys.

At the discussion on Dr. Murchison's cases, Dr. Greenhow mentioned a similar case which he saw when he was a student at Edinburgh. A man died in

a state of coma of thirty-six hours' duration. He was supposed to have been poisoned, but was the subject of gonorrhœa, for which he had been taking copaiba, and using injections. Sir William Newbiggin attributed the death to cerebral metastasis from gonorrhœa checked by treatment.

In the summer of 1885 I was asked to examine for stone, the bladder of a young boy suffering from cystitis; he denied gonorrhœal antecedents and his history as given warranted a suspicion of calculus. The examination was made. It was followed by an exacerbation of symptoms, and a pyelitis became evident.

After some months of suffering the boy died, evidently of pyelitis, though no autopsy was obtained. During his sickness a more rigid cross-examination elicited the fact that the cystitis was gonorrhœal. Of course the examination ought not to have been made, the history of gonorrhœa ought to have been learned at first. I am not sure that the disease had not already extended up the ureters when the examination was made, but the increase in severity of symptoms followed very closely on the examination, and the case may well stand as an illustration of the impropriety of meddling recklessly with an inflamed bladder. The ease with which such an error may occur, was illustrated within a very few days. A little boy of thirteen was referred to me at the City Hospital for examination for stone, by a gentleman whose diagnostic ability in urinary cases is well recognized. The boy complained of pain at the end of micturition and the occasional passage of blood in small amounts. He was undersized and looked much less than his years. The house-surgeons recognized him as a recent victim of gonorrhœa, and a more careful review of the case established the diagnosis of gonorrhœal cystitis.

Peritonitis and subperitoneal phlegmon ought to be joined to the number of the possible complications of gonorrhœa.<sup>4</sup> These accidents are the remote effects of gonorrhœal inflammation propagated from the urethra to the peritoneum or to the subperitoneal cellular tissue through the intervention of the deferent canal, the vesiculae seminales, the prostate, perhaps from the bladder, the ureters, or the kidneys and from the cellular atmosphere which surrounds them, so that gonorrhœal peritonitis may begin at various points in the pelvic region, at the recto-vesical cul-de-sac, at other times from the internal orifice of the inguinal canal and will always be preceded by more ordinary complications. Peritonitis after inflammation of the cord was observed by Hunter, and Ricord is said by Fournier<sup>5</sup> to have observed it many times. Ricord is also reported by the same authority to have seen two cases in which gonorrhœal inflammation of the prostate was propagated to the peritoneum, causing at first a pelvic peritonitis which became general and terminated fatally.<sup>6</sup>

The following case is interesting as bearing upon the subject under consideration and also from the distinguished names attached to it.

L. L., aged sixteen, entered the Hospital la Charité June 4, 1856, in the service of M. Velpeau, for a left blennorrhagic epididymitis. The gonorrhœa had lasted fifteen days and the epididymitis five days. The epididymitis proceeded rapidly towards resolution and the discharge had ceased when the patient was taken

<sup>6</sup> Non. Dict. V. p. 203.

<sup>3</sup> Clin. Soc. Trans. Vol. IX, 1876.

with chills and general malaise and vomiting. On the 17th the patient was transferred to the medical service of M. Cruveilhier, and on the 21st he died of peritonitis. The autopsy showed a generalized peritonitis. Pus exuded from the prostate. The left vesicula seminalis contained a small quantity of purulent liquid. That vesicula was larger than the right, and the cellular tissue which surrounded it was very injected and thickened. The deferent canal was greatly injected as well as the surrounding cellular tissue, and it adhered closely to the peritoneum which covered it. The peritonitis had started from the recto-vesical cul-de-sac.

It does not seem very hazardous to say that some, at least, of the cases of peritonitis in the male, of unknown or supposed idiopathic origin may have arisen from gonorrhoea, in one of the many ways mentioned.

Gonorrheal rheumatism opens up a long list of serious cases, though fatal cases are uncommon. But a short time ago the comparative table of the symptoms of gonorrheal and ordinary acute rheumatism, which is almost inseparable from an account of gonorrheal rheumatism, used to specify that gonorrheal rheumatism did not attack the heart. That is no longer considered a characteristic of the gonorrheal disease. In 1854, Brandes, of Copenhagen, reported a case of endocarditis, and at least sixteen cases had been reported up to 1883, the date of Mr. Milton's book, in which the cases are collated. Of these, two were fatal. One is given by M. Tixier from the practice of M. Lorain. "There was cardiac complication with bellows sound; also disturbance of circulation, succeeded by signs of mitral insufficiency, with considerable hypertrophy, all following upon blennorrhagia with rheumatic pain. Later on came asystole succeeded by death from cardiac disease."

In 1833, Mr. Stanley published the paper on "Irritation of the Spinal Cord and its Nerves, in Connection with Disease of the Kidneys," on which was founded the theory of a reflex urinary paralysis. In that paper were narrated two cases in which complete motor paralysis involving the lower extremities and the sphincter, together with loss of sensation, ensued upon gonorrhoea; one was fatal in sixteen hours, the other in about a fortnight with sloughing.

Many other instances of supposed reflex paraplegia following upon gonorrhoea, some of which have ended fatally and some in recovery, are scattered through medical literature. Sir W. Gull has shown that these cases of supposed reflex paralysis from gonorrhoea really depend upon distinct inflammatory changes in the cord, appreciable with the microscope, and that these changes are produced by means of an infection whether purulent or specific. Two of Gull's cases are as follows.<sup>2</sup>

The patient contracted gonorrhoea eight months previous. On January 18, 1855, he thinks he slept in a damp bed and three days afterwards began to have pain and weakness in the legs, and about the neck and occiput. On the 26th, he had a rigor and the weakness of the legs was rather suddenly increased with loss of sensation about the ankles and formation. Incontinence of urine came on at the same time with bed-sores, frequent involuntary spasms of both legs, etc. He died rather suddenly May 16th, four months from the beginning of his symptoms. To the

naked eye the cord showed no changes, but extensive disorganization was evident, was shown by the microscope.

Henry F., aged twenty-one, had gonorrhoea many times and a permanent gleet. He was quite well on Tuesday morning, March 1, 1833. In the afternoon he began to have pain between the shoulders, and diarrhoea. Pain in the back increased during the night and spasmodic tremblings in the legs. On March 4th, at Guy's Hospital under Mr. Bransby Cooper, the following condition was found: complete loss of motion below the sixth dorsal vertebra; the muscles of the seventh intercostal space did not act in respiration; sensation was perfect above the line indicated, but on the abdomen pricking the skin gave no pain and only the faintest sensation; in the legs there was complete anaesthesia. A fortnight later he died, exhausted by irritative fever and sloughing. The cord was generally softened as high as the middle of the dorsal region. Between the bladder and rectum there was an irregular abscess, with sloughing walls, communicating with the bladder by a large perforation of its coats. Near the bulb was a more recent abscess filled with healthy pus.

If these two cases of Gull's stood alone, the association between gonorrhoea, and the changes in the cord and death might be regarded as accidental, but they belong to a series of cases sufficiently long to be quite convincing.

We have seen pyæmia as a frequent cause of death in various complications. Sometimes, however, purulent infection takes place without other appreciable lesion than the gonorrhoea itself. Mr. Milton makes an especial heading of gonorrheal pyæmia under which he relates two cases, one from Dr. Charteris,<sup>3</sup> a boy of seventeen with his third case of gonorrhoea with retention of urine for which no cause is given. He died with the usual symptoms of pyæmia and with purulent collections in both shoulder-joints. The second was a man of thirty whose gonorrhoea had already lasted two years.

No attempt has been made to include every published case of fatal gonorrhoea in this list. These are rather some of the cases that have fallen under my notice, and which have been selected to represent the many ways in which the disease may prove fatal. The list might have been very materially — I am tempted to say indefinitely — increased. The results of stricture have been purposely omitted, as well as those numerous cases peculiar to women, in which pelvic inflammation consequent on gonorrhoea wears out the patient with months of suffering.

In these cases the ages are rarely given, but the number of times in which the victim is said to have been a boy under twenty is noticeable. I am inclined to believe that the disease is often exceedingly severe in the precocious youths who acquire it while yet in their early teens. Some of these boys are rather wanting in physical development, and some, at least, would be described as scrofulous — a class exceedingly prone to a severe type of urethral inflammation.

Extended travelling, as in the case of the lady's maid of Murchison's case of pyelitis, is to be feared during the acute disease. It hardly seems possible that the rapid death of that young woman could be attributed solely to her journey from Paris to London; but serious difficulties, short of death, occur often enough

<sup>1</sup> Milton on Gonorrhoea, p. 316.

<sup>2</sup> Medico-Chirurg. Trans. t. xxxix, p. 200. 1856.

<sup>3</sup> Brit. Med. Journal, 1876. Vol. ii, p. 712.

under similar circumstances to make a journey of any length particularly undesirable. Some of the more active occupations entail similar unpleasant consequences.

Finally, these cases serve to emphasize the fact that gonorrhea may be an exceedingly grave disease, which does not exhaust itself in the urethra, and that its possibilities render it an object worthy of study by the conscientious student, and of honest care by the attending physician.

#### A CASE OF HODGKINS' DISEASE.<sup>1</sup>

BY HAROLD WILLIAMS, M.D.

I was called, July 10, 1886, to see Mr. D., a young gentleman, twenty-seven years of age, a chemist by profession, and married. He had been ill since May, 1886, and had come to Nantucket in June, 1886, with the hope that a change of climate might prove beneficial. The history of his illness was nearly as follows: In May, 1885, while out walking, Mr. D. suddenly felt dizzy, and his vision became defective. He walked home with difficulty, his difficulty in locomotion being due, he thought, to an inability to hold himself erect. Previous to this he had been perfectly well. There was no history of malaria nor syphilis. A few days later Mr. D. became totally deaf, and, at this time, a swelling made its appearance over the inner malleolus of the left leg. This swelling increased in size; was intensely painful, and was of a bluish color, but subsided at the expiration of ten days. There was no injury. As the swelling at the ankle began to subside, several smaller swellings appeared in both legs and thighs. These smaller tumors also disappeared, and were, in their turn, followed by a swelling as large as an orange in the right buttock. At this time there was paralysis of the left leg and thigh. This swelling in the buttock slowly diminished in size for three weeks, when it again increased, and again diminished. His physician told him that his spleen was enormously enlarged; and one oculist who was consulted said that his impaired vision was due to hemorrhage, while a second oculist assured him that there had been no hemorrhage. This takes us up to Christmas, 1885, on which day the patient went out-doors. After this there was gradual improvement, though it is probable that the swelling in the buttock never totally disappeared, and the deafness still persisted, though slightly improved.

On July 10th, when I first saw the patient, he was in bed. He complained of much pain, and was so deaf that I could scarcely make him understand me. His body was well nourished; the lips were red, the fingernails pink, and there was no appearance of leucæmia. Pulse 89, temperature 102°. There were three tumors: one on the left side of the thorax, bounded by the sternum, the third rib, the posterior axillary line, and the eighth rib. This was the largest, and I considered it the forward extension of enlarged axillary glands. The second was in the neck, extending downward beneath the left clavicle, and upward to a point two inches above it. I could not estimate its lower boundary, because of the pain caused by percussion. The third tumor was in the right buttock, and seemed to lie above the gluteus maximus. It was as large as

a very large orange. These tumors were very hard to the touch, and the skin over them was of a reddish-blue color, hot and painful, but movable. There was enlargement of the spleen, huskiness of speech, slight difficulty in swallowing, and defective vision. The patient was taking iodide of potassium and small doses of morphia, to relieve pain. This treatment I continued.

On the following day the patient was much worse, and in the afternoon I found him in a semi-comatose condition, from which it was difficult to rouse him. He had vomited at different intervals throughout the day, and there was much difficulty in swallowing and articulation. Pulse 150, and very feeble; respirations 40. The condition of the tumors seemed, outwardly, the same.

The vomiting, feeble and rapid pulse and respiration, and the disturbance of the functions of the larynx, seemed to me to denote pressure by the tumor in the neck on the deep-lying nerves of the trachea, and I warned the family that I considered the case nearly hopeless. Brandy and coffee were given by the rectum.

Instead of dying, as I expected, the patient rallied, and for three days there was slight amelioration of the symptoms, though the tumors seemed outwardly the same. At this time I prescribed Fowler's solution in ℞. doses, three times a day, to be increased up to ℞.ss. After this there was constant improvement, although, as the glands subsided, a condition of extreme leucæmia, with furuncles and a carbuncle, supervened. The patient was of a waxen hue, his lips were colorless, and the nails white. To the naked eye, the blood seemed barely tinged with red, and, under the microscope, showed a marked change in the proportion between the red and white corpuscles. As no proper apparatus was at hand, I could merely estimate by what Osler calls "the rough and ready method," that the white corpuscles seemed nearly as numerous as the red.

In October the patient considered himself perfectly well, and there were no symptoms or signs of his illness, with the exception of the deafness, which, though much diminished, was still a cause of serious annoyance.

This case I consider to have been one of Hodgkins' disease, or pseudo-leucæmia lymphatica, followed by leucæmia.<sup>2</sup> The diagnosis would seem to lie between lymphatic leucæmia and pseudo-lymphatic leucæmia, and is based upon the pathological condition of the blood, and upon clinical differences. In lymphatic leucæmia there is an increase of the white corpuscles, and in pseudo-lymphatic leucæmia there is little or no such increase. In the present case no such analysis was made, but nothing in the aspect of the patient suggested such an increase until the swelling of the glands began to subside. But, on the other hand, the absence of the external appearances of leucæmia; the absence of hemorrhages and diarrhoea; and the enormous swelling of the glands, would seem to indicate Hodgkins' disease. In either case the prognosis is unfavorable, and doubly so in a case of such long duration as the present.

I have ventured to report this case, in spite of the imperfection of my notes, because it seems to me to demonstrate the decided advantage following the administration of large doses of arsenic, prescribed as it was in this instance, to a patient who had been ill for a period extending over fourteen months. The idea

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology, and Hygiene of the Suffolk District Medical Society, March 9, 1887.

<sup>2</sup> Vide case of Fleischer and Ponzoldt, quoted by Osler in *Pepper's Syst. Med.*, Vol. III, p. 682.

was suggested to me by an article by Karnvski,<sup>3</sup> who, in 1884, reported three recoveries under this treatment. The arsenic was given in gradually-increasing doses, until the dose of  $\text{mxx}$  t.i.d. was reached, in which quantity it was continued until there was puffing of the eyelids and nausea. Then it was replaced by quinia and iron for a week, when it was again resumed in the same manner.

This treatment has been continued in gradually-decreasing doses up to the present time, the patient now taking  $\text{miii}$  of the Fowler's solution, t.i.d., every other week. I have not seen him since October, 1886, but in a letter I received from him last week, he reports: "I am perfectly well, with the exception of my deafness, and weigh 170 pounds — not a bad weight for a man of my size."

### Clinical Memoranda.

#### A CASE OF ALEXANDER'S OPERATION.<sup>1</sup>

BY JOHN B. SWIFT, M.D., OF BOSTON.

Mrs. B. came under my care at the Carney Hospital, March 18, 1886, with the following history: She was thirty-seven years old, born in Canada, and had had one child. The labor was a severe one, and she had been torn. Since then she had suffered from "falling of the womb," the organ coming outside. By various means she had kept it up, so that she could work, until the friction caused by the bandages had rendered the parts sore, and she would be obliged to stop work until the abrasions had healed. Lately, she had been wearing a cup-shaped pessary, but with no better success.

An examination showed rupture of the perineum to the sphincter ani, bilateral laceration of the cervix, a small recto-vaginal fistula, and complete procidentia of the uterus. The cervix was hypertrophied, excoriated, and there was a deep ulceration of the tissues, caused by the rim of the pessary which she had been wearing.

The uterus was replaced and held in position by cotton tampons, wet with glycerine and tannin, and the patient kept in bed until the excoriated mucous membrane had healed. Attempts were then made to keep the uterus in place by various pessaries, but without success, and finally, it was decided to perform the Alexander operation of shortening the round ligaments. The operation was explained to the patient, and she readily consented. Owing to the extensive laceration of the cervix, and the hypertrophy of the uterus, it measuring almost four inches, it was thought best to first repair the cervix, hoping, by this means, to reduce the hyperplasia, and thus lessen the weight, so as to give a better chance for success in the succeeding operation. This was done April 17th, and resulted successfully.

Three weeks later, with the assistance and advice of Dr. F. B. Harrington, the Alexander operation was performed.

I will not enter into the details of the operation, as they probably are familiar to you all, but will only say that the ligaments were easily found, and shortened about two inches. By drawing on the ligaments, the uterus readily ascended in the pelvis, and was held in position by Dr. Harrington while the ligaments were being secured. They were not cut, but were folded and tucked into the wound, being fastened by silk sutures passed through the pillars of the ring and the tissues at the bottom of the wound. The incisions through the skin were closed by catgut sutures, and the wounds dusted with iodoform and dressed with sublimate gauze.

As there was no perineum, it was feared that a pessary would not stay in place, so the vagina was packed with cotton pledgets, and a T-bandage adjusted. The catamenia, which had never been regular, came on the second day after the operation, and the packing had to be removed, a pessary being substituted, which proved, in the end, to work successfully.

For three days the patient was nauseated continuously, and vomited everything taken by the mouth. She was nourished by enemata. Hyperdermic injections of morphia and atropia over the stomach were given for the nausea, but whether or not they did any good, I cannot say. At any rate, on the fourth day she could retain food, and from that time on had no further trouble.

The temperature was never above the normal, and, aside from the vomiting, the convalescence was uninterrupted. She was kept in bed for three weeks, and then allowed to sit up, but she did not walk any for another week. At the end of that time the pessary was removed, and she was allowed to go about and do light work. On my visit, the next day, I was told that the uterus had again descended; but an examination showed that what was considered the uterus, was the anterior vaginal wall, which was prolapsed. The uterus was in good position, and held firmly in place.

It was decided not to repair the perineum at that time, but to wait and see if the uterus would remain in place without this additional support. This was explained to the patient, and she was told to return at once, should there be any indication of the old trouble. She came to the hospital last September, about four months after the operation, saying that she was all right, and had been doing house-work. An examination showed the uterus just as it was on her discharge from the hospital, well up in the pelvis, slightly anteverted. The prolapse of the anterior wall, of course, was the same, but she declined the perineal operation, saying that she was well enough as she was.

— Hartmann describes in the *Berliner Klin. Wochenschrift*, 1886, p. 612, the results of some experiments in the self-induction of edema and albuminuria, by the exclusive use of certain forms of nourishment for a given time; for instance, he ate chestnuts, lentils, peas, cheese, etc., each for a series of days, and with no other ingestum but water. He twice produced general edema, once with and once without albuminuria; the former, under an exclusive diet of sausages, the latter with bread only, (1,000 grams in twenty-four hours). The uncomfortable symptoms which the enthusiastic experimenter induced all passed away with a return to ordinary methods of living.

# A CASE OF PERINEPHRITIC ABSCESS FOLLOWING TYPHOID FEVER; OPERATION; RECOVERY.

BY WILLIAM H. DEVINE, M.D.

E. F., a boy, six years of age, was the second case of typhoid fever in the same family, and was first seen by me November 9, 1886. There was nothing remarkable in the course of the fever, and convalescence began in three weeks. His mother permitted him to sit up before, and contrary to my orders, but said that he was feeling so well, she was unable to restrain him.

December 16th. I was called again to see my patient. His mother said that since my last visit, about two weeks previous, Eddie had been around the house, and seemed apparently as well as usual for about a week; then she noticed that he seemed languid and disinclined to exert himself. Later, she noticed a peculiar kind of lameness in the left leg, and that he kept it flexed when lying down, and that an attempt to straighten it, on her part, caused him great pain. She also thought that he was feverish at night, and said his urine was very scanty. On examination, I found extreme flexion, and any attempt to straighten it caused excessive pain. I also found marked tenderness and flatness in the left lumbar region. The urine was much diminished, only four ounces in twenty-four hours, but an examination of it revealed nothing especially abnormal.

On December 19th, I found the tenderness in the left lumbar region increased, and noticed some fullness. I decided to aspirate, and, doing so, I obtained about four ounces of thick, creamy pus. Having established the diagnosis, I determined to make a free opening, which I did on December 21st, with the assistance of Dr. E. O. Otis and Dr. F. Stuart. I made an incision about three inches long in the lumbar region, parallel with the vertebral column, and about two inches to one side of it, between the last rib and the superior crest of the ilium. After careful dissection I came upon the abscess-sac, and, on incising which, I evacuated about twelve or more ounces of pus. The cavity was thoroughly washed out with a solution of 1-60 carbolic acid, two drainage-tubes were inserted, one extending to upper, and the other to lower limit, and an antiseptic dressing of bichloride gauze applied, which was prepared, in the house, by soaking cheese-cloth in a solution of corrosive sublimate, of about one to two thousand strength, and drying it. On the day of the operation, the temperature was 103.5°. The next day it dropped to 101° in the afternoon, and 100° on the third day. After this it was normal, and continued so. The discharge of pus was profuse for the first week, and after that, gradually diminished. The cavity was washed out every day with an antiseptic solution, and an antiseptic dressing applied.

In two weeks from the date of the operation, the upper drainage-tube was removed, and about a week later, the lower one, when the wound quickly healed. Thus the boy was practically well in three weeks from the date of the operation. There was no evidence at any time of any renal trouble, in this case, to account for the abscess. The exciting cause, so far as one can fix upon any, might have been exposure during convalescence, for it is known that the boy was removed from the room in which he had been sick to one of a much lower temperature. It is known, also, that a sudden chill is an exciting cause, and further, that

perinephritis occurs during the course of, or as a sequel to, the continued and exanthematous fevers.<sup>1</sup>

This case well illustrates what can be accomplished by a timely and free exit of pus and proper antiseptic precautions, under very adverse circumstances, for the patient was in an extremely debilitated condition from his previous illness, and his surroundings were poor and unhygienic. Indeed, after I had determined on the condition and treatment required, I recommended the removal of the boy to the hospital, that he might have a more promising environment; but his parents refused, saying that he would die any way, and they preferred to have him die at home.

"When suppuration occurs," says Mr. Morris, "the prognosis depends chiefly upon two things: the early and free evacuation of the pus, and the cause of the disease. Incisions not only save life, but also hasten recovery, and in uncomplicated cases the recovery is complete." To the truth of this, the above case can testify.

## Reports of Societies.

### MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT. SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

MARCH 9, 1887. The meeting was opened at 8 o'clock, by Dr. F. I. KNIGHT, Chairman. On motion, the reading of the records of the last meeting was omitted.

#### PHYSICAL CULTURE.

A communication, in the form of a resolution from the Norfolk District Medical Society, upon the importance of the physical training of the young, was read by the Secretary, who called attention to the fact that this Society also had appointed a committee to act in concert with similar committees appointed by the sister medical societies, but that the committee from this District had as yet made no report, and it was not known whether anything had been attempted in the way of progress by the members of this Society.

Dr. HENRY I. BOWDITCH said that he considered this subject to be of the greatest importance, and one which should claim the earnest attention of all who are interested in the welfare of the rising generation. He had long been convinced that the State is not doing its duty toward the youth of both sexes in requiring an increasing amount of intellectual labor in the schools, without providing for the development of the physical constitution of the pupils. He moved the appointment of a committee of three, who should take the matter into consideration, and report at the next meeting. The Chairman stated that a committee had been appointed at a former meeting of the Section, and that it might be advisable to urge that committee to prepare a report, rather than to appoint a new committee. Dr. Bowditch then withdrew his motion.

Dr. KNIGHT said that, in his opinion, the Suffolk District Medical Society is the body which should take action upon the matter.

#### MILK SUPPLY.

The Secretary read a communication from one of

<sup>1</sup> Henry Morris. "Surgical Diseases of Kidney," p. 207.

the members of the Section, who was not able to be present, stating that the milk now supplied to the citizens of Boston is received by the consumer at a time when it is from forty-eight to seventy-two hours old, and presenting a resolution that, after the first of September next, the physicians of Boston should use every endeavor to secure the delivery of milk directly to the consumer on arrival of the milk at the milk depots in the city, instead of allowing it to be taken to the stables of the milkmen, as is now done, where it is exposed to deleterious influences, as well as to the dangers of adulteration.

Dr. E. W. CUSHING thought that no action which could be taken by this Society would have the desired effect, as the whole matter is outside of the control or the influence of the physicians. A committee was, on one occasion, appointed from this Society, but no tangible results had accrued from the labors of that committee. He has little faith in the efforts of any committee from this Society in accomplishing the desired reform in the distribution of the milk-supply of this city.

Dr. B. F. DAVENPORT said that the facts contained in the resolution just presented are true. It is in the limits of his personal knowledge that the milk of our city is often unnecessarily detained in the stables of the milkmen, and is more or less adulterated and diluted before it is at length delivered to the consumer. There is no reason why the requirements of the resolution should not be easily met by the dealers, and he is of the opinion that many of the milkmen would gladly dispense with the extra handling of the milk, and thus prevent a certain amount of change in its character.

On motion of Dr. E. W. CUSHING, the resolution was laid on the table until the next meeting of the Section in order to afford an opportunity for the mover of the resolution to be present and more fully explain the matter.

The Secretary read a letter recently received by him from the Secretary of the Chicago Medical Society, asking for the list of officers of this Society, and for a copy of its By-laws. On motion, it was voted that the letter be transmitted to the Secretary of the Suffolk District Medical Society, for the consideration of the parent society.

The Secretary stated that he had been requested by the Secretary of the Suffolk District Society to call the attention of the members of the Section to the Articles contained in the By-laws of the General Society in relation to the distribution of the lists of nominations for the offices of the Society, and stated that, in accordance with the requirements of the By-laws, the report of the nominating committee would be distributed at this meeting. This was done, with the aid of Dr. F. C. Shattuck. The regular business of the meeting was then taken up.

The first paper of the evening was entitled .

**A CASE OF CHRONIC ARSENICAL POISONING OF SUPPOSED CRIMINAL NATURE, WITH ESPECIAL REFERENCE TO THE MEDICO-LEGAL ASPECT,**

by **DRS. E. W. CUSHING AND MORTON PRINCE.**

Dr. Cushing stated that the circumstances of the patient made the case specially interesting, from the evident motive which could be traced. The patient was a young man, supposed to be in possession of property to the extent of about four million dollars, and

was alone in Boston. He was found at the house of a friend of his, not of his family, on Beacon Street, and this "friend," with the assistance of his wife, took the sole direction of the nursing of the sick man. The medical treatment was in the hands of a so-called physician, really an apothecary and chemist. A large amount of the patient's money had been invested in the manufacture of a patent medicine, in which the "friend" at whose house the patient was staying was also interested.

Dr. Cushing remarked that it might be useful to members of the medical profession to know how difficult it is to bring a case before the courts, even when the evidence is apparently plain and convincing.

PROF. E. S. WOOD stated that he was in a position to add somewhat to the report of the case, in the presentation of some of the results of the quantitative analysis of the vomitus and the excretions from this patient. The quantitative analysis was made, in this case, only for the personal satisfaction of Professor Wood, as the case had not advanced sufficiently far in the way of a prosecution to call for the analysis in behalf of the courts. A complete analysis is not usually made at so early a stage in the investigation of similar cases.

The vomitus, which was placed in his hands on May 1st, contained one-fourth of a grain of arsenic. That of May 8th contained one-third of a grain. The urine of May 1st and 2d contained 5.4 mg. It was thought that this amount of arsenic might have been contained, as an impurity, in the medicines prescribed by the person attending the patient. These were examined, and were found to be free from arsenic. The intermediate urine, until June 1st, was not examined, but that passed on June 1st was examined, and was found to be free from arsenic. The date when the arsenic disappeared from the urine is, therefore, not yet definitely known. The only other case in which analysis was carried out in this way was that of a patient who, by mistake, took, during a considerable period, a poisonous dose of Fowler's solution, and the symptoms of arsenical poisoning were rapidly induced. In this case, analysis at the end of six and one-half weeks showed arsenic, but the urine, when examined at the end of seven and one-half weeks, did not contain arsenic. The occurrence of paralysis is not confined to chronic forms of arsenical poisoning, but may follow acute poisoning from this cause. Seligmüller quotes several such cases.

DR. PRINCE said that he had made, by request, an examination of the nerves and muscles in this case. At that time the patient was almost completely paralyzed from head to foot, only a few movements being left, and these difficult and painful. Even moving the limbs passively caused great pain.

There was more or less complete loss of sense of touch over all four extremities. Sense of pain was increased over some parts, but perception of it was retarded three seconds by the watch. Perception of Faradic current also diminished.

Loss of Faradic excitability of all muscles of legs, forearms and hands. Triceps of right arm responds feebly, but biceps of both well. Faradic excitability of ulna and median nerves of both sides lost, also of nerves of legs.

To the galvanic current there was a most exquisitely developed reaction of degeneration in all the

muscles of the right forearm and hand (including loss of reaction in the nerves).

The same was found true of the extensors of the left forearm. The examination was not continued further on account of pain caused the patient by movement of the limbs. The same condition of affairs probably existed in all the paralyzed muscles.

The interest in this case, as indicated by the title of the paper, centered in the question of the nature of the paralysis, and the other allied symptoms. Were they due to arsenic or to alcohol? In the first place there is no question but that arsenic was given to the man, and that, too, in poisonous doses. But on the other hand, the man was a hard drinker, was in the habit of going on constant sprees, lasting many days at a time, and had just been on a hard spree, when the attempt was made on his life. Now the *paralytic* picture presented was just that of alcoholic paralysis in its most severe form. Alcoholic paralysis has only recently been thoroughly studied and understood; in fact, the best observations have been made during the last two years, and since the above case occurred. The *clinical* picture is just such a one, in almost every detail, as that which we are discussing. There is the extreme and general paralysis, the loss of sensation with hyperaesthesia, the pain and the atrophy with the reactions of degeneration. The resemblance can even be extended to the mental condition. According to Dreschfeldt<sup>2</sup> and Buzzard<sup>3</sup> there is a peculiar and characteristic delirium observed in alcoholic paralysis. A similar mental condition was present in their case.

On the other hand, the clinical picture is also like that observed in many of the cases reported of arsenical poisoning. In the severe cases there seems to have always been present the main and salient symptoms, namely, paralysis with atrophy and reaction of degeneration, loss of sensation, pain, and hyperaesthesia.

Clinically and aetiological, then, it must have been difficult especially, as a medico-legal question, to eliminate either the arsenic or the alcohol as a factor in causing the paralysis and allied symptoms.

*Pathologically* considered, the difficulty is as great.

The pathological condition present in alcoholic paralysis is generally admitted to be a peripheral multiple neuritis. The cord is not diseased. Our knowledge, on the other hand, of the pathological condition present in arsenical paralysis is very imperfect. About the only information we have is derived from the experiments of Popow,<sup>4</sup> of St. Petersburg, on rabbits. According to these experiments, in acute cases, when death ensued in the course of a few hours or at the end of from three to six days, the effect of arsenic is limited to the anterior gray matter of the spinal cord. There is found a polio-myelitis. The white matter and the peripheral nerves are unaffected. In chronic cases, wherein death ensues in the course of three months, the inflammation is more diffuse, affecting the white as well as the gray matter, especially the postero-lateral columns. The spinal nerves were entirely unaffected even in these cases.

Freysing on the other hand claims that he has found all these changes in the spinal cords of healthy rabbits, while in six rabbits which had been poisoned by

arsenic he found no pathological changes whatever in the cord. Dana, in the January number of *Brain*, states that according to Pistorius, the nervous system of rabbits and guinea pigs is very sensitive to arsenic, while that of cats and dogs is less so. Jaeschke, too, found only a few small hemorrhages in the spinal meninges<sup>5</sup> of a dog which developed paralytic symptoms after a fatal dose of arsenic. Very little can consequently be inferred from experiments on animals, and we do not find that any examinations have been made on man after death to determine this point.

As has been said, the symptoms are very similar to those from alcoholic paralysis, which is known to be due to multiple neuritis. On the other hand, a diffuse inflammation of the cord would also explain the symptoms.

It may be, as is most probable, that both cord and nerves are affected in severe cases. At any rate, if the case we are discussing had ended fatally, and had come before a jury, whatever any one's individual opinion may have been, it would have been very difficult to convince the jury, that, notwithstanding the known ingestion of arsenic, a certain portion of the victim's condition was not due to alcohol, and even that this might not have been the exciting cause of his death. There is reason to believe that there were experts ready to take the stand and testify to this opinion.

This complication is likely to arise again in other cases. A decision under such circumstances can only be arrived at by extending our knowledge of the action of arsenic on the spinal cord. It is to be hoped that pathologists and medical examiners in the future will at the first opportunity make investigation into this matter and thus increase our knowledge.

Dr. E. N. WHITTIER said that the position in which he appeared in this Society to speak upon the case presented at this time, is vastly different from that which he feared for many months he would be called to occupy in the courts. He said that he was waited upon, at his office, by a gentleman of most prepossessing appearance and pleasing address, who requested that he should accompany him to the house in which the patient was at that time staying, and give his opinion upon the condition from which the patient was suffering. The account of the case, as given by the messenger on this occasion, was full of conflicting elements, and calculated to mislead one as to the cause of the illness. Four causative possibilities were mentioned, namely, alcohol, syphilis, diarrhoea, and malaria. By these means the judgment of Dr. Whittier was handicapped, and, under these conditions, he saw the patient. He had no difficulty in recognizing the paresis; the enlargement of the liver was also sufficiently evident, but the reported irregular increase and decrease in size of this organ was not compatible with any of the recognized views in the pathology of either of the conditions mentioned as possible causes of the patient's condition. Dr. Whittier then inadvertently committed himself to an opinion that it would be exceedingly difficult to obtain sufficient evidence to secure a conviction in the case.

Dr. P. C. KNAPP asked the condition of the mental faculties, and the location of the paralysis in the patient.

Dr. CUSHING replied that the mental condition of the patient was unimpaired, and his faculties were

<sup>2</sup> Further Observations on Alcoholic Paralysis. *Brain*, January, 1886.

<sup>4</sup> Ueber die Veränderungen im Rückenmarke nach Vergiftung mit Arsen und Blei. *St. Petersburg. M. d. W. Zeitschrift*, 1881, No. 36.

<sup>5</sup> Virchow's *Archiv*. Bd., 162, 1885.

clear. He could remember the main events in his past life, confessed to the abuse of alcohol, remembered the jelly which had caused the relapses in his illness, and could state who had given him that delicacy. For a time he was kept in a house of ill fame on Hudson Street, and from this quiet retreat he was brought, on several occasions, to the residence of his "friend," on Beacon Street, to dine, and was then afterward restored to the caresses of his fair entertainers at the before-mentioned brothel.

Dr. BOWDITCH asked if it were possible that the arsenic could have been absorbed into the system of the patient from the papers on the walls of the rooms he had occupied in the house in which he was stopping.

PROFESSOR WOOD stated that the papers were examined, and were found to contain no arsenic. The amounts obtained from the vomitus and from the urine of the patient were much greater than would be obtained from chronic poisoning by absorption from the wall-papers, the quantity ranging from one-fourth to one-third of a grain on the different occasions when the examinations were made, thus showing that the arsenic must have been administered at varying times, and in relatively large amounts.

Dr. BOWDITCH asked what is the process by which the attention of the grand jury is attracted to a case of criminal nature, and how a physician should proceed in a case in which there is reason to suspect a criminal attempt upon the health or the life of another.

PROFESSOR WOOD stated that criminal proceedings are instituted by calling the attention of the district attorney to the facts in the case, which are then carefully considered by him; and if the evidence, as presented, seems to him sufficient to secure the conviction of the person complained of, the case is submitted to the grand jury. All the experts in the case are called, and after the deliberations of the grand jury, the district attorney is at liberty to prosecute the case, if, in his judgment, it is advisable to do so. The objection to commencing proceedings of a criminal nature upon insufficient evidence is that the case first goes before what is called the petit jury, and if there should not be sufficient evidence to hold the person accused at that time, the case is at once dismissed, and cannot be again called up, as a man cannot be tried twice upon the same charge. It is, therefore, considered wiser to delay proceedings in a doubtful case, in the hope that additional evidence may be procured, which can then be used in the trial, which may be commenced at any time after the commission of the deed. This way seems better than to summarily dispose of every case by the form of a trial by jury, which would effectually prevent the admission of any new evidence after the prisoner had once been acquitted.

Dr. FITZ asked if any attempts were made to suppress the publication of the facts of the case in the newspapers.

Dr. CUSHING replied that the matter was almost entirely suppressed. Most of, if not all, the newspapers had a detailed account of the case in type, and, perhaps, have it still; but the matter was kept from the columns of the press by means of threats of prosecution, so that the public never obtained the facts in the case in any degree of fullness or detail.

The next paper was by Dr. HAROLD WILLIAMS, entitled,

#### A CASE OF HODGKINS' DISEASE.<sup>1</sup>

Dr. C. P. PUTNAM presented the notes of a case recently under his care: The patient was about thirty years old; lawyer. He was unusually muscular, and could paddle a canoe for twenty miles without difficulty. He had had no illnesses of importance hitherto, except eczema, from which he had suffered throughout his whole childhood, and which had been finally cured at Hebra's Hospital, in Vienna. The only remains were an irritability of the scalp and face, and he was very little disturbed by this. He first came on the 11th of January, 1886, with one enlarged gland under the occiput, and one under the left jaw. These he had noticed about the first of January; at any rate, he was sure that, on Christmas day, he was perfectly well. Iodine was applied to these enlarged glands, and in a week they were smaller. But, meanwhile, others had appeared in the same neighborhood, which, in their turn, were treated with tincture of iodine. Ten days later he returned, with the second set of glands also smaller, but with a larger crop in various places in the neck, and also in front of the ear. Then it was found that the axillary and inguinal glands were enlarged and hard. Iodide of potassium had been given, five grains, increasing to ten, three times a day. During the next two weeks he was very much better, and considered that he was getting well. All the glands diminished in size. Meanwhile, however, the whole neck had been growing gradually, but perceptibly larger, so that his collar could not be buttoned. About the middle of February, this apparent improvement ceased. The glands began to enlarge again, and the skin became more red and tender. This time, a slight enlargement of the spleen and liver, and general fullness of the abdomen, was found. Arsenic was substituted for iodide of potassium, and with apparent good effect. He again seemed to improve, and was satisfied with his condition; voice husky. In March, however, he complained of want of appetite, and difficulty of retaining food; had to keep a pail near him, as he would vomit suddenly and violently. Was weak, and lay on the lounge much of the time; ceased to take an interest in books, although he was an active and intelligent reader. Up to this time the pulse had been normal or slightly accelerated, and there was no rise of temperature. The vomiting was supposed, by the patient, to be caused by the arsenic, which was omitted, and then given again, and again omitted.

About the 18th of March he began to lose strength rapidly; lay on the lounge all day too ill to talk, taking little food and vomiting frequently, and yet feeling hungry from time to time. Became less inclined to get up, and from about the 20th kept his bed. His mind became less and less interested in his surroundings and occasionally it would wander. On one occasion he had a hemorrhage from the bowels which was, however, easily stopped. During this period the action of the heart became more rapid, varying from 100 to 120. Respiration was superficial but not labored. He died on the 29th, one month and eighteen days after I first saw him, and almost exactly three months from the time when he noticed the first symptoms. Autopsy by Dr. Gannett.

Dr. W. W. GANNETT described the appearances found at the autopsy, made March 29, 1886. The front and lateral regions of the neck were occupied by

<sup>1</sup> See page 420 of the Journal.

numerous packets of gray, rounded nodules, varying in size from a filbert meat to a walnut; showing on section a homogeneous, and somewhat translucent appearance, like that of a lymph-gland.

Similar nodules were found in the mediastinum and about the roots of the bronchi.

The spleen was much enlarged, and contained numerous secondary nodules of lymph-sarcoma.

The kidneys and liver showed the presence of very numerous secondary nodules.

In the mucosa of the stomach and intestine were numerous, elevated nodules, varying in diameter from one to two centimeters, with depressed centres. Microscopically these showed the structure of a lymphoma.

Dr. Gannett stated that when he made the autopsy he was so struck with the similarity of the course of this case to the acute infectious diseases, the severe symptoms having lasted only three weeks, that he placed at once portions of the new-growth in alcohol for examination for microorganisms. Thin sections, made after hardening, of the gastric and intestinal nodules, stained with methyl-blue and examined with a Zeiss 1-12, showed the presence of well-marked micrococci, in colonies, in the new-growing tissue and no other microorganisms.

Of course, such a result does not prove that the micrococci found were the specific cause of the disease; since to prove this, isolation, pure cultivation and successful inoculation experiments are necessary; but it may serve as a finger point to call attention to the possibility of lympho-sarcoma being an infective disease, and to suggest the advisability of further investigation in regard to this point.

DR. HOWARD M. BUCK asked if there exist any known relation between the eczematous diathesis and the development of pseudo-lukemia?

DR. FITZ asked if Dr. Williams had compared the symptoms noticed in his case with those associated with Hodgkins' disease in the literature of that subject?

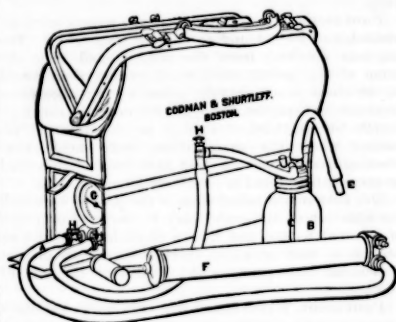

DR. FITZ remarked that in the account presented by Dr. Williams, there is a much greater similarity to the clinical appearances of multiple sarcoma, than to those of Hodgkins' disease.

DR. KNIGHT asked if the patient began to improve before the administration of arsenic was commenced.

DR. WILLIAMS replied that there was improvement, but that the urgent symptoms then consisted of appearances simulating paralysis of the legs, which was considered to be due to the existence of large masses of indurated glands within the abdominal cavity, which were pressing upon the ganglia or nerve-trunks distributed to the lower limbs.

DR. F. C. SHATTUCK said that the remarks of Dr. Fitz put him in mind of a case which he had reported a year or two ago, and which certainly was somewhat similar to that of Dr. Williams. The case was published in the *Boston Medical and Surgical Journal*, under the heading of multiple sarcoma of the skin. Recovery under arsenic hypodermically. The patient is at present quite well. The tumors were to be numbered by hundreds, had in places coalesced into great patches, and the skin over many of them was discolored in the way described by Dr. Williams. The only glands which were distinctly enlarged were those at the angles of the jaw. In reply to a question of Dr. Shattuck, Drs. Putnam and Williams answered that no tenderness over the sternum or the shafts of the long bones had been noted in this case.

DR. E. W. CUSHING recognized the similarity of the cases of Hodgkins' disease to some cases recorded in literature as multiple sarcoma, and stated that micrococci, and also bacilli were found in the tumors and also in the organs in a case of Hodgkins' disease by Italian observers as published in 1886, in the *Gazetta int. delle Scien. Mediche*. From the presence of these organisms in the tissues is it not possible that there may be an error in the conception of the nature and origin of multiple sarcoma. Certainly in no other known form of sarcoma is recovery thought to be possible. May there not be an error also in the diagnosis of many cases of the so-called sarcomata in other portions of the body?

LARYNGOLOGICAL HAND-BAG.

DR. T. A. DEBLOIS exhibited a new form of physician's hand-bag, which he had recently had made. It consists of an ordinary leather bag, of medium size, but is about one-third deeper than the ordinary bags. At one end of the bag is an opening near the bottom, which can be closed by a flap which buckles tightly. This opening displays the end of an air-condenser, with two cocks, and a pressure-gauge. In the bag can be carried a small pump, by which the air can be forced into the condenser. In the space of two minutes Dr. DeBlois was able to obtain a pressure of thirty-five pounds to the inch without great exertion. The apparatus is then ready for use as a spray for the throat, the use of the Evans' inhaler, or for any other purpose to which this treatment is applicable. The bag is sufficiently capacious to accommodate all the articles usually required. The weight is not materially increased by the addition of the condenser, and the whole apparatus is not too heavy to be easily taken in the hand when walking. It is manufactured by Messrs. Codman & Shurtleff.

#### FINANCE.

DR. V. Y. BOWDITCH submitted a report for the Committee on Finance for this Section. He stated that the Committee had secured the necessary amount of money for the reimbursement of the Secretary for the money spent during two years on account of the Section, and added that it was the opinion of some of the members of the Section that any further expense for the purposes of entertainment after the meetings was not expedient. He hoped that the Section would express its sense upon the subject.

DR. H. I. BOWDITCH stated that he knew something of the difficulty of collecting funds for social entertainment. The entertainments of the Medical Society were inaugurated some years ago, when the Suffolk District Medical Society first began to hold its meetings. There was a disposition on the part of the other Societies to sneer at the Suffolk District, and to ridicule the idea of such gatherings for medical improvement. Dr. Bowditch proposed that if the Society could not come together for medical improvement, it could at least come together in a social way, and thus obtain some benefit from the better opportunity afforded for acquaintance and intercourse. The collation was introduced for that purpose, but the Society has long outgrown the need for any such artificial aid in the prosecution of its legitimate work; its meetings are well attended, by those who are not attracted by the prospect of a collation, and this element is no longer essential to the successful working of the Section. Dr. Bowditch moved that any collation at the close of the meetings be abandoned.

DR. CUSHING said that he could not agree with those who would dispense with all forms of entertainment after the meetings. He said that he could hear as good papers in other places as in these meetings, and we have the opportunity to read them in the medical journals, afterward. It is not that alone which makes a meeting useful; it is to fully as great an extent the mutual opportunity for meeting all together, and interchanging ideas and opinions in the social way of conversation after the regular exercises are concluded. Too great weight cannot be laid upon the advantages accruing to the physician from a better acquaintance with and a higher appreciation of his professional brethren. Most if not all of the dissensions which exist between medical men to the disgrace of their profession would be avoided if the men only came more freely together, and thus understood each other better. Dr. Cushing expressed the hope that the members of the Section might still have the opportunity to occasionally pass a few minutes together after the meetings, a privilege which he highly valued, and one from which he had derived both pleasure and profit.

DR. HAROLD WILLIAMS moved that the Section apply to the General Society for the necessary funds to provide a simple entertainment at the close of the meetings. The Secretary stated that the Section has appealed to the General Society for aid, but the appeal was always in vain. The General Society would not contribute toward these expenses of the Section.

#### NASAL POLYPUS.

DR. J. W. FARLOW showed a large nasal polypus, which he had recently removed. The growth filled the nasal space almost completely, and protruded into the pharynx, where it was plainly visible. It was removed entire by means of a sling.

DR. BLODGETT asked the histological structure of the growth, if it was a simple hyperplasia, or if it partook of the nature of a heterologous formation? He wished to ask the reader if these larger polypoid growths are ever the seat of origin of the sarcomata which are occasionally met in the interior of the face, in the antrum, in the orbital region, and elsewhere about this region. Dr. Farlow said that these growths are usually of benign character, and do not occasion

any suspicion of malignancy. They consist of hypertrophied mucous tissues, and are removed more from the disturbance in articulation, and from their tendency to invade other parts than from any fear of malignancy.

#### SUFFOLK DISTRICT MEDICAL SOCIETY. SECTION OF OBSTETRICS AND GYNÆCOLOGY.

ROBERT B. DIXON, M.D., SECRETARY.

FEBRUARY 16, 1887, DR. JAMES R. CHADWICK, in the chair.

DR. J. B. SWIFT reported,

#### A CASE OF ALEXANDER'S OPERATION.<sup>1</sup>

DR. FARLOW asked why Alexander's operation was performed before restoring the perineum. He thought that in cases where there was a cystocele or rectocele of any extent, the want of the supporting perineum would allow a still further descent of the vagina, tending to pull with it the uterus and to stretch the round ligaments. For this reason, operation on the perineum might prevent the necessity for an Alexander's operation, whereas, if the latter operation were done first, the operation on the perineum might subsequently be necessary.

DR. SWIFT said that so far as he knew, in cases of prolapse, the operation of narrowing the vagina had not been very successful, the uterus descending again after a while. He thought the operation of shortening the round ligaments was a less severe one, and so far, the cases reported had been more successful in the result, though he had seen no reports of cases later than two years after the operation.

DR. SINCLAIR expressed the opinion that these uterine ligaments might elongate again after Alexander's operation, even when for some time the results have been beneficial. He said that there are many operations, which are highly praised for a time, but are soon given up because they do not do the good claimed for them.

DR. VICKERY asked how much shortening of the ligaments was necessary.

DR. SWIFT replied that the amount of shortening was not accurately measured. He drew on the ligaments until the uterus was in good position and then secured them. For some reason there seemed to be considerable opposition to the operation in Boston. He only knew of four cases having been done here. Dr. Polk, of New York, had probably had more cases than any one else in this country. He had reported fourteen cases, all of which had been successful, and in speaking of those operators who had failed to find the ligaments, he thought the reason of their failure was that they had not found the ring.

DR. JOHN HOMANS, 2d, showed a

PIRROID TUMOR OF THE UTERUS, REMOVED BY DR. JOHN HOMANS, FEBRUARY 12TH, BY HYSTERECTOMY.

The patient, who was kindly referred to Dr. Homans by Dr. W. H. Baker, is fifty-one years old, and dates all her trouble from an accident which happened twenty-seven years ago, while she was pregnant. A difficult labor (non-instrumental) and slow recovery followed. Since then her history has been in brief, that of excessive flowing and constant pain during the

<sup>1</sup> See page 421 of this number of the Journal.

periods. During past four years catamenia once a fortnight lasting three or four days; seventy or eighty napkins used. In 1882, Dr. Baker found a fibroid size of cocoon to which he made one application of electrolysis. Masses of fibrous tissue were passed per vaginam, the patient was relieved and the tumor disappeared, only to reappear within a year larger than before, with former symptoms much aggravated.

The patient—now very anæmic from frequent hæmorrhages, with a feeble pulse, mitral regurgitant murmur, one-eighth per cent. albumen in urine, and considerable œdema—requesting operation, hysterectomy was accordingly done. The tumor was lifted out of the abdominal cavity, Koeberlé's serre-nœud passed round it, and after amputation the stump was treated extra-peritoneally, the wire remaining *in situ*. Weight of tumor removed, seven pounds. Length of uterine cavity removed, five and one-half inches. Patient was very weak for a day or two, with pulse of 140, but soon improved. Wire and clamp came away on February 16th, and patient is now on sure path to recovery.

DR. MARCY, in the discussion of the treatment of the pedicle after hysterectomy, or the removal of uterine myoma, gave a brief account of the method which he had pursued for a number of years.

A pure gum-rubber sheet with a central opening reinforced, to prevent the slipping of the ligature, as well as tearing, is carried down over the growth upon the pedicle and constricted by two or more turns of rubber cord. Then the tumor is cut away without loss of blood, except the emptying of the divided veins, or defilement of the abdominal cavity and contents, thus protected by the rubber. Dr. Marcy was led to the use of rubber from the observation of the dentist's use of the so-called "rubber dam."

In order that the hæmorrhage might be held in control and yet not constrict, to cause sloughing, Dr. Marcy devised the use of the so-called "shoemaker's stitch." The suturing is effected with a needle set in a handle, the eye near the end, which is without a cutting point, and which carries a chromicized tendon threaded from opposite ends back and forth through the same puncture. Thus the stump is divided by as many stitches as may be preferred and the ends secured by only one knot.

It is important not to constrict too tightly, and it is noteworthy how easily all hæmorrhage may be controlled by suturing in this way; since there is no possible escape from an even and uniform compression of all the tissues. In the use of animal ligature an important point gained, is to reduce to the minimum the number of knots, and this is secured by any form of continuous suturing.

It is important to cut the stump above the line of constriction, in flaps which will readily coapt and, if the uterine canal is involved, to curette away the mucous membrane as a farther safety from infection.

The peritoneal surfaces are then brought together carefully, and retained by a fine over-and-over animal suture. By this method the operation can be safely done under irrigation with mercuric-bichl. solution, to say the least, usually ill-advised in laparotomy without the protection of the abdomen and its contents by the rubber sheet.

The advantages gained by this method are:

I. The reducing to the minimum the loss of blood and easy and safe control from hæmorrhage.

II. A thoroughly aseptic operation, with protection of the abdominal cavity and its contents.

III. The intra-peritoneal treatment of the stump and complete closure of the abdominal wound without drainage.

In Dr. Marcy's judgment the importance of the last cannot be overestimated. Hand in hand with the perfection of antiseptic measures came the intra-peritoneal treatment of the pedicle of ovarian tumors, and few would now for a moment advocate returning to the use of the clamp. Much more important is the intra-peritoneal treatment of the stump after hysterectomy. This is constricted so as to control hæmorrhage, but not necrosed, is covered with peritoneum, and leaves no open surface for absorption.

DR. JOHN HOMANS, 2d, said that Dr. John Homans usually uses the needle for the stump of fibroids. Then aseptic gauze is used and the stump is kept covered with liquor ferri persulphatis, and thus there is no suppurative process, but a sort of dry gangrene, and the stump comes away shrivelled and dry in four or five days. If death is to occur, it is generally from exhaustion or shock within thirty-six hours, instead of septicæmia.

DR. CHADWICK said that Tait used two needles, thrust through the stump, on either end of which were affixed a flat plate which rested upon the abdominal walls and prevented the end of the stump from sinking within the abdominal cavity. The end of the stump was charred by the hot iron or perchloride of iron so as to be perfectly dry. The abdominal wound was sewed tightly round the stump so that agglutination took place long before there was any suppurative or exudation from the stump. This agglutination seemed to be effectual in preventing the entrance of any fluid into the peritoneal cavity, and would thus render Dr. Marcy's ingenious rubber dam superfluous.

Dr. Chadwick said that the operation of anterior colporrhaphy, as described by Dr. Cushing, was well known in Boston; he had often seen it done in the Massachusetts General Hospital, where he was House Surgeon in 1871. Dr. Chadwick had never done any other operation himself; he, however, dispensed with the multiplicity of details and instruments recounted by Dr. Cushing. Dr. Chadwick's operation was simply to cut a hole in the vaginal wall behind the urinary meatus, through which blunt-pointed scissors were thrust between the vesical and vaginal walls, opened widely and withdrawn several times, by which manœuvre the adjacent walls were dissected apart without the use of a cutting edge. The minimum of bleeding was thus secured, and the only danger of the operations—wounding of the bladder, absolutely avoided. When the dissection is completed, the vaginal wall is slit longitudinally from the original opening nearly to the vaginal portion, and consecutive slices cut from either side of the incision until an oval opening in the vaginal wall is left. The denuded surface is then thoroughly disinfected, and the edge of the wound approximated by interrupted silk sutures; these are introduced very near together and very superficially, so when suppurative sets in on the sixth to eighth day, very little traction upon the free ends of the sutures, protruding from the vulva, will cause the sutures to cut through and come away. Dr. Chadwick has been in the habit of operating upon the lacerated cervix, the anterior vaginal wall, and the posterior

vaginal and perineum at one sitting, with perfectly satisfactory results.

Dr. Chadwick said that when he was studying in Breslau in 1873, Professor W. A. Freund had conceived the idea of Alexander's operation, and they had together made several experiments upon the cadaver, to determine its practicability. They had never failed to find the ends of the cords, but after dissecting them up and drawing upon them; they had never been able to draw them down more than two inches, which had not been found sufficient to raise the retroverted fundus; moreover, the peritoneum investing the cord was drawn down into the canal of Nuck in such a way as to suggest liability to inflammation of that membrane. These considerations had caused them to abandon the operation. Recent experiences have made evident that the agglutination of the peritoneum to the cords is a post-mortem change, and not an obstacle to the operation upon the living. Dr. Chadwick went abroad last summer with the intention of seeing some of Alexander's operations, but found the leading gynecologists of England so opposed to the operation that he renounced his intention. The objections raised were: (1) the occasional impossibility of finding the end of the cords; (2) the serious results and even deaths that had followed the operation, and more important than all, (3) the fact, as alleged, that the relief to the displacement was but temporary. Dr. Swift's result was certainly very good, and would encourage him to try the operation.

DR. HENRY O. MARCY read a paper entitled  
THE PERINEUM, ITS ANATOMY, ITS LESIONS AND  
THEIR RESTORATION.

It was illustrated by a large collection of photographic pictures projected upon the screen, a considerable number of photographs of patients, showing different degrees of injury, and in varying stages of operation for restoration.

As shown by a number of actual dissections, the anatomy of the perineum is quite different from the teachings of the ordinary text-book, and this is the more remarkable since, as shown by photographs from the celebrated drawings of Wm. Hunter, this master clearly taught some of the important relations of the muscles going to make up the floor of the pelvis.

In rupture, not involving the sphincter ani, the divided ends of the transversalis retract, and this pulls apart, or allows the separation of the lateral closure of the vulva and permits the eversion of the antero-posterior folding of the vaginal muscle. Thus weakened, the usually closed, elastic, vaginal column of support to the uterus, fails of its normal function and the entire train of evils, dependent upon misplacements and disordered pelvic circulation and nutrition, may follow.

A long continuance of these factors may so change the floor of the pelvis as to render its complete restoration impossible, and it is important to recognize and restore the injured parts as early as possible. This should be done at once after the injury, but for manifest reasons a large number of cases will escape the obstetrician.

Dr. Marcy's method of restoration is too well known to require a detailed description. The patient, in lithotomy position, he dissects carefully, with two fingers in the rectum, the posterior vaginal wall on a plane with the sphincter ani and rectum, by introduc-

ing midway a sharp-pointed double-edged knife. The dissection is carried laterally as far forward as the cicatricial marks show the injury extended, and above to a point determined by the conditions of rectal dilatation even, if desired, to the extent of a posterior colporrhaphy. The vaginal flap is then lifted anteriorly, the divided ends of the retracted transversalis are felt for and coapted by a deep tendon suture, which is repeated as a deep-buried continuous stitch, as may be thought needful.

Dr. Marcy considers the use of the interrupted stitch for the closure of the perineum, even of wire, although almost universal, as very defective, and attributes to it a large share of the failures which so commonly follow. No matter how inserted, or how much tissue enclosed, it is a loop and must act equally upon the part enclosed. In order to prevent traction from above downward, and secure a lateral coaptation, with rest and retention, Dr. Marcy has devised a double pin, the halves of which are nearly alike. It is made of German-silver wire, gauge No. 20 or 22, because this material does not irritate the tissues and possesses stiffness and elasticity, qualities which are essential. The end is bent in a small loop and turned one-fourth of an inch therefrom, at a right angle, and the shaft is two or two-and-a-half inches in length, and sharpened like the point of a subcutaneous syringe. The one-half is introduced from within the vagina outwards, chiefly laterally, the direction being determined by the finger in the rectum, to which the pin should be parallel.

The other half of the pin, similarly constructed, is introduced upon the opposite side, from without inwards, the point of which is caught in the loop of the first part and adjusted without. Thus a kind of "safety-pin" is constructed and when fitted to retain properly the enclosed parts, the loops are clamped down by compression forceps and the ends cut square. Perforated shot are sometimes used to protect and strengthen. If properly adjusted the elasticity of the wire allows for the lateral oedema and does not impede the circulation in the enclosed parts, while complete approximation is obtained and no force is exercised in the direction of the long axis of the triangle.

The wound, thus closed, may be rendered and retained aseptic. It is protected from vaginal secretions, as the vaginal surface is not injured and the open wound is reduced to the short side of the triangle, which is carefully closed by an over-and-over animal suture. Usually two pins are sufficient. The bowels are kept open. The eighth or tenth day, each pin is gently pushed upwards, and the vaginal end exposed. Each side is then cut off near its juncture and withdrawn. The animal sutures are not disturbed.

In cases of complete laceration, involving the sphincter ani, the method of dissection is much the same. It is carried laterally, on each side, as far as deemed necessary. The rectal surfaces are first refreshed and coapted by animal suture, the vaginal next, and the triangle is then not unlike the conditions where the lesion is only partial. Greater care must be taken to avoid rectal accumulation. Dr. Marcy has now operated in this manner over fifty times and with such excellent results, that, in many instances, it would be difficult to determine if a lesion ever existed.<sup>1</sup>

<sup>1</sup> The pins are kept in stock by Codman & Shurtleff, of Boston, and Tiemann & Co., of New York.

## NEW YORK NEUROLOGICAL SOCIETY.

STATED meeting, April 5, 1887. The President, C. L. DANA, M.D., in the chair.

## REPORT OF A CASE OF SARCOMA OF THE BRAIN: OCCIPITAL LOBE, CAUSING HEMIANOPSIA. REMOVED BY OPERATION,

by DR. W. R. BIRDSALL and DR. R. F. WEIR.

DR. BIRDSALL gave the history of the case, of which the following is an abstract. The patient, a Hebrew, aged forty-two, first came under his observation October 16, 1886. He had always been healthy until the summer of 1885. He denied injury to the head, or venereal disease. In August, 1885, he observed, for the first time, unsteadiness of gait, and had a severe attack of vomiting. Soon after diplopia for distance and increased awkwardness in walking was observed; also a disagreeable sensation, akin to numbness, in the right leg, hand and shoulder, but not in the face. This and the diplopia were transitory. Headache, usually frontal, was present occasionally, but never severe. October 7, 1885, he consulted Dr. E. C. Seguin, who found the eye muscles normal; no diplopia with red glass. Left pupil a trifle wider than right, both active, fundus normal. Left lateral hemianopsia, vertical line passing little to left of fixation point. No paresis of tongue, face, or limbs; no anesthesia; patella reflex normal; walk somewhat swaggering, with decided tendency to the right. October 20th, diplopia had recurred; left externus weak; hemianopsia the same; no hemiopic pupillary reaction. Grasp of right 42°, left 30°. November 7th, beginning neuro-retinitis. Drowsiness during the day. Difficulty in rising from chair.

*Diagnosis.* Tumor of mesal aspect of right occipital lobe, involving primarily the cuneus, extending downward toward the tentorium cerebelli, and perhaps also upward toward the para-central lobule leg centre.

*Treatment.* Large increasing doses of potassium iodide.

From January to July, 1886, patient under care of late Dr. McBride. During the early months of this period his diplopia disappeared and never returned; his gait improved somewhat, but he had two attacks on street, feeling he could proceed no further, and staggered toward the left. From September on his difficulty in rising, standing, and walking, together with drowsiness rapidly increased. In October, 1886, Dr. Birdsall found double optic neuritis, most marked in left eye; left pupil somewhat larger than right, no diplopia, no ocular paresis evident. His movements were clumsy rather than ataxic, at times being accurate, at others wide of the mark, especially in left extremities; gait slow and uncertain. There was frequent expectoration of a viscid saliva. Left hemianopsia, Dr. Birdsall thought, could be accounted for only by a destructive lesion in the neighborhood of the gyrus cuneus of the right occipital lobe. The locomotory disturbances appeared to him to be due to pressure effects of a tumor on structures below the tentorium; thus implying a growth of considerable size. His disturbance of equilibrium continued to increase in a very irregular manner. His intellect was not impaired. His family observed no change in his character or disposition. He was extremely uncomfortable mentally. An operation was proposed in February, 1887.

The operation was performed by Dr. Weir. Regarding the tumor Dr. Birdsall said it was of so large size, so much of the occipital lobe was compressed by it that the case was of little value for determining the limitation of the visual area in the occipital lobe. The growth was a sarcoma, originating in the meningeal structures, producing destruction of the cerebral tissues by pressure alone. Absence of severe headache should be noted, as it is usually a prominent symptom of tumors involving the meninges. One of the most important lessons that the study of cerebral tumors taught was that growths remaining limited to the meninges may attain a large size before disturbing the function of neighboring parts of the brain. In these cases regions away from the tumor may give signs of importance before those in contact with the tumor. The extreme fatality of intracranial neoplasms was high warrant for taking an extreme surgical risk. The coöperation of neurological science and surgical art in the present state of each could hardly fail to build up an experience which would in some cases save life that would otherwise be lost.

Dr. WEIR described the operation which was performed March 9, 1887. Special antiseptic precautions prior to and during the operation were taken. The periosteum was raised, two openings were made with the trephine, the first one inch above the occipital protuberance, and the same distance from the median line; the other immediately above. The openings were joined, and enlarged by the Rongeur forceps to two and three-fourths, by two and one-fourth inches. The dura mater was divided two-thirds the extent of the bone opening. Its retained attachment being toward the median line. The tumor was at once recognized and enucleated. It was necessary on account of its large size to incise it and press out some of its substance before it could be completely detached and removed through the opening. A great deal of venous bleeding took place, and sponges were stuffed in for temporary pressure, the cavity was inspected by the electric light, and showed that great amount of pressure had been exerted upon the brain; the falx was crowded to the left of the median line; the tentorium was depressed to a horizontal line. The tumor weighed five and a fourth ounces. It measured three and a fourth by two and three-fourths by two and one-half inches. One of the bleeding points was found to be in the region of the straight sinus, not free enough to be from that vein, but probably from the pedicle of the tumor; the other, apparently arterial, probably from a terminal branch of the posterior cerebral artery. The flow from each was readily checked by direct pressure, and it was determined to control them by packing the cavity with iodoform gauze. The dura mater was partly united over the gauze by loose sutures. The operation was well borne until the final enucleation of the tumor, when the pulse fell, apparently from loss of blood. Some hours afterward slight diverging strabismus of the left eye was noticed; blood stain appeared through the dressings; the pulse was weak; stimulants were given; the patient was restless. At night transfusion of a saline solution was made with temporary improvement, and the dressings were removed to control hemorrhage, which was seen to be taking place in a small stream, but the pulse again gave out, and nothing further could be done than re-apply pressure in the supposed direction of hemorrhage. Death occurred at 2 A. M.

An autopsy was not allowed, but in the lower part of the brain cavity was seen a large collection of coagulated blood.

DR. WEIR said that in another case, where the hemorrhage was from vessels too deeply situated to apply a ligature, he would control it by leaving on clamp forceps, to be removed after a period of twenty-four or forty-eight hours. The opening, although large, was not sufficiently large to enable him to remove the tumor entire. It was intended to adopt Macewen's method, and employ bone grafts. Dr. Weir had recently replaced the pieces of bone removed by the trephine in a case of epilepsy, the opening being nearly two and a half by three inches, and now, about seven weeks after the operation, the wounds had healed save one, and the bones were felt to be solid, and were painless. Brief references to the cases of tumors of the brain for which operations had been performed were made.

#### REPORT OF A CASE OF CYST OF THE BRAIN, WITH OPERATION.

DR. GRAEME W. HAMMOND related the case. The patient, a married woman, complained of severe pain an inch above the right ear, and had left hemiplegia. At the time her symptoms began, she was about twenty-nine years of age; she had had four children, and during the progress of her disease she had a fifth child. All were strong and well. Her sickness lasted about two years and a half. It commenced by sudden loss of consciousness and convulsions limited to the left side. The left side of the face became, and remained, paralyzed. About a year later she noticed gradual loss of power in the left arm; things dropped from the hand. At the end of another year the left arm was completely paralyzed. She then noticed increasing weakness in the left leg. When Dr. Hammond first saw her she was able to stand and walk slowly. While the paralysis was extending she had four or five epileptic seizures, confined to the left side. Headache developed about the time the legs became affected, grew more constant, and was described as agonizing.

She denied syphilis. Physical examination showed loss of motion on the left side of the face, tongue, and soft velum; of the left arm, and partial loss of motion in the left leg. There was no disturbance of sensibility of any kind. The reflexes were exaggerated on both sides. Sight, hearing, smell, and taste were normal. Choked disc on both sides was observed at a subsequent examination.

Under treatment, the headache was controlled to a considerable extent. Dr. Hammond's diagnosis was probable cerebral tumor involving the cortical or sub-cortical substance of the motor centres. An operation was refused. The patient grew worse until the 20th of March, 1887, when her husband asked that the operation be performed. Dr. Spitzka then saw the patient with him, and made two examinations. He rather coincided in the diagnosis. The operation was performed in the hospital last Wednesday. Dr. H. Josiah Roberts assisted at the operation, removing the portion of skull by his electro-osteotome. Four buttons were removed by the electro-trephine; these were connected by straight lines made with the circular saw. The diameter of the opening was over two inches. A crucial incision was made through the dura. A hypodermic needle was introduced in different directions, but no fluid was withdrawn. The dura was

closed, a drainage-tube was introduced, the skin-flaps were sewed up, the patient was put to bed. She lived only twenty-one hours, remaining unconscious after the operation. Prior to the operation she had become completely paralyzed in the left lower limb; she had delusions and hallucinations, she talked incoherently. Bed-sores developed.

The autopsy showed little hernial protrusion at the wound; the cortical substance here was thin. Incision through the motor region revealed three cysts in a line, deep in the white substance. The fluid in the cysts had been only partially examined; it was serum, and contained broken-down brain substance. The cysts were close together, and in a position to affect the face, arm, and leg centres. He could not explain why the syringe failed to bring forth fluid, unless it was that the cysts were too deeply situated, or the needle passed between them. He added to the clinical history that the head was drawn to the right side the last three days of life.

DR. E. C. SEGUIN was partly responsible for the operation in the first case, but it seemed the patient would not live more than two or three months without it. He expected to find a large tumor, but was somewhat surprised to see it encapsulated and non-parenchymatous. During the early history of the case the symptoms pointed to destruction of brain-tissue. He asked Dr. Hammond whether the sensory or motor symptoms determined the seat of his operation.

DR. HAMMOND replied that the headache corresponded to the centres for the motor systems, and the seat of the operation.

DR. SEGUIN added that the seat of the pain would be a very uncertain indication for the seat of the operation. In some cases of cerebellar tumor, for instance, the pain had been mostly frontal.

DR. E. C. SPITZKA, referring to the case reported by Dr. Birdsall and Dr. Weir, said that an artery, large enough to cause fatal hemorrhage, entered the gray and white substance of the right occipital lobe. It had been overlooked in many text-books.

DR. ROBERTS explained how the circular saw could be used without injury to the brain, and the operation of the electro-osteotome.

DR. STARR suggested the desirability of an analysis of reported cases of cerebral tumors, for the purpose of determining their rapidity of growth and size.

DR. R. L. PARSONS read a paper entitled

#### NOMENCLATURE IN PSYCHIATRY. MONOMANIA OR OLIGOMANIA, WHICH? PARANOIA, WHAT?

An examination of the reports of fifty-one asylums for the insane, taken at random, showed that of the whole number of patients enumerated less than two per cent. were classified as cases of monomania, while in twenty-four of these reports the term did not appear. But, however much systematic writers on the subject of insanity deprecated the use of the term monomania, they rarely succeeded. There were manifestations of insanity which were neither melancholia nor dementia, but which differed so much from mania that another designation was required for them, and the objectionable term monomania was the only one generally employed. Dr. Parsons thought a suitable substitute could be found. Paranoia had been used to a considerable extent, but if the meaning of the term monomania was too narrow for the purpose required, that of paranoia was too broad. In conclusion, then,

with the assumption that monomania, as defined and explained by certain writers on psychiatry, designates phases of insanity of sufficient importance and well enough differentiated to require a place in the general classification of mental diseases; and with the further assumption that the reasons adduced in this paper are sufficient to justify the substitution of the term oligomania for monomania, it only remains to apply the proper meaning of the latter term to the former, to wit: a form of insanity which, although potentially affecting all the mental faculties and operations, apparently involves only a part, as the intellect, the emotions, or the will, or certain manifestations only of a faculty of the mind; which originates in the intellectual faculties rather than in the feelings; and the manifestations of which are well-defined, persistent, dominant, and systematic in character.

### Recent Literature.

*A Text-Book of Pathological Anatomy and Pathogenesis.* By ERNST ZIEGLER. Translated and edited for English students by DONALD MACALISTER, A. M., M.D. Part II. Special Pathological Anatomy. Sections IX-XII. New York: MacMillan & Co. 1886.

This completes a work, the previous parts of which have already been noticed in the JOURNAL. These sections contain a description of the changes found in disease in the urinary and respiratory organs, and in the central and peripheral nervous systems. These subjects are carefully treated and well illustrated. They all bear the impress of original work, especially the section devoted to the kidney. And this, perhaps, is the only criticism that can be made against the work: that, for a text-book, it has too much individuality, and, therefore, does not give quite enough value to the views which have been more generally received. The abundant references, both to German and English literature, aid in correcting this fault, however, but are of greater value to the advanced student than the beginner. We can most heartily recommend the book to the profession, and prophecy for it as great a success here as abroad.

#### *Tenth Annual Report of the State Board of Health of New Jersey.*

This report contains the report of the Secretary, Dr. E. M. Hunt, followed by several papers upon various important topics relative to Public Health.

Of these, two are especially worthy of comment. "The Hygiene of Occupations" by Drs. Hunt, Stickler, Newton and Davis, forms a valuable contribution to the literature of this important subject. The occupations considered are glass and iron workers, hatters, workers in silk, jute, flax and rubber. The statistics relative to hatters are carefully compiled, and data are presented relative to the prevalence of certain diseases, such as catarrh, lung-disease, rheumatism, etc., among them.

The paper upon "Illuminating-Gas" by Dr. J. H. Raymond, of Brooklyn, New York, deals with a subject of considerable importance, but in such a manner as to elicit an inquiry as to its "raison d'être" in a sanitary report. The main portion of the paper relates to the history of illuminating-gas, processes of manufacture, etc., while the dangers from gas-inhalation are hastily disposed of in a few closing para-

graphs, and the comparative dangers of the two principal gases now used in some of the large cities of the United States are entirely ignored.

It is quite remarkable that the writer should not have found out, after the very elaborate report which he had made to the City Government of Brooklyn, that the fatality from gas-poisoning in his own city and in New York had increased ten-fold since the introduction of a more poisonous gas, the same being also true in regard to Baltimore, Rochester, Toronto, and other American cities.

*Nervous Diseases and Their Diagnosis.* By H. C. Wood, M.D., LL.D. 8vo. pp. 501. Philadelphia: J. B. Lippincott Company. 1887.

The author of this work sees fit to apologize "for again trespassing upon the patience of the profession." Such an apology, which would hardly be warranted when we recall the value of the author's previous work in this department, becomes still more unnecessary from the fact that, in spite of the number of new books on nervous diseases, there is no good work in English on the special subject of diagnosis, except the manuals of Gowers, which cover but a part of the ground. The volume before us, therefore, is a distinct help to the student, and is a necessary supplement to the systematic works on diseases of the nervous system.

The first four chapters are devoted to motor symptoms — paralysis, motor excitations, reflexes, and disturbances of equilibration, — then, after a chapter on trophic lesions, sensory paralysis, exaltations of sensibility, and disturbances of special sense each form a chapter. Disorders of memory and consciousness, disorders of consciousness, and disturbances of intellect are discussed in the last three chapters. The arrangement of subjects under the several headings is systematic and clear. We feel grateful to the author for considering all the diseases of the brain in the various chapters, the insanities as well as the forms of brain disease commonly treated in our text-books, — and for devoting a special chapter to the subject. Such a course must be a great help to the student, who too often overlooks the facts that mental and nervous diseases cannot be separated by any distinct line. Pathology as a rule is subordinated to diagnosis in the work, but occasionally, as in treating of chorea, the author dwells at length upon the pathology, giving us the substance of his own former researches.

A few statements merit a word of criticism. The author's experience in finding the patellar reflex absent in hysteria is certainly unusual, and we would regard the absence of the reflex in health as an event much more rare than the figures show that the author quotes. In progressive muscular atrophy, too, reaction of degeneration is not uncommon, even in the early stages. The section on Thomsen's disease is far behind our present knowledge, and the section on aphasia seems to us a little brief and obscure. Singularly enough the author omits to speak of neuritis as a cause of paresthesia. An explanation of the lettering of some of the figures would be desirable. Moreover, a chapter devoted to cerebral localization would add to the value of the work. On the whole, as we have said, the book filled as it is with personal experience, is a welcome addition to our knowledge, and a work which the student will find a necessary assistance in the study of the diagnosis of nervous diseases.

THE OPERATIVE TREATMENT OF TUMOR OF  
THE BRAIN.

In another column will be found the report, read before the New York Neurological Society, of two cases of cerebral tumor, in which an operation was undertaken for the removal of the new growth. We have already spoken in these columns of the now well-known operation performed by Mr. Godlee,<sup>1</sup> and the successful operation of Mr. Victor Horsley,<sup>2</sup> but we feel justified in a further consideration of the subject, because the doubtful prognosis, even of syphilitic new growths, and the almost hopeless fate of the victims of every other form of tumor of the brain, render any new attempt at relief, however desperate, of the utmost interest.

Beside the four cases referred to above, the cranial cavity has been opened six times for the removal of a suspected tumor. The first operation was performed by Dr. MacEwen,<sup>3</sup> on a suspected new growth of syphilitic nature over the Rolandic region. There was no tumor to be excised, but a false membrane was removed, the cortex incised, and some red, grumous fluid evacuated, with relief of symptoms and recovery. The first operation in this country was done by Dr. Morse, on a patient of Dr. Hirschfelder's.<sup>4</sup> The tumor, a glioma, was in the motor region of the cortex, but, owing to extensive infiltration of the growth, it could not be entirely removed, and the patient died of encephalitis on the eleventh day. Mr. Horsley has recently referred<sup>5</sup> to two other operations that he has performed for tumors in the motor region, but, although both were successful, the details have not yet appeared. Dr. Weir<sup>6</sup> has also operated before this on a patient of Dr. Amidon's, to remove a supposed sarcoma in the motor region, excising a portion of the cortex, which proved to be healthy. The patient recovered from the operation, but died in two months and a half of the

tumor, which was found, at the autopsy, on the under surface of the cerebellum, pressing on the medulla. Mr. Bennett May<sup>7</sup> reports a recent attempt to remove a tubercular tumor of the cerebellum. Contrary to his expectation, the operation was performed with comparative ease, and there was but little hemorrhage, but the child, who had been much collapsed for some days before the operation, died of shock in a few hours.

Of these ten cases, therefore, four have made a good recovery, and the fifth recovered from the operation, although the topical diagnosis was at fault. Two cases—Dr. Hammond's and Mr. May's—were not operated upon until the patient was already much exhausted, and these are the only cases in which the operation seems directly accountable for the fatal result. The other three cases died from what must be regarded as accidental and avoidable causes—inflammation or hemorrhage. On the whole, then, it would seem that, in selected cases, an operation for removal of the tumor is not only justifiable, but affords a fair chance for recovery, if done before the patient has become too much exhausted.

Unfortunately for the victims of cerebral tumor there are only certain portions of the brain that are accessible to the surgeon, and only in certain regions of these portions is our topical diagnosis reasonably certain. Tumors of the pons and basal ganglia can never be attacked by the knife, and tumors in the white matter of the centrum ovale are the most difficult to locate of tumors in any region of the brain, nor is it yet certain that, if we can locate such a growth with certainty, a deep-seated tumor can be removed. Furthermore multiple tumors can seldom be successfully located and removed. At present we can admit that only single tumors of the cortex and perhaps of the cerebellum are amenable to surgical treatment, and these are unfortunately few in number. Out of 485 cases collected by Bernhardt,<sup>8</sup> only 57 were in the cortex, and 90 in the cerebellum. In Mr. W. Hale White's<sup>9</sup> 100 autopsies at Guy's, 22 were cortical, and 29 cerebellar. Of the 100 select cases of Drs. Mills and Lloyd<sup>10</sup> nine were cerebellar, and 33 at most, were cortical. Of these, moreover, many cases of cerebellar new growths may escape the most skilful diagnostician, and there are at present only a few areas in the cortex where we can be at all sure of our localization. It is now generally admitted that in the central convolutions and their neighborhood lie the centres which preside over the movements of the body, although many observers doubt whether these centres can be mapped out as exactly as Ferrier and Horsley claim; and it is in this region in which most of the tumors operated on have been situated. Seguin has done much to establish the belief that in the cuneus is the centre for vision for one-half of each retina, and Dr. Birdsall's case is of especial interest as the first attempt to operate in this region. To these

regions we may, perhaps, add the left upper temporal convolution, the acoustic speech centre, as a region where a lesion can be definitely located. Mills and Lloyd<sup>11</sup> suggest that hereafter the tumors in the antero-frontal and postero-parietal regions may also be located with some degree of certainty. Beyond these regions our knowledge of the localization of disease in the cerebral cortex is still uncertain, and less than two-thirds of the cases of cortical tumor cited were located in the regions where an exact topical diagnosis was possible. In spite of Dr. Birdsall's conclusions, our knowledge of localization is still capable of further advance, and it may be destined to become a still better guide to the surgeon than it is at present.

Certain other factors of a purely surgical nature render the prospect for the relief of victims of cerebral tumor still less hopeful. In the first place certain forms of tumor, such as cancer and sarcoma, are as likely to recur in the brain after removal as they are in other organs. In the second place Dr. Hirschfelder's case seems to indicate that, if the tumor be infiltrated, as often happens with gliomata and sarcomata, the chances for success are materially lessened.

Mr. Horsley has called attention to certain confirmatory signs of tumor which may appear at the time of operation, and his observations have been corroborated by most of the other operators. The dura is usually forced outwards through the opening in the skull, by the great intra-cranial pressure, and the pia over the tumor is often discolored. In some cases the tumor was distinctly felt as a hard mass beneath the finger.

The unsuccessful cases have at least served to emphasize certain precautions to be observed in operating. The first point seems to be, as in all operations, that surgical interference should not be put off too long. The only cases where death seemed due to the operation were cases where the patient was already much exhausted. The need of the most rigid antiseptic precautions is also evident. In case of hæmorrhage, the vessels must be tied or twisted, or, if too deep in the cranial cavity, clamp forceps might be left in for twenty-four hours or more, as Dr. Weir suggests. Etherization should be preceded by morphine. A large opening into the skull is necessary, and, after the operation, the buttons removed by the trephine, if kept warm, moist, and aseptic, will aid in fresh bone-formation. Horsley also recommends a U-shaped flap in the dura, instead of the crucial incision.

Under these precautions it would seem that, in a certain class of cases, unfortunately too limited, the operative treatment of tumor of the brain, has a fair chance for success.

— Shall we say *prodromes* or *prodromata*? A correspondent asks what authority certain medical writers have for using the word *prodromata* as the plural of a word which others give as *prodromes*? We confess that we give it up. The Greek word is Προδρομῆς; hence the plural *prodromes* is philologically correct.

#### HEALTH OFFICERS AND PATENT DISINFECTING PROCESSES.

AN important suit in regard to rag-disinfection by patent processes has just been decided, although not finally, after a ten days' trial, in the New York Supreme Court, Part II, before Judge Ingraham and a jury. It was brought by the firm of Lockwood & McClintock against E. B. Bartlett & Co., warehouse men and disinfectors of rags, and Dr. Wm. M. Smith, Health Officer of the Port of New York, to recover \$15,000 damages; the complaint setting forth that in May, 1885, Lockwood & McClintock imported and received from Japan 2,920 bales of rags by the ship *Vigilant*, and from Leghorn, Italy, 150 bales by the bark *Battaglia*, and that they were justly entitled to the possession and control of the goods, and would have had this but for the wrongful acts and conduct of the defendants. One of the clauses of the complaint states that Dr. Smith "with intent to wrong and injure plaintiffs, wrongfully and unlawfully conspired and combined with said Bartlett & Co. to have said rags of plaintiffs condemned as unclean and infectious property, and to require said rags to be disinfected under the process used by said Bartlett & Co., so that said Bartlett & Co., would be able and entitled to charge plaintiffs therefor, and to hold and keep said rags until such charges were paid."

Another clause reads: "That in furtherance of said wrongful conspiracy and combination, said Smith, under color of his said office, but wrongfully and unlawfully, caused said rags of plaintiffs on and between June 5, 1885, and June 17, 1885, to be taken from said vessels and transferred to the place of business of said Bartlett & Co., for the pretended purpose of having the same disinfected, although said Smith and the said Bartlett & Co. knew that such rags were clean and free from any infectious matter, and were not at all dangerous to health, and did not require to be disinfected. The rags, the complaint goes on to state, were held from the consignees until October 1, 1885, and during that time "were partially subjected to a pretended process of disinfection which was worthless and ineffectual for any real purpose of disinfection, and which greatly damaged and injured the rags, but which process was fraudulently and collusively approved of by said Smith, with intent to give said Bartlett & Co., the control and monopoly of the disinfection, or pretended disinfection, of rags, so that they might be able to charge and extort from plaintiffs and others, large sums of money for such so-called disinfection."

It will thus be seen that the suit was of a double nature. It was for damages as against Bartlett for injury sustained by the forcible retention of the plaintiff's property, in pursuance of the orders of Health Officer Smith, and against both Dr. Smith and Bartlett, for conspiracy in giving and carrying out these orders. Against Bartlett the jury rendered a verdict of \$8,000 damages; but in the case of Dr. Smith they were unable to agree, although it is stated that a large

majority of them were of the opinion that the charge of conspiracy had been sustained. The case will now be taken to the General Term, and possibly to the Court of Appeals.

Whether Health Officer Smith be ultimately condemned to pay damages under this indictment or not, public confidence in his integrity and usefulness must be very seriously impaired or altogether lost. It is probable that Health Officers, Health Commissioners, and Boards of Health, will in the immediate future be more careful, than they have been in the recent past, about compromising themselves in any way, even in appearance, by any association with or employment of patent or proprietary disinfecting or other processes. It is also probable that we shall hear less of the extraordinary infectiousness of foreign rags and of the crying necessity for their invariable disinfection. The insensate clamor on this subject which filled the daily press, and even crept into some of the medical journals, two years and more ago was the most infectious element of the rag question which has thus far been brought to our notice.

#### HATS AS A CAUSE OF BALDNESS.

In the October number of the *Popular Science Monthly*, Mr. Virgil G. Eaton expatiates on the prevalence of baldness among the male members of the present generation. From careful observations made in churches and theatres of all the large cities, he finds that fully thirty per cent. of the men over thirty years of age show unmistakable signs of baldness, while nearly twenty per cent. have spots on their heads, that are not only bald but actually polished with the gloss that is supposed to belong to extreme old age alone; bald-headed men, he affirms, are most plentiful in New York and Boston. His observations have been taken among the most cultivated as well as the least refined classes; it is among the former that baldness is the most prevalent. "Of two nights," he says, "when Patti sang at the Boston Theatre, there were forty-six per cent. of bald heads on one occasion, and forty-two on another. When De Lussan appeared in 'Fra Diavolo,' I discovered thirty-eight per cent. of baldness, and at Matthew Arnold's lectures there were forty-six per cent. In fact, out of hundreds of observations, extending over several years, I have found that the higher the price of admission, and presumably the more refining the nature of the performance, the larger the per cent. of bald heads." He found in one store in New York, twelve shipping clerks, all under forty years of age, seven of whom were bald, and declares that there are more bald-headed men in Boston than there are who have black or red hair. In view of these facts he asks: "Will the coming man be bald? If not, what is the present generation doing, or what can it do to hinder such a fate?"

Among the causes of the prevailing baldness of the

present age Mr. Eaton assigns the most importance to the wearing of tightly-fitting head coverings, living in doors, and the custom of cutting the hair close. "Among savage races who live out doors and go bare-headed, baldness is unknown. To these, hair is a protection. It grows in rank profusion without care. Something is needed to protect the scalp from the sun and wind and rain, and hair grows luxuriantly; when hats and caps were invented, they took the place of the natural shield, and the hair having no longer any function to perform, fell away. The days of its usefulness in the economy of life are past, and like the tails of the monkeys and the muscles of the ears, it has become rudimentary from disease. If it is to be restored to its former glory, men must stop making 'close crops,' and must go bareheaded." He thinks that the reason why there are fewer bald-headed women than men is that women do not "shingle" their hair after the manner of the sterner sex. The recent fashion of "banging" and "frizzing" their hair, adopted by ladies of fashion, is a death-blow to their sex having good hair much longer. If it continues there will be as many bald-headed women as men.<sup>1</sup> Mr. Eaton concludes that: "the man or woman who wears a closely-fitting cap, and works in over-heated shops and stores, under the rays of gas and electric lights, cannot expect to have good hair. If they want to be 'worth scalping,' they must go out into the open air, and expose their heads so that they will feel the need of scalp locks." "Nature never makes anything for which she has no need, and when she finds that her works are of no use, she proceeds to eliminate the superfluous article."

In the May number of the *Popular Science Monthly*, Mr. W. C. Gouinlock continues the discussion of the subject. He does not think the habit of wearing warm coverings on the head, or of cropping the heads likely in itself to be of injury to the hair follicles and result in alopecia. The habit of wearing warm coverings on the head is not of recent date; the armies of Europe, for instance, no inconsiderable number of men, with heads close-cropped, have worn for a long period warmer and heavier head-gear than the modern dwellers in cities, without the same tendency to baldness. Nor are the heavy fur coverings of northern races incompatible with luxuriant hair." He does not think that close cutting of the hair has anything to do with baldness; certainly the habit of shaving the beard does not seem in races or individuals to cause disappearance of that hirsute appendage, nor does cropping the hair at the back of the head and neck, regions which are habitually cut close, favor baldness of those regions.

With regard to indoor life, this is less a factor in the production of alopecia than Mr. Eaton supposes; on the one hand, women who are the most confined indoors are the least subject to baldness, and, on the

<sup>1</sup> Reliable statistics as to the percentage of baldness among women would be interesting, but proportionately difficult to get at. We have recently become cognizant of a complete general alopecia affecting three female members of a family, a mother and two grown daughters.

other, falling of the hair is by no means infrequent in persons whose occupation keeps them most of the time in the open air.

Mr. Gouinlock believes that the common form of baldness is due entirely to the kind of hat that is worn, principally to the "high hat, and the hard-felt hat," and also "to any other head covering that constricts the bloodvessels which nourish the hair-bulbs." By close-fitting, heavy and rigid hats, the arterial blood-flow to the hair-bulbs and the return of venous blood are obstructed, and the result is an impairment of nutrition and final atrophy. "Few," he declares, "will escape the evil effects of twenty or thirty years of rigid tight-fitting hats, the destructive process being delayed only by the length and frequency of respites from this tourniquet of fashion."

If these conclusions are sound, the present generation should endeavor to undo the evil by the timely adoption of softer head coverings, whose loose rims can neither constrict the arterioles nor starve the hair-bulbs. The wearing of the unventilated beaver, which, according to Dr. B. W. Richardson,<sup>1</sup> "is a ready method of suppressing the natural growth of hair, and of causing to be retained in the hair that effete epithelial scale vulgarly called scurf," should be interdicted; and the hard-felt hat, unless it be ventilated at the top and worn loosely on the head, so as to be at the mercy of every gust of wind, must go the way of other unphysiological fashions.

As physiologists we may be permitted to doubt the adequacy of the cause assigned for our natural baldness by Mr. Gouinlock, although his view has the endorsement of so high an authority as the author of "Diseases of Modern Life."

#### MEDICAL NOTES.

— Antithermin is the latest reported antipyretic.

— Dr. Freire, of Rio de Janeiro, is in Paris demonstrating his yellow fever germ before a committee appointed by the Société de Biologie.

— Professors H. P. Bowditch, of Harvard, Mendenhall, of Terre Haute, Ind., and Cook, of Brunswick, Ga., have been elected members of the National Academy of Sciences.

— President Cleveland has appointed George M. Sternberg, M.D., Surgeon United States Army, to examine and report upon the question of inoculation against yellow fever.

— It is reported that another patient of M. Pasteur's has died in Paris. He was a Spaniard, named Ramon, who was bitten by a wolf on February 15th, and was at once sent to Paris, where he went through the "Pasteurian treatment." This is said to be the forty-fifth death from hydrophobia after treatment by Pasteur.

<sup>1</sup> Diseases of Modern Life, p. 287.

— The Marine Hospital bureau is informed that the Indians in the vicinity of Yuma, Ari., are suffering from a severe epidemic of measles, which had proved fatal in sixty cases up to the 16th of April.

— Our English confrères are chafing under the carriage-tax, which in spite of efforts to secure its reduction, remains at two guineas, in some cases amounting, it is said, to fifteen per cent. of the cost of a vehicle. To the country practitioners especially, the burden is very heavy, and prevents them from keeping a close carriage for rainy weather, and a cheaper open vehicle for fine days.

— The *London Medical Record* contains the following formula, which has been used to prepare a calming and adhesive preparation, suitable for neuralgias, or tender, inflamed, or abraded surfaces. Bits of linen or silk dipped into it answer the same purpose as the so-called "court plaster": Mastic 3ijj., balsam Peru 3j., narcotine 3j., chloroform 3vj. The three first substances must be powdered separately, and then added to the chloroform.

— The *Therapeutic Gazette* calls attention to massage as an employment especially suited to the capabilities of the blind, in whom the tactile sense is so strongly developed, and remarks that, in Japan, massage has been for a long period of time practised by blind men, who go about the streets with a flageolet, to call attention to themselves and their occupation. It adds the hint that superintendents of blind asylums will do well to consider this as a possible avenue for labor for their pupils.

— Dr. J. A. S. Grant (Bey), writing to the *Provincial Medical Journal* regarding midwives in Egypt, says that he was called to the wife of a Turkish gentleman during her first confinement, a midwife being in attendance. The pains were unusually severe, and though their violence was mitigated by chloroform, to which the native practitioners are, of course, strangers, no progress was made. The midwife proposed craniotomy, saying that the child was dead, and was provoked that the surgeon insisted on forceps, saying that she (the midwife) sometimes performed craniotomy as often as ten times in one day. It evidently was her only operative resource. The child was delivered, alive, and the midwife at once introduced her hand nonchalantly to the uterus and scraped out the placenta, that being her routine treatment.

— Some curious discoveries, according to the *Medical Press*, were recently brought before the Odontological Society of Great Britain by Mr. Charters White. He examined some dental tartar removed from the teeth belonging to dolichocephalic skulls, found in a "long" barrow near Heytesbury, the original proprietors of which were contemporaneous with the Stone Age. Decalcified and examined under the microscope, he found small, drab-colored masses, composed of altered and disintegrated epithelial scales, mixed with the contents of starch-cells. Throughout these masses were scattered grains of sand, due to the practice of

grinding corn between two gritty stones, the effect of which, in wearing down the teeth, is very apparent in the teeth themselves. In addition to the above, he was enabled to identify portions of husks of corn, hairs from the outside of the husks, spiral vessels from vegetables, husks of starch, the point of a fish's tooth, a conglomeration of oval cells, probably of fruit, barblets of feathers, portions of wool, and fragments of cartilage. The idea of deriving information as to the gastronomic propensities of our ancestors by such means is certainly remarkably ingenious. The fertile imagination of the archaeologists will doubtless suffice to build up, on this somewhat slender foundation, a legend which will be handed down to posterity, and ultimately be hallowed by its own antiquity, as well as the antiquity of the material dealt with. In future ages, remarks our contemporary, instead of scratching a Russian to find a Tartar, our descendants will scratch the tartar to find a Russian.

## BOSTON AND NEW ENGLAND.

—At the annual meeting of the Suffolk District Medical Society, held Saturday evening, April 30th, Dr. John Homans was elected President, and Dr. Geo. W. Gay, Vice-President for the ensuing year.

—The Boylston Prize of the Boylston Medical Society of Harvard University has been awarded to Mr. Charles L. Scudder for an essay on "Congenital Talipes Equino-Varus."

—Drs. J. Solis Cohen and Edward Martin, of Philadelphia, made a visit this week to the Physiological Laboratory of the Harvard Medical School to assist at some investigations, by Dr. F. H. Hooper, upon the action of the vocal cords in response to electrical stimulation, the results of which were pronounced very satisfactory.

—A bill passed the Senate of Rhode Island last week, providing that every person, firm or corporation employing minors under sixteen years of age, or women, in any manufacturing, mechanical or mercantile establishment in this State, shall provide suitable seats for the use of such minors and women so employed, and shall permit the use of such seats by such employees when they are not necessarily engaged in the active duties for which they are employed. Every person, firm or corporation who wilfully violate any of the provisions of the law shall be fined not exceeding \$20 for each offence.

## NEW YORK.

—At the "Festival of the Year," a charitable entertainment held last week, at the Metropolitan Opera House, in aid of the New York Skin and Cancer Hospital, about \$5,000 is said to have been cleared.

—A householder in Jersey City has brought suit to recover \$20,000 damages against City Health Inspector Benjamin and his assistants, for dumping night-soil against the rear fence of his premises, in consequence of disease contracted, from which, it is claimed, five children of his died within three days.

—A mother, whose two daughters have been secretly using "arsenic wafers" for their complexion, having applied to the Board of Health to inquire if the practice of selling such articles could not be stopped by the authorities, Dr. Cyrus Edson has been instructed to make an investigation of the matter.

—On the 23d of April, Dr. Charles Sedgwick Minot, of Boston, delivered an illustrated lecture on "The Evolution of the Head," before the New York Academy of Sciences; and, on the 28th, Dr. H. C. Haven, of Boston, read a paper on "Natural versus Artificial Feeding during Infancy," before the Section on Obstetrics and Diseases of Women and Children of the New York Academy of Medicine.

—A dispatch from Middletown, Orange County, dated April 26th, states that no official attempt has yet been made, or is likely to be made, to enforce the orders recently issued by the State Board of Health to the local Boards throughout the milk producing districts, instructing them to "seize and destroy" bobveal before it leaves their jurisdiction. On account of the profit derived from the forbidden traffic by the dairymen, the calf-butchers, and the railroads, public opinion tolerates it, and the local Health Boards are indifferent about the matter.

—A remarkable showing is made by the result of the physical examination of candidates from the public schools for the appointment of a cadetship at the Naval Academy, at Annapolis. The position was offered by Col. L. S. Bryce, member of Congress for the Seventh New York District, to the lads, between fourteen and eighteen years of age, in the district, who should pass the best competitive examination; and, on the 29th of April, twelve youths presented themselves at the College of the City of New York for the trial. The physical examination was made by Drs. Stuyvesant F. Morris, of New York, and Shaeffer, of the Navy, and not one of the twelve was found to answer to the qualifications as regards physique required by the Government for admission to the Academy. Of the candidates, three were rejected for defective eyesight, and four for malformation of the chest or heart troubles, while one was under the minimum stature allowed.

—One of the morning papers, in commenting on a table recently published by the *Pall Mall Gazette*, showing the death-rates of the great cities of the world, from which it appears that crowded London leads the list, while New York is bracketed with Calcutta (a city in which cholera always prevails, and has destroyed 24,000 lives in the last six years), suggests, as one cause of the large mortality in New York, the vile habits of thousands of immigrants living in filthy tenement-houses. One day last week, the Health Department is said to have seized in an Italian grocery on Mulberry Street, two thousand pounds of unwholesome food, including a large number of chickens which had died of tuberculosis. While, according to the census of 1880, the number of persons to each dwelling is 5.79 in Philadelphia, and 8.26 in Boston, in New York the number is no less than 16.37.

## Miscellany.

## DANGER ATTENDING THE USE OF PURE TEREBENE.

DR. HARVEY, of Birmingham, describes in the *British Medical Journal*, January 29, 1887, the case of a man aged fifty-six, a chronic asthmatic, who suffered from the beginning of December with severe bronchitis, with profuse muco-purulent expectoration: "On December 21st he began to take pure terebene (ten drops on sugar every four hours) with great advantage, the expectoration diminishing to nil, and the dyspnea being much relieved. After the treatment had been continued for three days, the patient was seized with intense pain in the region of the left kidney, shooting into the pelvis and down the left thigh, with blood in the urine and severe strangury. Cessation of the terebene treatment, together with the use of poultices and the administration of opium internally, resulted in speedy relief, and left little doubt that the condition was one of intense renal congestion caused by the terebene."

## OBITUARY.

## GUSTAVUS PERCIVAL PRATT, M.D.

Gustavus P. Pratt, M.D., died at Cohasset, Mass., April 29, 1887, after an illness of three months. He was born in Cohasset, February 14, 1840, and passed his boyhood and early school days there, with his grandfather, Dr. Ezekiel Pratt. He entered Phillips Exeter Academy in 1857, and graduated at the head of his class in 1860. Three years later, in 1863, he graduated at the Harvard Medical School. He was appointed almost immediately, by Governor Andrew, assistant surgeon in the Thirty-second Massachusetts Regiment. He became later brigade surgeon, and served in the Nineteenth and Twentieth regiments until the close of the war. In 1865 he went into business in Chicago, but soon returned to Cohasset, where he has since practised his profession with great success. Dr. Pratt was widely known and much esteemed in this part of the State. He leaves a widow and three children.

## E. T. CASWELL, M.D.

Edward Thompson Caswell, M.D., died at Providence, R. I., April 17, 1887, in the fifty-fourth year of his age. He was the son of the late Professor and President of Brown University. Alexis Caswell, D.D., was graduated here in 1853, received his medical education at the Jefferson Medical College, Philadelphia, taking his medical degree in 1859. He continued his medical studies in Europe, especially at Vienna and Berlin; in the latter city under the inspiring influences of Langenbeck, he turned his attention more directly to surgery, and this remained through his life the more attractive branch of his professional work. Returning from abroad in 1862, he was in the hospital service of the government at Portsmouth, Va., until a serious impairment of his health in 1864 compelled him to retire. In 1864 he opened an office in Providence and remained here, in the active practice of his profession, until his death. Successively vice-president and president of the Rhode Island Medical Society, he enjoyed the distinguished honor of being three times called upon to deliver the annual address before that body. In the years 1869-76 inclusive, he prepared the Registration Reports of his State. He was chosen one of the surgeons of the Rhode Island Hospital at its establishment, and was a consulting physician of the Providence Dispensary. He had also been president of the American Academy of Medicine, and was selected to deliver the annual address before the Alumni of Jefferson Medical College in 1879. This is the record of a busy and successful professional life, full of honors fairly earned by the faithful and enlightened service of a man of unusual qualifications for his work. Believing conscientiously in the realities and certainties of medicine, he thought no expenditure of time, health, or money too great, if he could only better prepare himself for the relief of suffering and disease. During the last year of life, when the fatal character of his illness had become a certainty to him, he did not cease from his labors, but continued to the end, bringing cheerfully to others the help that none could offer him. To all the advantages, which his home and associations had bestowed upon him, were added the grace, purity and manly strength of a Christian faith. Wherever known he was appreciated, and the community where he spent his life, mourns for the good physician.

## Correspondence.

## IN-GROWING TOE-NAIL.

[The following letter, sent in for publication, will be sufficiently clear to those who may have read the foot-note on page 324, of the April 7th number of this JOURNAL.—Ed.]

NEW YORK, April 22, 1887.

DEAR SIR, — I beg to acknowledge the excerpt from the *Boston Medical and Surgical Journal*, received through Dr. Hartley. I fancy I have not made myself clear in speaking of your operation. I only intended to convey that it had failed in my hands at times, and in the hands of others, because it had not been properly done. I have used it as is described in your last remarks some seven times with uniform success. In over a dozen other cases, success varied with the amount sliced off.

In styling it a "very little operation," I did not wish to belittle its importance, but only to allude to the fact that such minor operations were rarely to be met with in our large hospitals, and hence I *lugged* it in, so to speak, to emphasize the importance of doing it rightly.

I think, moreover, that I was among the earliest to use your operation here. Yours most truly,

K. S. WEIR, M.D.

TO DR. B. E. COTTING.

## EROSIONS OF THE CERVIX UTERI.

CARLSBAD, April 8, 1887.

MR. EDITOR, — I have read with unusual interest the paper presented by Dr. E. W. Cushing before the Suffolk District Medical Society (Section of Obstetrics and Gynecology) upon this subject, a report of which appeared in the *Boston Medical and Surgical Journal* of March 10th. Of even greater importance, perhaps, because of its advanced pathological reasoning, was the stand taken by Dr. Fitz, on the relation of erosions to cancer. In the present position of accurate scientific observation we are justified, I take it, in attributing to mal-nutrition of the body, a large percentage of these cases of local derangement of cell multiplication and tissue formation. No theory of traumatism or of irritation from noxious secretions can possibly hold, when urged as a primary cause in the case of newly-born children or of young girls. The erosion is a mere symptom of some vicious nutritious action in the cervix, which in turn may be inter-dependent with a constitutional fault of some kind. I have long believed that very many of the specific ailments of women were not so much local in their natures, as general, and that to meet rational therapeutic indications we should first address ourselves to the cause, and later attack the local symptom if demanded. The cervix possesses no potential power to originate tissue degeneration. It is simply impossible for it to inaugurate any such departure from the normal, unless there be a constitutional cause. As cervical erosions may exist without lacerations, it cannot be maintained that the latter originate the mischief. It does not seem to me probable that lacerations of the cervix have anything more than a casual relationship to erosions. Neither can I accept just yet as synonymous terms, glandular endometritis and cervical erosion. One is exaggerated cell-growth and proliferation of the body of the uterus, and the other is more like a retrograde metamorphosis. Excluding cases of cervical erosion due to direct irritating contact of a foreign body, or to the germs of noxious discharges, there yet remains a certain class of cases to be accounted for upon some other hypothesis. The normal tissue of the cervix is changed into a pathological one, because its nutrition has in some way been prejudiced. Its circulatory supply has been interfered with, either the quality or the quantity thereof. There is just a bare possibility that this defect of supply may be carried to such an extent as to produce malignant disease, though I am quite one with Dr. Fitz in failing to see how the epithelial cells are formed out of the

cylindrical ones. It has never yet been proven that a cancer of the cervix has originated from an erosion, and pathological observations certainly disprove any such train of reasoning. Clinical studies point to such a possibility—cases are even cited to prove the fact—but valuable though such clinical facts always are, they lack merit as scientific data. Dr. Fitz is entirely in accord with the most recent pathological researches in Germany. The most eminent pathologists here do not sanction yet the theory of erosions as causes of cancer, because the various steps in the process of growth, degeneration, death and new formation are not known. It rests with those who defend the theory to prove their premises. If there be a predisposition to cancer, by reason of transmitted heredity, conjoined to an erosion of the cervix, it is possible that the inherited tendency may manifest itself in the most vulnerable part. But I am quite sure that many, vastly many

more women go through life with erosions that never manifest any malignancy, than those who consult the medical man for a cancer developing out of an erosion. How is it possible for a non-malignant erosion to take on malignant action in one case and not in another? I mean what are the exact pathological processes at work? If the excitant be circulating in the blood, it might, perhaps, find its more fitting lodgment in the erosion as being the part the least adapted to resist an attack, but even then the characteristic cell should be that of the part diseased, we may never know whether such an assumption be true or otherwise, but it seems to me a tenable hypothesis, that if the woman, in whom subsequently the cancer develops, never had an erosion, she would have developed a cancer later on somewhere; so that it cannot be maintained that the local cause set up the graver sequelae.

HORATIO R. BIGELOW, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING APRIL 23, 1887.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 1,901; under five years of age 653; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fever) 271, acute lung diseases 348, consumption 283, diphtheria and croup 84, measles 48, diarrheal diseases 39, scarlet fever 22, typhoid fever 21, cerebro-spinal meningitis 16, erysipelas 11, malarial fever 11, whooping-cough 10, small-pox four. From scarlet fever New York 15, District of Columbia four, Boston two, Pittsburgh one. From typhoid fever, District of Columbia and Lawrence, four each, New York, Baltimore, Boston and Lowell, two each, Pittsburgh, Milwaukee, New Orleans, Charleston, and Holyoke one each. From cerebro-spinal meningitis, Lowell six, New York four, Somerville two, Richmond, Milwaukee, Newport and Taunton one each. From erysipelas, New York four, Boston three, Pittsburgh two, Baltimore and District of Columbia one each. From malarial fevers, New York six, Baltimore three, New Orleans two. From whooping-cough, Boston three, New York and Baltimore, two each, Richmond, District of Columbia and Lynn one each. From puerperal

fever, New York and Baltimore, two each, Pittsburgh one. From small-pox New York three, Pittsburgh one.

In the 22 cities and greater towns of Massachusetts, with a population of 1,062,033 (population of the State 1,941,463) the total death-rate for the week was 24.38 against 22.18 and 21.95 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,245,000, for the week ending April 9th, the death-rate was 20.5. Deaths reported 3,641; infants under one year of age 818; acute diseases of the respiratory organs (London) 263; measles 250, whooping-cough 117, scarlet fever 41, diarrhoea 33, diphtheria 24.

The death-rates ranged from 17.0 in Portsmouth to 32.6 in Manchester; Birmingham 17.1; Blackburn 21.9; Brighton 17.2; Huddersfield 22.6; Hull 20.1; Leeds 22.4; Liverpool 28.6; London 17.8; Newcastle-on-Tyne 21.3; Nottingham 18.6; Sheffield 21.5.

In Edinburgh 19.4; Glasgow 25.2; Dublin 30.0.

The meteorological record for the week ending April 23, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending Saturday, Apr. 23, 1887.	Barom- eter.	Thermometer.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather.			Rainfall. Duration, Inch. & Min.	Amount in Inches.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 23, 1887, TO APRIL 29, 1887.

SMITH, J. R., lieutenant colonel and surgeon. By Par. 8, S. O. 92, A. G. O., April 21, 1887. Detailed as member of board to meet in Washington, D. C., April 28, to prepare rules and regulations for the government of the Hospital Corps of the Army.

TAYLOR, MORSE K., major and surgeon. Relieved from duty at Fort Sill, I. T., May 10, 1887, to proceed home, San Antonio, Texas, preparatory to retirement. Par. 20, S. O. 92, A. G. O., April 21, 1887.

HEIZMANN, CHAS. L., major and surgeon. By Par. 8, S. O. 92, A. G. O., April 21, 1887. Detailed as member of board to meet in Washington, D. C., April 28, to prepare rules and regulations for the government of the Hospital Corps of the Army.

AINSWORTH, FRID. C., captain and assistant surgeon. By Par. 8, S. O. 92, A. G. O., April 21, 1887. Detailed as member of board to meet in Washington, D. C., April 28, to prepare rules and regulations for the government of the Hospital Corps of the Army.

CABELL, JULIAN M., first lieutenant and assistant surgeon (recently appointed). To proceed to Fort Omaha, Nebraska, and report in person to the commanding officer of that post for temporary duty. Par. 19, S. O. 92, A. G. O., April 21, 1887.

WOODRUFF, CHARLES E., first lieutenant and assistant surgeon (recently appointed). Ordered for duty at Fort Wayne, Mich. S. O. 96, A. G. O., April 26, 1887.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING APRIL 30, 1887.

ATLEE, L. W., assistant surgeon. Ordered to the Receiving Ship "Vermont."

BIDDLE, CLEMENT, passed assistant surgeon. Detached from the Naval Academy and to Marine Rendezvous, Philadelphia, Pa.

ASHBRIDGE, RICHARD, passed assistant surgeon. Ordered to the Naval Academy.

HUDSON, A., medical inspector. Ordered to the United States Steamship "Trenton."

HIBBETT, C. T., passed assistant surgeon. Ordered to the United States Steamship "Trenton."

DECKER, CORBIN J., assistant surgeon. Detached from the Receiving Ship "St. Louis," and to the United States Steamship "Trenton."

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE THREE WEEKS ENDING APRIL 30, 1887.

GOLDSBOROUGH, C. B., surgeon. Leave of absence extended thirty days, on account of sickness. April 20, 1887.

DEVAN, S. C., passed assistant surgeon. Granted leave of absence for thirty days, to take effect when relieved. April 12, 1887.

BRATTON, W. D., assistant surgeon. To proceed to Port Townsend, W. T., and assume temporary charge of the service. April 21, 1887.

#### SOCIETY NOTICES.

GYNECOLOGICAL SOCIETY OF BOSTON.—The next meeting of the Society will be held at the Medical Library Room, No. 19 Boylston Place, on Thursday, May 12, at 4 o'clock, P. M. Reader: Dr. H. J. Harriman, "The Relation of Improper Allmentation to the Ill Health of Women."

H. J. HARRIMAN, M.D., Secretary.

NORFOLK DISTRICT MEDICAL SOCIETY.—The annual meeting will be held at Rockland Hall, No. 2343 Washington Street, Roxbury, Tuesday, May 10, at 2 P. M. The Board of Censors will meet at 1 P. M. Order of business: 1. Reading of Records. 2. Report of Committees. 3. Election of Officers. 4. Report of Treasurer. 5. Incidental Business. 6. Communications: (a) "The Third Stage of Labor," E. G. Morse, M.D. (b) "A Case of Probable Intussusception with Recovery," E. F. Dunbar, M.D. 7. Introduction of newly-elected Officers.

S. ALLEN PUTTER, M.D., Secretary.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT.—THE SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE will meet at 19 Boylston Place, on Wednesday, May 11th, at 7.45 o'clock. Papers: Dr. F. W. Stuart, "Can Cirrhosis follow Trauma? a Case of Medico-Legal Interest." Dr. F. I. Knight will report "A Case suggesting some Considerations in regard to the Contagiousness of Tubercular Disease of the Lungs." Dr. John S. Billings, of Washington, is expected to be present, and to take part in the discussion.

ALBERT N. BLODGETT, M.D., Secretary.

F. I. KNIGHT, M.D., Chairman.

#### BOSTON CITY HOSPITAL EXAMINATIONS.

The semi-annual examination of candidates for the position of externe at the Boston City Hospital, will be held Wednesday and Thursday afternoons, May 11th and 12th, at the Hospital, at 4 P. M. E. H. BRADFORD, Secretary.

160 Boylston St., at Home 1-3 P. M.

#### DEATH.

Died in Cohasset, Mass., April 29, 1887, Gustavus Percival Pratt, M.D., M.M.S.S., aged forty-seven years.

#### BOOKS AND PAMPHLETS RECEIVED.

The Rhus Glabrum. A Remedy for Stomatitis. By Hiram Corson, of Conshohocken, Pa. 1887. (Reprint.)

Will Contests. By Walter E. Rex, Esq., formerly Register of Wills for the City and County of Philadelphia. 1887.

Cocaine in General Surgery. By John B. Wheeler, M.D., Instructor in Surgery, University of Vermont. Montpelier, Vt., 1887.

Report of the Commission appointed by the Governor of Minnesota to Locate and Prepare Plans for a Third Hospital for the Insane. St. Paul, 1887.

A Successful Case of Partial Excision of the Larynx on account of Intra-Laryngeal Epithelioma. By Lennox Browne, F.R.C.S. Ed. (Reprint.)

Some Considerations concerning Cancer of the Uterus, especially its Palliative Treatment in its Later Stages. By Andrew F. Currier, M.D. 1887. (Reprint.)

A CASE OF DIFFUSED GANGRENE OF THE RIGHT LUNG, FOLLOWING PYORRHEA ALVEOLARIS.<sup>1</sup>

BY C. ELLERY STEDMAN, M.D., OF DORCHESTER, MASS.

I WAS asked by the husband of a patient to meet her at the dentist's, where she was to have all her teeth extracted, and administer the ether. The operation was done by Dr. F. F. Gage, with great rapidity and skill, on the 8th of October, 1885. During anesthesia she collapsed, and for five minutes seemed moribund. The anæsthetic having been suspended, the blood cleared from the mouth, a subcutaneous injection of a drachm of brandy given, the operation was completed. She rallied in half an hour from the ether, and was driven home in a close carriage.

This patient was thirty-one years old, and had been married four years. Her father died of pneumonia; her mother, now living, lost her teeth several years ago, as did the patient's brother. A paternal grandfather died of cancer. Aunts and uncles are presumed to be healthy. She had never been a robust woman, and had been under treatment for various ailments since childhood. She was specially subject to chills, which were called malarial, but which were probably due to the condition of her gums, which had been diseased for eight years or more. She always suffered abnormally from the usual cold of winter, and then experienced difficulty in respiration. The summer before the teeth were removed she had amenorrhœa and other symptoms of pregnancy, which condition an examination proved not to exist, and she improved greatly on spending the summer at the shore.

On the day before the operation she had one of her chills, but it did not confine her to her chamber. The teeth having been extracted on the 8th, a slight cough and fever developed on the 9th. The gums healed in quickly, and such fetor was noticed as would be expected from the suppurating surface, and was relieved by a myrrh lotion. For a day or two she seemed to be recovering from the operation, as, on the 10th, the temperature was 98°; but, on the 13th of October, pneumonia was suspected, because the temperature shot up to 103.4° (the highest point it reached). The pulse was as high as 120 on one day only. There followed cough; scanty expectoration of not very viscid sputa, at rare intervals, rusty. During the first few days there was some delirium. The physical signs, at first, were negative; to the last, the front of the chest was clear, and the heart-sounds normal. Evidences of consolidation were heard in the middle of the right back, and extended downwards and upwards, till little or no free respiration could be heard. Once or twice the left back was suspected, but the sounds were transient, and proved to be transmitted. There was little or no pain. The sputa, never abundant, grew more and more fetid. This was at first ascribed to the condition of the gums, but these healed with remarkable speed, and probably, by the third day, presented no suppurating surface. After one or two remissions, which, for a day or two at a time, gave hope, she died, in full consciousness, at midnight of the 31st of October, on the nineteenth day of the disease. Dr. Whittier saw her twice in consultation. The chart is appended. The autopsy was made by Dr. Fitz on the 2d of November, and he has kindly sent me his notes.

<sup>1</sup> Read before the Norfolk District Medical Society.

AUTOPSY, THIRTY-FOUR HOURS AFTER DEATH.

Rigor mortis present. Frame small; well-formed; abundant subcutaneous fat-tissue. Head not opened. Nothing abnormal found on examination of heart and left lung. Right lung adherent throughout by fresh adhesions, except at the base, in front and behind, where circumscribed cavities were found. In each were about four ounces of foul-smelling, opaque, greenish-yellow fluid; these cavities communicated with the interior of the lung through sloughing tissue. The right upper lobe showed nothing abnormal; the lower lobe moderately retracted. A few cavities as large as English walnuts were present, with sloughing walls and offensive contents. In several instances, the beginning cavity-formation followed the course of the bronchial distribution, dilated bronchi being thus suggested. There was but little solidification of the lung-tissue between the gangrenous centres. The spleen was slightly enlarged and soft; the kidneys and liver presented the appearance of parenchymatous degeneration. Bladder not abnormal. External examination of stomach and intestines showed nothing abnormal. The sigmoid flexure formed an unusually large loop: adherent to its mesentery was the left ovary, apparently more than two inches from the uterus. The latter organ, of the average size, was malformed, consisting of but one horn—the right. The left horn was represented by a thin, flat, red band, within the broad ligament, and to which was attached a fibromyoma as large as a plum. About an inch and a half from the attachment of the band to the uterine wall, the round ligament was given off. The left Fallopian tube was not recognizable. The left ovary normal in appearance. Diagnosis: Gangrenous broncho-pneumonia; putrid empyema; malformation of uterus (one horn developed, the other solid and rudimentary, with a fibro-myoma).

In the chart, you will notice the low run of the pulse, temperature, and respiration; the course of the disease—nineteen days—so different from the record of a frank case of pneumonia. The remissions of temperature on the second and thirteenth days are worthy of note. You will also see how the temperature fell after moderate doses of antipyrine, which was always given with brandy. The treatment was liberally restorative: she took enough milk, champagne, and other food and stimulants readily, and retained them all. The slight delirium spoken of above did not cloud her mind, and, as has been said, she died aware of all

that was going on around her, and was so mistress of herself, that she expressed a desire to make her will; and, after it was drawn up, she signed it very shortly before her death.

The disease of the gums from which the patient suffered is called, by the dentists, pyorrhoæa alveolaris, and by some Riggs's disease. It appears to begin with a calculeous deposit around the necks of the teeth, and is said to be not uncommonly found in the mouths of very young patients—say, even those of two years. The deposit can be seen, and its presence is also manifested by a more or less distinct line of inflammation about the necks of the teeth. The gums become more or less congested, and cover the deposit, while the mischief proceeds in secret, the gums bleeding easily. If not removed, this deposit will go on hardening, clinging more tenaciously to the necks of the teeth, and extending its boundaries . . . the soft tissues shrink or recede . . . the disease attacks the hard tissues, and they yield more or less rapidly. The thin edges of the alveolar process are the parts now involved, and, from the breaking down of their structure, we have an easily perceptible discharge of pus. It is more intractable when hereditary.<sup>2</sup> The remedy for this formidable disease is the early removal of the deposit, or extraction of the teeth when it is advanced.

Gangrene of the lung is a rare disease. The case under consideration is the first in my own practice, and I recall only one or two in my hospital experience. In 1866, Dr. Austin Flint had seen fifteen cases, and cites the record of 1,069 autopsies by Lauthna, of Vienna, who found among them only five instances. Fischell, of Prague, in 3,437 necropsies, noted 75 cases of pulmonary gangrene. Ten years' post-mortem records in St. George's Hospital afford nineteen cases only. The fatality of the disease is large; the patients generally die before the slough can be cast off, its presence setting up septicaemia or secondary pneumonia. Dr. Coupland<sup>3</sup> has collected some cases, principally reported with a view to operative procedures, in an able and interesting paper in the *British Medical Journal* of the 5th of September, 1885. The cases in the autopsy-book of the Middlesex Hospital, from 1875 to 1885, numbered thirty-eight. In a paper in the *Boston Medical and Surgical Journal*, 26th of October, 1876, Dr. Thomas W. Huntington reports thirty-two cases in the Massachusetts General Hospital, from 1857 to 1875. Of these, seven were discharged well, six much relieved, three temporarily relieved, five not relieved, eleven died. In summing up, Dr. Huntington finds that 73.3 per cent. of cases uncomplicated recovered, while complicated cases showed 80 per cent. of deaths.

The most frequent cause has been thought to be acute pneumonia, ending in gangrene, but I think that if a full history of each case could be procured, most of the patients would be found to have been exposed to some septic influence. Again, drunkards are peculiarly liable to this form of inflammation of the lung. Blocking of the pulmonary vessels does not necessarily lead to gangrene, but rather to that form of necrosis which is known as hæmorrhagic infarction, unless the occluding matter be of septic character. The inhalation of putrescent matter is a cause, such as retained bronchial secretions, or morbid extra pulmonary products, or foreign matter from without. Malignant ulceration in the mouth is stated as a cause in

more than one case. It often happens that after the first urgent symptoms of impaction had ceased, the patient lies in a condition of comparative comfort. Dr. Sydney Coupland cites illustrations of all these instances. Octavius Sturges adds cancer, carious vertebrae, and aneurismal tumor. Dr. Coupland also says the relationship between gangrene of the lung and acute lobar pneumonia has hardly yet received satisfactory explanation. Laennec considered that the surrounding inflammatory change was purely secondary, and there is, no doubt, much truth in this view of the case. But yet there remains a fair proportion where there seems no room for questioning the fact that acute pneumonia has ended in gangrene. In the rest, the limitation of the pneumonic areas, the distribution of the gangrenous foci, point to the hepatization being secondary to the gangrene. At the same time, no adequate cause for the gangrene can be assigned.

Octavius Sturges<sup>4</sup> is strong in statement that true pneumonia never ends in gangrene. He writes that the cases which are obnoxious to gangrene are precisely those which are least liable to true pneumonia; are those, it almost might be said, where the state of the blood renders such an occurrence impossible. We have the testimony of authors that the liability to gangrene varies inversely with the liability to pneumonia. Gangrene of the lung is more rare in enteric fever than in typhus. Pneumonia is more rare with typhus than with enteric fever. . . . Dr. Stokes, who is little prone to accept doctrines on the mere authority of others, insists on the close connection between gangrene and what he elsewhere describes as "typhoid pneumonia." . . . A separate form is met in children. . . . The extravasation of blood (hæmoptysis) may terminate in a gangrenous cavity, the access of air to a lot determining its putrefaction, and, eventually, that of the surrounding tissues. M. Grisolle, who concurs with Frank, Laennec, and Andral in regarding this event of pneumonia as very rare, investigated the history of seventy reported cases of pulmonary gangrene. He relates that he could hardly find five out of the seventy which could, in strictness, be regarded as examples of pneumonia so terminating. Dr. Thorowgood gave Dr. Sturges particulars of a case, in which the characteristic and overpowering fetor of pulmonary gangrene arose in a pneumonia of no great severity, and which ultimately recovered, under his care, at the West London Hospital.

Gangrene of the lung occurs in two forms: the diffused and the circumscribed.<sup>5</sup> In the former, the gangrene extends over a considerable space, sometimes involving the greater part of a lobe. This is the graver form, and almost of necessity proves fatal. The circumscribed form is that which usually occurs. In this kind, the gangrene is confined to a space limited in size from that of a bean to a hen's egg, the limits being sharply defined. Even when circumscribed, it is an extremely grave affection, but recovery takes place in a certain proportion of cases. The chances of recovery are differently estimated by different writers, which may, perhaps, be accounted for by supposing that the diagnosis of gangrene is not infrequently based on insufficient grounds. Fetid sputa are not restricted to this disease. Among the conditions simulating gangrene of the lung, are the sloughing of pulmonary tissues in tubercular cavities, a superficial slough of a

portion of the bronchial mucous membrane, and the retention of old secretions in cases of bronchiectasis.

We thus have the history of a patient never very strong, who, after long disease of the gums, under which pus was secreted, fell a victim to pulmonary gangrene. As malignant ulcerations of the mouth are a cause of this disease, so the condition of the alveolar mucous membrane placed her in a favorable state for the onset of the fatal illness. Gangrene of the lower lobe of the right lung set in, and, to the septic condition of the mouth, may be added, as a possible cause, entrance of blood into the bronchi during the operation of extraction, particularly during the collapse. Perhaps the collapse, too, may have been caused by the plugging of a bronchial tube with blood flowing from the gums into the trachea during anesthesia. The decomposition of such clots, even when caused by hæmoptysis, has been noted above as originating this form of disease. Careful search was made in the autopsy for the signs of any such plugging, but none could be found. I am more inclined to place the cause of death with the long disease of the gums, favoring the fatal illness.

#### CASE OF ATTEMPTED SUICIDE FROM THE INGESTION OF THIRTY-SIX GRAINS OF MORPHIA, WHICH REMAINED IN THE STOMACH FIVE HOURS. RECOVERY.

IN THE PRACTICE OF DR. L. E. LEMEN, DENVER, COL.

REPORTED BY SAMUEL A. FISK, A.M., M.D., DENVER, COL.

WILLIAM P., aged thirty-eight years, a German, six feet in height, about two hundred pounds in weight and of powerful build, becoming tired of life attempted suicide by taking a large dose of the sulphate of morphia. At ten o'clock on the night of March 6, 1887, in the presence of a woman with whom he had had a disagreement, he opened a one-eighth of an ounce bottle of Powers & Weightman's sulphate of morphia, which he had bought for the purpose of committing suicide, poured out a large quantity on to the palm of his hand, and ate it down. The drug remaining in the bottle proved to weigh twenty-four grains, making the amount that he took in the neighborhood of thirty-six grains. After taking the drug he remained in the woman's room some ten or fifteen minutes, when, under the apprehension that a physician was being called, he ran down stairs, jumped into a hack, and was driven about a mile and a half to his home. On the way he opened a small vial of the spirits of chloroform, that he had with him, and drank a fluid drachm. When he reached his house and got out of the hack, the driver thought he was drunk. P— afterwards stated that the last thing that he remembered was his getting into bed on reaching home. He drank freely of water and, on the arrival of the woman with whom he had quarrelled, he was given a couple of glasses of milk, and a physician was summoned.

Half-past twelve, March 7th. Two and one-half hours after the ingestion of the drug, Dr. L. E. Lemen, who was called and who took charge of the case, arrived. Respirations were six per minute; pulse sixty-eight. Pupils pin-hole. Patient cyanotic. Ten grains of tartar emetic were placed upon the tongue and an attempt was made to wash it down, but the reflex effort of swallowing could not be excited. The at-

tempt and the dose were repeated, with a like effect, in about twenty minutes. Twenty minims of the fluid extract of belladonna were given hypodermically at 12.30, A.M., and the dose was repeated at 12.45, and again at 1.15.

Quarter-past one, A.M. Three and one-quarter hours after ingestion of the drug, I arrived with my battery. Found the respirations three per minute; pulse eighty-four. Pupils moderately dilated, due, no doubt, to the belladonna. We immediately applied the galvanic current from eighteen cells of a McIntosh Battery, the negative pole being placed over the right superior, carotid triangle, the positive over the præcordium, and the current interrupted very slowly. Galvanism and the belladonna brought up the respirations, both in depth and number.

Two, A.M. Four hours after ingestion. One-sixth grain of apomorphia was given hypodermically and an attempt to wash out the stomach with a soft-rubber tube was made, which failed, as the tube was not stiff enough. The hypodermic injection of apomorphia, one-sixth grain dose, was repeated in about twenty minutes after the first injection and followed in twenty minutes more by a third injection, making one-half grain in all of the drug that was given hypodermically, but it was of no avail.

Three, A.M. Five hours after ingestion. Galvanism having been kept up pretty constantly, an œsophageal tube was introduced into the stomach and it was thoroughly emptied and washed. The citrate of caffeine, grains fifteen, in solution, was then administered by the tube and the tube withdrawn. At this point the respirations ceased, the heart stopped beating and could not be heard over the præcordial region. The face and surface of the body became pallid, and we were afraid that life had flown.

Galvanism from eighteen cells was applied as before, and after three or four minutes a shallow inspiration occurred, and a second, and a third. Electricity was continued, the expirations were increased by compressing the chest, the heart started beating again, the respirations were restored, and the patient broke out into a profuse cold sweat.

Four, A.M. Six hours after ingestion. The stomach tube was introduced a second time and fifteen grains more of caffeine administered. On withdrawing the tube the pulse and respirations stopped as before, and were reproduced by galvanism as described. The respirations soon became Cheyne-Stokes in character, four or five series to the minute, and from that time for several hours but little was done except to stimulate the inspirations with a weak galvanic current whenever they seemed to flag.

Nine, A.M. Eleven hours after ingestion. Respirations eighteen per minute and fairly regular. Pulse one hundred. Patient unconscious.

Eleven, A.M. Thirteen hours after ingestion. Gave strong coffee, by spoonfuls between the cheek and the teeth, some of which would be drawn into the trachea and produce a violent coughing and the patient would thus become partially aroused, but dropped off instantly into slumber again. Could arouse him and make him cross for an instant or two, by pulling his beard. Slapping the face with a wet towel produced contractions of the orbicularis palpebrarum and corrugator supercillii. The citrate of caffeine in six-grain doses was administered every two hours for four or five doses, and we kept pouring down black coffee by

spoonfuls and by arousing patient enough for him to drink a little.

Three, P.M. Seventeen hours after ingestion. Vomited a little. Could be aroused sufficiently to be made to walk, supported by a man on either side. Pulse one hundred and twenty and thready. Respirations normal. Very drowsy, but could be kept from going into a deep sleep by talking to him. Skin bathed in perspiration.

Six, P.M. Twenty hours after ingestion. Sufficiently conscious to answer questions intelligently. Voice very husky, and he complained of his throat's hurting him. That night he vomited profusely and repeatedly.

The subsequent history was marked by great physical prostration; by a sore throat, on which some sloughing patches occurred; and by a cough, which with the ulceration in the pharynx lasted about ten days. At the end of that time he was able to get up and be around, and to-day he is a well man.

The interest of this case attaches to the fact that so large a dose of morphine could remain for five hours in the stomach of a perfectly healthy man, subject to the rapid absorption that would come from the stomach being empty, and yet that recovery should take place.

That the amount taken was about thirty-six grains, we feel sure, because he bought a fresh one-eighth ounce bottle, opened it in the presence of the woman, poured out a large quantity of the drug on to the palm of his hand, and ate it down. The remnant left in the bottle weighed just twenty-four grains.

That the drug taken remained in his stomach five hours we are equally positive, because from the time of his taking the drug, until his stomach was washed out, five hours afterwards, he was constantly in the presence of some person, and there is no history of his having vomited or purged in that time.

It is unfortunate that the washings of the stomach were not saved, so as to have determined accurately the amount of the drug that was not absorbed, and so, to have learned the real point of interest, the quantity of the drug that was absorbed. But so desperate did the case look, at the time, that it did not occur to us that there would be any need of reporting it, save to the Health Office, and the washings were thrown away.

We offer no excuse for the extreme measures taken in handling the case, except the urgency of the symptoms and the final recovery of the patient.

We are conscious that the stomach should have been washed out earlier than it was, but the delay was in a large degree unavoidable. The case has taught us, however, the necessity of emptying and washing the stomach even in apparently hopeless cases.

In turning to the books on my shelves, I find a case, cited by Reese in his "Manual on Toxicology," where a druggist swallowed *seventy-five* grains of sulphate of morphia. No marked symptoms appeared for an hour and a half, when he began to feel sleepy and had a staggering gait, soon after this emetics were given; causing free emesis. Despite the fact that the amount of the drug ingested was twice that taken in the case here reported, the absorption was evidently not as great—due to the fact that it was retained only an hour and a half, as against the five hours in this case.

Ziemssen's Cyclopædia (Vol. xvii), states that Bonjean witnessed a recovery after twenty-five grains of the acetate of morphia were taken: and Wood, (Ther-

apeutics, etc., p. 216), says the maximum doses from which recovery has taken place *without* emesis are fifty-five grains of the solid opium, equivalent to nearly seven grains of morphia.

## A CASE OF PREGNANCY IN A UTERUS BILOCULARIS.<sup>1</sup>

BY G. S. STEBBINS, M.D., SPRINGFIELD, MASS.

MRS. A., thirty-six years of age, had been married ten years, and never been pregnant. She had always been an intense sufferer from dysmenorrhœa, having been obliged at every menstrual period to remain in bed from three to four days, and have hypodermic injections of morphia administered, or resort to frequent use of opium suppositories per rectum. I am confident that her sufferings during her periods, taken altogether, were greater than those attendant upon ordinary cases of labor. Pregnancy had been suggested to the patient as the most hopeful remedy, but however gladly she would have availed herself of the relief that such a condition might have afforded, it was quite evident that there was some physical impossibility that stood in the way. Examination per vaginam revealed a very narrow, contracted os, which well-nigh amounted to stenosis of the cervical canal, and which, I assured the patient, was the cause of her sufferings, and her non-pregnant state. As the patient was desirous of obtaining relief at all hazards, I suggested dilatation of the cervix, which operation she finally assented to. I dilated pretty thoroughly with the steel dilator, and in a few months afterward she became pregnant as was supposed, but the question of pregnancy was rendered a doubtful one, by the subsequent history of the case for four or five months.

About six or eight weeks after her last period, she began to experience intense pain in the right ovarian region, the abdominal walls at the same time becoming so sensitive, that she could not turn in bed, nor hardly tolerate the weight of the bed-clothes. These symptoms continued very severe, and were unendurable unless she was continually under the influence of opiates. Soon there began to be visible enlargement in the right iliac region, the modulated, uneven outline of what appeared to be a tumor being readily mapped out by gentle pressure, the growth seemingly extended just above Poupart's ligament, the upper border rising up inside the ilium to its anterior superior angle. At the termination of the fifth month, there was no enlargement in the median line perceptible to the eye, nor to be distinguished by pressure on the abdominal walls; neither did examination per vaginam reveal anything except an elongated, oedematous condition of the posterior lip of the os, which felt like a bladder of water. A sympathetic condition, manifested according to some authors, in cases of tubal foetation.

The uterine cavity was still apparently empty, as far as the vaginal examination shed any light upon the case. The following question now arose: was she really pregnant? If so, was it a case of extra- or intra-uterine pregnancy? Had she a tumor? If so, was it ovarian; or was it some growth involving the broad ligament? If either of the latter, was the growth benign or malignant?

At this juncture, at my suggestion, a veteran in

<sup>1</sup> Read before the Springfield Society for Medical Improvement.

obstetrical warfare was called in council to help solve the problem. After a thorough examination of the case, he stated, with convincing assurance, that he could tell what it *was not*, but was unable, by any and all means, even by method of exclusion, to arrive at a positive, or even anything like a satisfactory diagnosis.

So far as we could arrive at conclusions, we agreed that the uterine cavity proper, was empty. This fact was quite apparent. We further agreed that if it was a case of tubal foetation, rupture should and doubtless would have taken place long before. Motion should also have been noted at this date, but had not been discovered. We finally agreed that it only remained to await the progress of events, and to treat the symptoms as they should become urgent.

From this time forward, for at least two months, until the completion of the seventh month, the abdominal enlargement continued to the right of the median line, but gradually extending toward it, until early in the eighth month, when the fundus of the uterus appeared to be reaching nearly its normal position, and the abdominal development presenting a uniform appearance. At the beginning of the ninth month, examination per vaginam disclosed the fact of head-presentation.

During the whole term of gestation, pain, and great abdominal tenderness continued, the patient having been obliged to remain in bed continually for the last seven months, unable to turn or lie on either side. Once she was assisted out of bed and tried to walk around it, but after taking a few steps sank to the floor. During the last two months, syncope, lasting from one to three hours, became an annoying, not to say an alarming symptom. At these times she could hardly speak above a whisper, or raise her hand, and required constant fanning in order to breathe.

With such a history antedating labor, of course I anticipated that event with no little anxiety, and not a few misgivings. The patient's female friends, with that wonderful and mysterious lack of sense so characteristic of women on kindred occasions, expressed grave doubts as to the final results of the case, and assured her that she need not hope to have a living child: which prophecies, I am happy to say, were not fulfilled.

When labor began, as might have been expected, the pains were irregular, weak, and the first stage of labor slow and tedious. Labor, however, progressed slowly, until the head began to press slightly upon the soft parts, when all progress ceased, and the patient appeared much exhausted, a condition to be expected, considering the case. I then applied the forceps, and delivered in fifteen or twenty minutes, Dr. Baggs having etherized the patient. While I was attending to other matters, Dr. Baggs kept up firm pressure upon the uterus, which contracted fairly well, but later, our united efforts of traction upon the cord and expression, failed to dislodge the placenta, after which, I introduced my hand into the uterus, where I not only found a firmly adherent placenta, but a solution of all of the unusual phenomena attending her whole period of gestation.

I could distinctly feel a strong membranous septum, which divided the uterus vertically, into two compartments. One portion of the placenta extended high up on one side the partition, and the other portion occupied a corresponding position on the opposite side of the septum, proving the case to be one of a uterus bi-

locularis, so well-described in Courty's work on "Diseases of the Uterus, Fallopian tubes, etc.," and in Getchell's "Obstetrics."

Pregnancy having taken place in the right cavity of the uterus, it might have been the cause of the lateral flexion of the organ low down in the iliac region, where the first period of development was so manifest, and troublesome; but it is more than probable that the uterus was laterally flexed *prior to pregnancy*, the latter being the diagnosis of Professor Breisky, of Prague, in a case coming under his observations during the past year, presenting a similar history, and the same general array of symptoms.

Had we used a uterine sound as a means of diagnosis in the early months of pregnancy, it would most likely have been introduced into the left cavity of the uterus, which would have been found, and declared to be empty.

The great pain and tenderness during the first seven months of pregnancy, I account for in this way: the growing foetus gradually raised the laterally inclined uterus toward the median line and normal position, at the same time crowding the septum to one side, until finally it worked its way down into the lower portion of the uterine cavity, by the yielding of the lower portion of the septum. Before the placenta was removed, the contracted uterus appeared larger than is usual, and its shape as felt through the abdominal walls, was peculiar. Instead of feeling like a globular body, it was broad, triangular in shape, and in the median line a well-defined depression could be distinctly felt on pressure. Getchell, in his work on obstetrics, in describing such a case says: the breadth of the uterus is greater, especially at the fundus, where a depression in the median line indicates the situation internally of a vertical septum, which more or less completely divides the uterine cavity into two compartments. He adds: "Great difficulty and danger may arise during the progress of gestation."

He cites what he calls a remarkable case of Rokitsansky's, the pathological specimen of which is now to be seen in the Vienna Museum. In this case death took place from rupture of the septum in the third month, the termination as he says, being what one would expect from development of the ovum in the Fallopian tube.

Rokitsansky, in speaking of the effects of such uterine anomalies on parturition, says: "the axis of expulsion may be so directed as to place the forces at an obvious disadvantage, but when complete intra-uterine development has taken place, there will not likely be any impediment during delivery, which may not be overcome by the application of ordinary principles."

Having given the history of the case antedating and during labor, together with a description of the attendant uterine anomalies, I will speak of the subsequent history. Considering the long-continued pain and tenderness about the abdomen, I confidently expected puerperal peritonitis, and was not in the least disappointed. The whole abdomen soon became exquisitely sensitive, painful and tympanitic. The temperature ranged from 102° to 104°, for about ten or twelve days, and the pain was so severe as to require the free use of hypodermic injections of morphia, and suppositories of opium and belladonna per rectum. Quinine and turpentine were given internally, the former to reduce temperature and for its tonic effect; the latter to relieve the discomfort due to the tympanitic condi-

tion. The bowels were occasionally relieved by injections and saline laxatives. The tympanites was so distressing at times, that it was best relieved by the introduction of a tube high up in the rectum, through which the gas freely escaped. The abdomen was kept covered with poultices of flaxseed and mustard, and later, was painted twice daily with tincture of iodine. I have said that the patient remained in bed seven months prior to her confinement, and I believe it was just three months after labor before she could walk a step. She first began to walk the 7th of March, and can now, April 1st, get about the house nicely and carry her child in her arms. The child weighed eight and one-half pounds at birth.

The patient, not nursing her child, has menstruated once since her confinement, and was rejoiced to know that the function was comparatively painless. I am now confident that the pregnancy, though a severe remedy, will result in a greater measure of health and comfort for the remainder of her menstrual days.

#### REPORT ON DERMATOLOGY.

BY G. H. TILDEN, M.D.,

Physician to the Department for Diseases of the Skin, Boston City Hospital; Instructor in the Boston Polyclinic.

##### FIBROMA MOLUSCUM.

Drs. HÜRTLE and C. Nauwerck<sup>1</sup> report five cases of elephantiasis (*sic*), the examination of which confirms the statement of Von Recklinghausen, that the development of fibroma moluscum has its starting point in the cutaneous nerve-sheaths.<sup>2</sup> In three of these cases, the condition of things was found to be in all respects the same as that described by Von Recklinghausen, and, in one instance, the very earliest stage in the evolution of multiple neuro-fibromata could be demonstrated. This consisted in a thickening of the endoneurium, and later, also of the perineurium of the cutaneous nerves, which resulted in induration, spindle-formed swelling, and nodulated thickening of the affected nerve-fibres. Further developments of this nodulated condition of the cutaneous nerves implicated the adjacent hair-follicles, sweat-glands, and blood-vessels in the pathological process, several of the latter being almost obliterated by cell proliferation in their intima.

The newly-formed connective tissue, of which the tumors were composed, contained numerous nuclei, and was easily to be distinguished from the more coarsely-meshed cutaneous connective tissue. Even in the largest tumors, it was always possible to detect the string of cells, representing the nerve-fibre which had been primarily affected, and from which originated the new formation of connective tissue composing the tumors.

In a fourth case, which presented, on the thighs, a condition of diffused fibrous thickening, resembling in appearance ordinary elephantiasis, the same atrophied residua of nerve-fibres could be made out in the midst of the newly-formed and abundant cellular connective tissue, which had involved and imprisoned the cutaneous glands, hair-follicles, and the subcutaneous fat. In regions of the body where the pathological process was less advanced, the thickening of the skin was almost entirely caused by the formation under it of these

neuro-fibromata. The fifth case represented an instance of ordinary and acquired elephantiasis lymphangiectica, which, in contra-distinction to the other four cases of so-called neurotic elephantiasis—more properly speaking, multiple neuro-fibromata—presented no affection of the cutaneous nerve-fibres, but, on the contrary, enormous dilatation of the lymph and blood-vessels of the skin and subcutaneous connective tissue.

##### MYCOSIS FONGOIDE.<sup>3</sup>

At the meeting of German naturalists and physicians held in Berlin during September, 1886, both Geber and Köbner presented communications upon this disease. The former mentioned two examples of the malady which had come under his observation, since the appearance of his first publication on the subject in 1878.<sup>4</sup> One of these cases occurred in a man of sixty years of age, the clinical appearances being those of chronic eczema, attended with very great and universal pruritus. Several of the eczematous patches became somewhat elevated above the level of the surrounding skin, and, deprived of epidermis, presented a mammillated appearance. There were not developed any of the tumors peculiar to mycosis fungoide, and no mention is made of any enlargement of the lymphatic glands. The diagnosis was a purely clinical one, the patient being unwilling to have any portion of the cutaneous lesions excised for purposes of microscopical examination.

The fact of spontaneous recovery, which occurred in this instance after the disease had lasted eighteen months, is a remarkable one; for, of all the cases reported since Alibert's first description of the malady, in 1835, some forty in number, in only two other instances have the patients been known to recover: one mentioned, by Bazin, as having been restored to health after an attack of migrating erysipelas; and the other, reported by Köbner, as recovering after treatment with arsenic. The second case occurred in a woman, sixty-three years of age, and the disease had already existed for fifteen years, when she was first seen by Geber, at which time the clinical appearances were those of a combination of psoriasis and chronic eczema. The patient remained in the hospital for seven months, and was then discharged in a miserable condition, having received no benefit from any kind of treatment. Several of the cutaneous nodules were excised, and histological examination showed, in the papillary layer of the skin, the reticulated structure, containing round cells, and characteristic of mycosis fungoide. Inoculation of animals and men with blood and scales from the cutaneous lesions produced no effect. Inoculation of gelatine with the viscid secretion from these lesions resulted in the formation of colonies of what proved to be merely staphylococcus aureus. Sections of pathological tissue, stained by Gram's method, and examined with oil immersion and Abbe's illumination, showed the presence not only in the bloodvessels, but also outside of them, between the connective tissue fibres, of micrococci, diplococci, and streptococci. It could not be made out, however, that these microorganisms caused any thrombosis of the bloodvessels, as has been stated to be the case by Rindfleisch. Geber considers the presence of these microorganisms, which varied very much in size and distribution, as merely accidental and having no special connection with the disease.

<sup>4</sup> Deutsches Archiv. für Klin. Med., Band xxi., Heft 3 und 3, 1878.

Köbner recognizes two varieties of mycosis fungoides, one presenting more isolated and pedunculated tumors than the other, which is characterized by a wider dissemination of the cutaneous lesions. He mentioned the fact that, in one of the cases which had come to his notice, recovery had taken place after the administration of arsenic. He was of the opinion that the assumption of the sarcomatous nature of the disease was not warranted by the microscopical structure of its lesions, nor by its clinical course. Neither does Köbner accept the views of the French dermatologists, who regard mycosis fungoides as possibly a variety of pseudo-leukemia, characterized by the development of cytogenous tissue in the skin. Sections of the cutaneous lesions, stained by Gram's and Lutzgarten's methods, gave no indication of the presence of any kind of microorganism. Inoculation of gelatine with fluids from the pathological tissues only gave rise to the development of cultures of staphylococcus aureus and albus. Köbner is of the opinion that the microorganisms discovered by Auspitz's assistants, Hochsinger and Schiff, in connection with mycosis fungoides, and supposed by them to be pathogenetic, are simply accidental, since they were found outside of the blood-vessels, and in sections taken from cutaneous lesions already deprived of epidermis, and thus presenting conditions favorable to the growth of ordinary and ubiquitous microorganisms. The streptococci, described by Rindfleisch and Hammer as existing only within the lymph and bloodvessels, he considers to be of post-mortem development, and similar to the micrococci found in the bloodvessels after death from septicæmia, which was the immediate cause of death in the patient who furnished material for the investigations of Rindfleisch and Hammer. Upon clinical grounds, however, the disease is to be regarded as one of the chronic infectious maladies, although the contagium or virus has not yet been demonstrated.

In the discussion which followed, Neisser stated that in three instances of granuloma fungoides, he had been able to constitute the presence in the cutaneous lesions of cocci, which, however, were found only in those portions of pathological tissue deprived of epidermis, and therefore their presence was to be regarded as fortuitous. Lewin also had been unable to detect the existence of any microorganisms in those lesions of mycosis fungoides which still retained their epidermal covering.

Dr. J. F. Payne<sup>2</sup> describes a case of mycosis fungoides occurring in a man fifty-seven years of age, the disease having existed about four years at the time of death. The clinical appearances and course of the disease were typical, and just before death there were "upon the body about fifty-seven tumors large and small, varying in size from half an inch to two or three inches in diameter. About one-half of these showed no distinct softening or ulceration, but eighteen were wholly or partially excoriated, exuding a moist discharge and ulcerating, while eleven were converted into distinct flat ulcers." The autopsy revealed no changes in any of the viscera, the disease being confined to the skin and subcutaneous tissues, and it is worthy of notice that the lymphatic glands were not affected. During the life of the patient attempts were repeatedly made to cultivate microorganisms by inoculation of sterilized gelatine with fluids and epidermal

scales taken from the pathological tissues, but without success. Microscopical examination showed the structure of the cutaneous lesions to be essentially that of a granulation tumor, and it was found impossible by brushing sections of these tumors, to demonstrate the existence of a reticulated connective tissue stroma, such as was first described by Ranvier. Repeated microscopical examination by several independent and competent observers, also failed to show the presence of any form of microorganism in these tumors. The author refers to the conclusions of Köbner with regard to mycosis fungoides as agreeing entirely with his own. These conclusions<sup>3</sup> are:

- (1) There are no microorganisms to be found in the tissues or blood, in this disease.
- (2) The supposed cocci of Hochsinger are granules of "Mastzellen."
- (3) The micrococci described by Rindfleisch are those found in septicæmia.
- (4) The micrococci cultivated by Hochsinger and Schiff, was probably nothing but staphylococcus aureus.

#### ERYTHEMA NODOSUM AND RHEUMATISM.

In a paper<sup>4</sup> presented to the Clinical Society of London, Dr. Stephen Mackenzie considers the relation of erythema nodosum to rheumatism, in connection with the analysis of one hundred and eight cases of the former disease collected from the records of the various London hospitals. Of these examples of erythema nodosum, eighteen occurred in males and ninety in females, and the period of life most obnoxious to the development of the disease was between the tenth and thirtieth years.

In thirteen out of these one hundred and eight cases or in twelve per cent. acute rheumatism coexisted with erythema nodosum, and in four instances subacute rheumatism was present, making seventeen cases in all, or fifteen and seven-tenths per cent. in which rheumatism and erythema nodosum coexisted. In addition to these there were also seventeen cases in which arthritic pains, apparently of a rheumatic character and not merely due to the cutaneous lesions, were present, making thirty-four cases altogether, or thirty-one and four-tenths per cent. in which rheumatism was found to be associated with erythema nodosum. With regard to the development or existence of endocarditis during the course of erythema nodosum, after quoting Dr. Barlow<sup>5</sup> to the effect that he himself had never been able to assure himself of the production of an organic cardiac murmur in erythema nodosum nor of any intercurrent arthritis, and that he did not consider the affection as closely allied to rheumatism, the writer mentions that of the one hundred and eight cases subjected to analysis, in four there was evidence of endocarditis in the shape of an organic murmur developed during the course of the attack, and twenty cases in which such a murmur was found to exist at the time of admission to the hospital. Dr. Mackenzie considers the above facts to warrant the following conclusions:

- (1) That erythema nodosum is frequently associated with definitely rheumatic symptoms.
- (2) That heart disease (endocarditis) may arise during an attack of erythema nodosum both in cases in which arthritis is present and in cases where there is no affection of the joints.

<sup>2</sup> Transactions of the Pathological Society of London, Vol. xxxvii, 1886, p. 522.

<sup>3</sup> Fortschritte der Medizin, September 1, 1886.

<sup>4</sup> Clinical Society's Transactions, Vol. xix, 1886, p. 215.

<sup>5</sup> British Medical Journal, Vol. II, 1882, p. 311.

(3) That these conclusions justify the inference that erythema nodosum is frequently, if not generally, an expression of rheumatism, even when no other definitely rheumatic symptoms are present.

#### UNIVERSAL ALOPECIA.

Dr. Tyson<sup>9</sup> reported to the London Clinical Society, three instances of universal alopecia. The patients were all strong and healthy males, unaffected with syphilis, and forty, forty-four and twenty-one years of age respectively. In one case the affection followed long-continued anxiety about money matters, and total and universal baldness occurred in ten days. The cause to which the second patient attributed his misfortune, was sudden fright occasioned by his being awakened from profound sleep by an unusually loud clap of thunder. His hair began to fall out shortly afterward and in two weeks he was entirely bald. He also lost the nails of the thumbs and great toes. The third patient was thrown from his horse, one month before his hair began to come out. He was struck violently on the head and since that time his memory became defective and he was at times exceedingly drowsy. In this instance, baldness was complete and universal in one month. These cases were presented to support the assumption of a neurotic origin of the universal form of alopecia areata, and also to demonstrate the fact that clinically speaking there are two forms of the disease. There seems to be little doubt but that mental trouble or physical injury may be sufficient to cause universal alopecia in a very short space of time. Dr. Dyce Duckworth has recorded an instance of universal alopecia due to an injury,<sup>10</sup> and Mr. Todd a case occurring after cerebral injury.<sup>11</sup> An example of rapid and universal alopecia mentioned in the second volume of "Holmes' System of Surgery," page 31, is interesting in this connection. A frigate was struck by lightning and the captain received at the time several wounds upon the head. The next day, while shaving, he found that the hairs instead of being cut by the razor, were torn out by the roots, and subsequently all the hair on the head and body was lost, while during the subsequent year, the nails of the fingers came away, but not those of the toes. This condition of things was permanent. The characteristics of this class of cases is as follows. The affection begins on the scalp, not necessarily in spots, and spreads rapidly until universal baldness is complete. It occurs in adults but not always in young adults as has been supposed. The prognosis is unfavorable, the more so the older the patient, and treatment has no effect whatever. The starting point of the malady can often be traced to a neurotic cause. These cases are entirely different from the ordinary type of alopecia areata which beginning in youth as scattered bald patches upon the scalp remains confined to this region, while the prognosis is comparatively good.

#### ALOPECIA AREATA.

Joseph<sup>12</sup> reported to the Association of German naturalists and physicians at their last meeting the results of some experiments which go to show the trophoneurotic origin of alopecia areata. Cats, in which the spinal ganglion of the second cervical nerve, together with a portion of the posterior and anterior

nerve roots, had been excised were affected in periods of time varying from five to twenty-seven days after the operation, with localized loss of hair. There appeared one or more spots of circumscribed baldness, situated in the cutaneous regions supplied by the occipitalis major and minor nerves, and by the auricularis magnus. The skin in the affected regions was of normal appearance, presenting no noticeable redness or paleness, and the loss of hair occurred in round, oval or oblong circumscribed areas of skin. These bald spots, which in the beginning were about the size of a ten-cent piece, increased gradually in size, eventually reaching that of a twenty-five-cent piece. Neither gross disturbances of sensation, itching nor any parasitic affection were to be detected in connection with these bald spots. Microscopic examination of the skin of the affected areas showed simply atrophy of the hair papillae, combined with complete lack of hair. The erector pili muscles and the sebaceous glands were found to be unchanged. The writer also brought forward as clinical facts which support the assumption that alopecia areata is of trophoneurotic origin, the discovery of Nachtigal that there may exist in the bald patches due to this disease a greater delicacy and acuteness of sensation than in other regions of the skin and the fact that in one instance mentioned by Michelson, there had been noticed by the patient for about three months before his hair began to come out a pricking, "going to sleep" sensation in the regions of the scalp, in which baldness ensued. An observation of E. Wagner is of interest in this connection. A patient who was affected with alopecia areata fell ill with the measles, and the eruption due to the latter disease did not make its appearance upon the areas of baldness. Analogous to this are those cases of hemiplegia in which the eruption caused by any intercurrent acute infectious disease, such as scarlatina or measles, does not appear upon the paralyzed side of the body. In the discussion of the subject which followed, it was the general opinion that alopecia areata is of trophoneurotic origin simply, and that instances of so-called inflammatory alopecia areata, attended with more or less redness, and desquamation or with desquamation alone, are in reality patches of tinea capitis. As to the micro-organisms discovered by some observers in connection with alopecia areata, and supposed by them to be pathogenetic, there is reason to believe that they are nothing more than ordinary cocci, to be found on healthy as well as diseased hairs. In support of this view, agar cultures of hairs, taken from healthy scalps, from the periphery of bald patches due to alopecia areata and also from the patches themselves, together with nodulated hairs from the axillae, were shown by Behrend. In all of those cultures made with different kinds of hairs, there were found the same varieties of micrococci.

#### METHOD OF EXAMINING EPIDERMIS IN ORDER TO DETERMINE THE PRESENCE OF FUNGI OR OTHER MICROORGANISMS.

The method employed by Bizzozero whose name is well known in connection with such examinations, is as follows: (1) The epidermal scales are first soaked in ether for twenty-four hours, in order to remove the fat. (2) A few drops of a fifty per cent. solution of acetic acid are then added to the epidermal scales on a cover or object glass, and the larger masses of epider-

<sup>11</sup> Lancet, vol. ii, 1869, p. 92.

<sup>12</sup> Vierteljahrsschrift für Derm und Syph., 1 Heft, 1887, p. 197.

mis are broken up with needles. (3) The acid should then be allowed to evaporate spontaneously or with the aid of a moderate application of warmth. The specimen is now ready for staining. For this purpose the following preparation may be used:

Concentrated alcoholic solution of methylene blue . . .	30 parts.
One per cent. solution of potassium hydrate . . .	1 part.
Distilled water . . . . .	100 parts.

A still better method of staining is Gram's differential method, as follows:

A few drops of gentian or methyl-violet solution in aniline water is added to the specimen, on a slide or

cover-glass, and allowed to act for from five to thirty minutes. The specimen is then washed with absolute alcohol, after which Gram's iodine solution is added to the specimen, or else the cover-glass upon which the specimen is placed, may be floated in the iodine solution for from one to five minutes. The preparation is then again washed in alcohol and dried, being now ready for examination, the fungi or micro-organisms which may be present being the only portions in which the coloring matter is retained. This method is given by Dr. Payne in the "Transactions of the Pathological Society of London for 1886," in connection with an article upon erythrasma.

### Clinical Memorandum.

#### ON EXAMINATION OF THE THROAT, WITH ESPECIAL REFERENCE TO THE MANNER OF USING THE TONGUE-DEPRESSOR.

BY JOHN W. FARLOW, M.D.

ANY one who has instructed students in examinations of the throat, must have noticed the great difficulty that is often experienced in depressing the tongue so as to get a satisfactory view of the pharynx, and, more particularly, how great an undertaking it is to hold the unruly member under control long enough to admit of the use of the rhinoscopic mirror. Whoever has had his own throat looked at, must have noticed how much easier it is to breathe quietly, and allow a thorough inspection of the throat, when the one holding down the tongue understands how to do it, than when some well-intentioned, but uninstructed, member of the family makes a number of desperate, but ineffectual attempts, which result only in gagging.

I do not propose to say anything about the use (only too common) of the spoon, lead-pencil, paper-cutter, or other domestic article, other than that the sooner they are given up, and a proper tongue-depressor sub-

FIG. 2.

stituted, the more satisfactory to both patient and physician will be the examination.

Let us suppose the patient to be seated in a comfortable position, before a good light. A few preliminary directions to him will be of great service. As soon as he is seated, he usually opens his mouth as widely as possible, contracts his throat, and thrusts out his tongue to its utmost extent, which, together with his grimaces, make him thoroughly ill at ease before a word has been said. He should be told, at the outset, not to open his mouth too widely, as a more moderate opening is much better. He should be particularly requested not to contract his throat or distort his face. In other words, he should open his mouth gently, a little wider than if he were to say "ah!" in his natural voice. The tongue should not be forcibly extended, but should rest against the inner side of the lower front teeth. Be sure that he does not hold his breath, as this only tires him.

It would seem as if it were easy to say "ah!" correctly, but here is another stumbling-block. It is usually formed in a contracted throat, and exploded as if it were the offending, foreign body which had caused the patient's grimaces when first opening his mouth. A good way is to tell him to say "ah!" after you sev-

eral times quietly. Not until you are satisfied that these preliminaries (seemingly trivial, but, in reality, of great importance) are well carried out, should you use the tongue-depressor.

What are some of the essential features of a good tongue-depressor? It should be simple in construction, so as to be easily cleaned, and not liable to get out of order or break. It should be firm, so that a strong tongue can be held down. Here is a source of weakness of the folding depressors. When the patient throws his head back, the tongue-holder tends to fold up, unless the outer blade is pulled forward. It should not be too large; otherwise, it would project too far back on the tongue, or take up too much room in the mouth. Many tongues are so large, that they need all the room they can get. Some lower jaws are so narrow as to admit only a rather small instrument between the teeth. It should not be too heavy, for it would tire the tongue. It is better to let the hand use what force is necessary, as it can do it intelligently and accurately. In order to hold the tongue better, and to make the instrument lighter, it is often fenestrated. This fenestra is sometimes so large, that the portion of the tongue which projects upward through it is of such size as to interfere seriously with the view of the pharynx. This is a fatal defect of the open-wire depressor. Another important point is that the blade should look clean, for which reason nickel-plated ones are better than hard rubber or iron. The handle should be one that can be firmly held, and, to my mind, indented wood or hard rubber is better than metal.

The instrument figured here (Figure 1) is no new pattern, but I introduce it as illustrative of some of the points of which I have been speaking. I have found it to serve a very good purpose, and, although this is the smaller size, I use it for both children and adults. It is nine inches long, and weighs not quite one-and-a-half ounces. The part that goes into the mouth is three inches long and one inch wide at its widest part. The greatest width of the fenestra is one-half inch.

The tongue-depressor should be taken firmly between the thumb and fore-finger (Figure 2). The patient should quietly say "ah!" and, during expiration, the instrument should be put into the mouth, till its end is a little farther back than where the tongue begins to curve backward and downward. Be careful not to put it too far back, but, at the same time, it should be far enough back, so that the base of the tongue can be drawn well forward. The middle finger, placed under the patient's chin, steadies the hand, and also holds the patient's head under control. The tongue is now depressed, and then its base drawn forward by lifting and pulling forward the handle of the instrument by the third and little fingers, the thumb and forefinger acting as a sort of fulcrum.

The head, tongue, and tongue-depressor are thus easily controlled by one hand, and the patient, feeling that he is firmly held, no longer tries to free his tongue and move back his head, and, consequently, is quieter, and gags much less than when he is held in the usual loose fashion.

In Figure 2, the left hand holds the instrument. It is better to use the left hand, so that the right may be free to use the rhinoscopic mirror, probe, or whatever is necessary to complete the examination or treatment.

— Dr. Olshausen of Halle, succeeds to the chair of Prof. Schroeder at the University of Berlin.

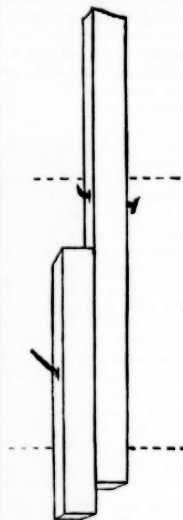

## Hospital Practice.

BOSTON CITY HOSPITAL.

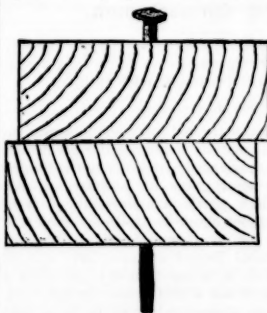

### A CASE OF SEVERE PERFORATING WOUND OF THE THIGH, WITH OTHER INJURIES. RECOVERY.

SERVICE OF G. W. GAY, M.D.

REPORTED BY OLIVER H. HOWE, M.D., FORMERLY HOUSE-SURGEON.

as he fell. The slats entered behind and a little below the great trochanter of the right thigh and passed through the thigh, behind the femur, to a point at the inner side, just below the scrotum, where the square ends projected about an inch and a half.

quarters of an hour and was finally released by a policeman.

He was brought to the hospital with the slats (in all, about eleven inches long) in his thigh. The slats were one and seven-eighths inches wide and three-fourths of an inch thick.

Ether was given, and Dr. Bolles, who happened to

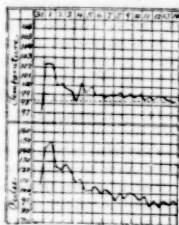

On the morning of January 31, 1886, J. F., a boy sixteen years of age, employed as a telegraphic line-man, was walking upon the roofs of buildings in the city. The roofs were covered with a light coating of snow, which had freshly fallen. Owing to this fact, he stepped upon a skylight, which gave way under him, allowing him to fall through a ventilating shaft, a distance of four stories (forty-two feet, by measurement), to the ground floor below. At the bottom of the shaft (on a level with the ground floor) were piled up a number of old bedsteads and projecting vertically from this pile was a bed-slat with a shorter piece of the same roughly nailed to it, two nails projecting at nearly right angles. Upon the square ends of these slats, the boy's thigh was impaled

The boy hung, impaled in this way, partly supporting himself by standing on his left leg, until his cries brought assistance to the spot and he was released by the slat being sawed off below. As the place where he fell was difficult of access, he is said to have hung there from half to three-

be nearest at hand, removed the slats from the thigh, after having pulled out one of the nails.

On the inside of the thigh was a ragged wound about three inches long. On the outside (at the point of entrance) was a V-shaped wound, each arm of which was about three inches long. The muscles were badly lacerated and the sheath of the great sciatic nerve was laid bare for a distance of about three inches.

Dr. Gay, to whom the case had been assigned, now being present, cleansed the wound, inserted two drainage tubes (one passing through the thigh) and closed both wounds with wire and shirt-button sutures and accessory silk sutures. The whole was done antiseptically and a dressing of iodoform gauze applied.

The boy was found to have a comminuted fracture of the lower third of the right scapula; also two scalp wounds, each an inch long, neither exposing the bone. After recovery from ether, the boy was not much collapsed and had very little pain. The next day he was delirious, with temperature of 102.4 and pulse of 150. The temperature just mentioned was the highest ever reached during his stay in the hospital.

The second day after entrance, there was considerable diffused redness about the wounds and the flaps were very tense, triangular flap on outer side beginning to slough. No chill. Antiseptic dressing is changed temporarily for a poultice. Two wire sutures removed. That night he got out of bed in delirium. A little pus about wounds.

6th day. Resume antiseptic dressing again, as the cellulitis has subsided. Very restless at night and tries to get out of bed. All sutures have been removed from thigh.

8th day. Delirium has ceased. Scalp wounds have healed by first intention.

13th day. Slough proves to be superficial only and has wholly separated. Granulations healthy throughout; only slight amount of pus. Outer wound, which has been gaping badly, is now held together by a strip of adhesive plaster. Tubes removed. General condition very good.

21st day. Has had very little pain from scapula, and it can now be moved without pain. Union appears to be firm.

35th day. Cavity has been steadily filling up with healthy granulations.

53d day. Wound on inside of thigh entirely healed; that on outside now superficial. Dressing changed to soda wash.

59th day. Sitting up for first time.

65th day. Walks without limping.

69th day. Wound only the size of a silver three-cent piece. Leaves hospital with dressing of simple cerate.

Since discharge he has reported several times. The wound was soon entirely healed. With exception of slight stiffness of the injured thigh, he has had no inconvenience remaining from any of his injuries and has resumed his former occupation of telegraphic lineman.

## Reports of Societies.

### PROCEEDINGS OF THE NORFOLK DISTRICT MEDICAL SOCIETY.

S. ALLEN POTTER, M.D., SECRETARY.

MEETING March 30, 1886. DR. JOSEPH H. STREETER in the chair.

DR. C. E. STEDMAN read a paper upon,

#### A CASE OF GANGRENE OF THE LUNG.<sup>1</sup>

The discussion was opened by DR. J. H. STREETER, who described two cases of gangrene of the lung which had come under his own observation.

The first occurred in the practice of the late Dr. Henry A. Martin.

The patient was a man of between sixty-five and sixty-eight years of age. His illness lasted from five to six months, and was marked by periods of alternate improvement and decline. There were hemorrhages from the lungs, at first slight, later severe. There was noticeable absence of prostration, a fact to be especially remarked, for in gangrene of the lung great prostration is the rule. The man finally died.

The second case occurred in Dr. Streeter's own practice. It was that of a merchant, who presented at first the trifling symptoms ordinarily referred to as "a cold." One morning, however, on attempting to rise from bed, he felt faint, and had a slight chill. This passed, and the only notable symptoms remaining was an unaccountable prostration. On the afternoon of this same day, a transitory pain was felt under the right scapula, but no physical signs were discoverable. The prostration, however, continued, and in three or four days the breath became very fetid. On the tenth day, during a severe attack of coughing, a plug of fetid material, about two inches long and as large round as a lead pencil, was expectorated, and from that moment the patient began to improve.

The long continuance of the extreme prostration, and fetid breath, led the speaker to think that the disease had not been confined to a bronchus, but that the mass had originated in the parenchyma of the lung and been lodged in a bronchus some time previous to expulsion.

DR. H. W. BROUGHTON described a case of circumscribed gangrene of the lung, which had been treated by himself, and reported in the *Boston Medical and Surgical Journal* of February 21, 1884. The patient showed at first the symptoms of ordinary pneumonia, except that in place of the usual single chill, there were several. When resolution was expected, there occurred fetor of the breath, a sputum nearly black, and profound prostration. Empyema soon followed upon the same side as the pneumonia. A permanent opening was made and fetid pus removed. The patient recovered.

The reader, in closing the discussion, called attention to the fact that in his case the severity of the symptoms was by no means commensurate with the gravity of the disease. Prostration was not great, fetor not very marked, cough and expectoration scant, temperature not high, and the pulse, upon which one relies most in acute diseases, not rapid.

— The State of Ohio claims to have sixteen institutions licensed to confer the degree of M.D.

<sup>1</sup> See page 441 of the Journal.

## THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, April 7, 1887.

DR. A. P. GERSTER read a paper on

## THE PROPER SELECTION OF ETHER OR CHLOROFORM AS AN ANÆSTHETIC.

In approaching this subject, he said it was necessary to cast away all prejudice, considering it in a spirit of candid inquiry. In the first place, it was to be borne in mind that both ether and chloroform were dangerous anæsthetics. Researches with the aid of the sphygmograph, demonstrating the effect upon the pulse, had shown, however, that chloroform was infinitely the more powerful agent of the two. Still, this fact did not afford ground for the universal condemnation of chloroform, though it rendered greater caution necessary during any operation in which it was used. But, while chloroform was the more powerful agent, and, consequently, attended with more danger at the time of the operation, its employment was not followed by the secondary affections of the lungs and kidneys which were apt to result from that of ether.

The statement frequently made by partisan zealots, that ether is always, and under all circumstances, safe, was not true. In hospital practice, it was found that in a considerable number of patients, particularly those addicted to the use of alcohol, it was exceedingly difficult to produce profound anæsthesia with this agent, and in such cases, from the effect of the excessive and irritating mucous secretions excited, catarrhal or septic pneumonia was very apt to ensue. Admitting that, on the whole, ether was safer than chloroform, Dr. Gerster proceeded to speak of the manner of administration, and recommended, as superior to any other, that by means of Ormsby's inhaler. He then went on to say that ether was contra-indicated in all affections impairing the renal function, a circumstance the credit for first pointing out which belonged to Dr. Emmet. Having referred to cases showing the danger of ether when nephritis was present, he expressed the opinion that an examination of the urine should be made in every case before administering an anæsthetic, except where the urgency of the circumstances precluded this; when, if Bright's disease was discovered, chloroform was to be preferred as the safer agent.

Ether, he said, was also contra-indicated where, in the aged or in young children, or generally in the feeble, there were catarrhal conditions of the air-passages. Having related three cases in his own practice, in which he claimed that fatal or dangerous pneumonia was set up by ether in patients suffering from cancer, he stated that, in the year 1886, three cases of pneumonia occurred after the administration of this agent in the Mount Sinai Hospital, in two of which the patients died, while in the third recovery took place. There were also five cases of severe bronchitis, arising under similar circumstances, reported during the year. Dr. Gerster said he had four more cases in his notes, but, as these operations were performed either upon the trachea, larynx, or lower jaw, it was possible that the entrance of blood into the air-passages might, perhaps, have caused the trouble, and he would not, therefore, insist on these. As anæsthesia by ether was dangerous in young children suffering from affections of the air-passages, chloroform was always to be preferred under these circumstances, although, in healthy children, ether was borne well.

The third class of patients in which chloroform was to be preferred was those who could not be satisfactorily brought under the influence of ether. In the incomplete anæsthesia caused by it, there was an amount of muscular rigidity remaining, which constituted an insuperable difficulty in quite a large class of cases. Not only loss of sensation, but total relaxation of all the voluntary muscles, was indispensable in many operations; and, in spite of proper preliminary precautions, and the greatest amount of care in the administration of the anæsthetic, in 11 cases out of 125, at the Mount Sinai Hospital, it was found impossible to produce, with ether, the complete anæsthesia required. In all these instances, however, a change to chloroform was attended with the happiest results. Recapitulating, he said, then, that ether should not be used as an anæsthetic in any case (1) where acute or chronic nephritis is present, or is suspected to exist. (2) Where there is any chronic pulmonary affection, especially in the aged or feeble. (3) Where ether will not produce the complete anæsthesia and relaxation indispensable for the successful performance of the operation in question.

Dr. Gerster then went on to say that while, in general, the administration of chloroform undoubtedly required greater caution than that of ether, there was only one contra-indication against chloroform, namely, the presence of a fatty or weak heart. In the hands of a careless giver of anæsthetics, chloroform was, no doubt, more dangerous than ether, but Bright's disease offered no contra-indication to chloroform. In eight years' hospital experience, he had met with but two cases in which pneumonia followed the administration of chloroform, and in both of these the probable cause of the pulmonary trouble was the entrance of blood into the bronchi. The existence of valvular disease of the heart, again, was not a contra-indication to chloroform, provided there was satisfactory compensation by muscular hypertrophy. On the other hand, if the heart were feeble from any cause, chloroform should never be used. In anæmia, also, ether was, as a rule, safer.

He next spoke of the special danger of chloroform in cases of marked nervous depression, and said it should never be used when the patient was in a state of fright. It was a fact that most of the deaths from its use were in cases of slight operations, and he thought this was explained by the dread of the operation or the anæsthetic. In severe operations, the patient generally nerved himself for the ordeal, and hence there was less danger from this source.

On February 10, 1886, Thomas R., aged thirty-two years, consulted Dr. Gerster, at his office, for a tumor on the lower part of the face. When an exploratory incision was proposed, he became so much alarmed that he begged for chloroform, which was not given at this time. Five days later, he was admitted at Mount Sinai Hospital as a private patient, and on the 17th, Dr. Gerster proceeded to operate on the tumor, which proved to be a glandular abscess. He subsequently learned that the patient expressed the conviction that he would never leave the operating room alive. When two drachms of chloroform had been administered, by means of Esmarch's mask, opisthotonos suddenly occurred, the pupils became dilated, and the abdominal muscles were found to be rigid. The pulse ceased, and within a minute the patient was dead, all efforts at resuscitation proving futile. The experience gained

in this case, he said, had led him to administer stimulants and a small dose of morphia prior to operating in all cases where the patient was not in perfectly good condition, and he would now never give chloroform to any one who was the subject of deadly fear. In every instance in which it was feasible, a careful physical examination should be made, and the probable prognosis duly announced to the patient or his friends before proceeding to employ this anæsthetic.

## DISCUSSION.

DR. A. JACOBI, the President, read a letter from Dr. H. Knapp, who was unable to be present, in which he briefly related his personal experience with the two anæsthetics. From 1860 and 1874 he used chloroform in over three thousand cases. While he had had no fatal result, in many instances the effects were very unpleasant, and he had met with a considerable number of critical cases. During this period about once a month he was obliged to resort to artificial respiration and other measures for the resuscitation of his patients. Since the year 1874 he had used ether exclusively, and since then he had found no ground for complaint, and no contra-indication for the administration of this agent. It was his practice to employ what is known as the "choking plan" in giving it; though at the beginning of the anæsthetization the patient was allowed to have enough air to prevent the sensation of strangulation often complained of by those taking ether. He had found that many operations performed by the ophthalmic surgeon could be completed during preliminary anæsthesia, that is, before profound narcosis was induced. In several hundred of his cases the average duration of the maintenance of the anæsthetic was one minute and thirty-seven seconds. He had met with no fatal cases, and only a very few in which there was any trouble whatever on account of the anæsthetic. The secondary effects, moreover, he had not found any more unpleasant than those of chloroform. On the whole, therefore, he regarded ether as an invaluable anæsthetic, and he looked upon it with special favor from the fact that, now that he habitually employed it his mind was quite free from that feeling of anxiety as to the effect of the anæsthetic which in the case of chloroform he could never overcome.

DR. ROBERT F. WEIR said that there seemed to be a growing feeling in the minds of the profession that ether is not as safe an anæsthetic as we have for many years been supposing. The points presented by Dr. Gerster were certainly worthy of consideration, but he thought he had stated the case too strongly against ether. While, in some instances, kidney trouble might be aggravated by the administration of this agent, he had seen too many cases of this kind, in which it had been given with safety, to make him willing to acknowledge that the presence of nephritis was always a contra-indication to the use of ether. He did think, however, that in such cases it should be given with special caution.

Dr. Gerster was perfectly correct in his statement that there were a certain proportion of cases in which it was practically impossible to produce perfect anæsthesia with ether. He could not, however, recall a single case in which the patient took ether badly, as it was generally expressed, when the operation had to be postponed on this account. By summoning aid to assist in holding the patient, he had always been able to

get along, also, without resorting to chloroform. As to the production of pneumonia, while it was possible that this might sometimes be due to the local effect of the cold ether vapor, he was inclined to think that, in many instances, it was directly attributable to the exposure of the patient's person in carrying out the antiseptic measures now so generally in vogue. Some time ago, he had called the attention of the house-staff of the New York Hospital to the matter, directing warm and dry towels to be placed next the body, except just at the seat of operation; and, since this precaution had been taken, he had met with less trouble of the kind in question.

Personally, he did not think the bad consequences arising from the use of ether were as frequent as had been represented in the paper; but, after all, Dr. Gerster had admitted very frankly that chloroform was much more dangerous than ether at the time of administration. The question then arose: Is the danger which follows the use of ether greater or less than the danger which attends that of chloroform during the operation? Dr. Weir answered this by saying that, for himself, he would prefer to take ether rather than chloroform, if an anæsthetic were necessary, even if he were the subject of kidney trouble. The deaths from chloroform, from 1873 to 1879, collected by the *Lancet*, amounted to 92; while those from ether, from 1873 to 1880, as collected by Dr. Roberts, of Philadelphia, amounted to only 18. This showing, he thought, corroborated the position which he took.

In the New York Hospital, ether and chloroform had been used since 1847. Shortly after this date, however, a number of mishaps occurred in connection with chloroform, and, since 1850, ether alone had been employed. From 1847 to 1870, when the old hospital on Broadway was closed, some 7,700 operations were performed under ether, and in only three of these was a fatal result attributed to the anæsthetic. From 1876, when the new hospital buildings were opened, to 1886, 2,289 operations were performed under ether, with one death from the anæsthetic. In the House of Relief, from 1876 to 1886, 802 operations were performed under ether, with one death from the anæsthetic; and it would thus be seen that, at the New York Hospital, there had been only five cases of death from ether in nearly eleven thousand operations. Until an anæsthetic free from all objections was discovered, he thought, therefore, we could go on with the use of sulphuric ether with a considerable amount of confidence and satisfaction.

DR. LEWIS A. SAYRE stated that he was well aware that the views which he entertained on this subject were widely different from those held by the great majority of the profession in New York; but, in spite of opposition, he had for many years continued to hold them with ever-increasing confidence. He preferred chloroform, because it was agreeable to take, speedy in action, excited no spasmodic rigidity, and was not followed by the bad effects which were sometimes noted in the case of ether. It was the usual practice to allow the patient to have plenty of fresh air with the chloroform, thus permitting its antidote to act directly against the anæsthetic. In consequence, a much larger quantity of chloroform was taken into the system than was required if the proper manner of administering it were employed. The method of pouring an unmeasured quantity of an anæsthetic into a cone or inhaler, and then, every few minutes, adding an ounce

or two more, he thought was entirely wrong. We did not, he said, use strychnia, arsenic, morphia, or other potent agents in this careless way. Chloroform and ether were both powerful drugs, and he thought, therefore, that they should be used with the same caution as any other potent agent.

Dr. Sayre then exhibited the inhaler, or modification of Lente's, which he had used exclusively for many years. By means of a rubber attachment, it could be made to fit any face in a perfectly air-tight manner, so that the patient was not allowed to breathe any air, except that which was permeated with the anæsthetic. Ten, twenty, or thirty drops of chloroform, poured in upon the sponge with which the cup was provided, would almost invariably produce anæsthesia; and if, from any cause, the heart should show signs of weakness, a few expirations caused by artificial respiration would be sufficient to get rid of the entire amount of chloroform, and thus save the patient. When chloroform was freely mixed with air, anæsthesia was not produced for a long time, and great injury was liable to result from the violent muscular exertion made by the patient, especially when there was a joint-disease present. In addition, if, in any case in which chloroform was given in this way, trouble should arise from the anæsthetic, a fatal result would probably ensue, on account of the large quantity of the drug which it had been necessary to administer before anæsthesia was produced.

Dr. W. G. WYLIE said that, as a rule, he preferred ether, but thought there were many cases in which it was advisable to use chloroform. There could be no doubt that ether was often given altogether too carelessly, and this was probably due to the prevalent impression that there was little danger to be apprehended from this agent. Some years ago, he had heard a new interne at Bellevue Hospital, who had just nearly lost a patient while taking ether, remark that he "didn't know that a person could be killed from ether." Like most other members of the profession in New York, Dr. Wylie said that he had used ether almost exclusively in surgical cases, though he had always employed chloroform in his obstetrical practice, and, until two months ago, had never met with any trouble from ether. At that time he operated on a patient with a large abdominal tumor, using ether as the anæsthetic. The urine had been previously examined, and found to contain no albumen; but not long after the operation the patient died of Bright's disease, an attack of acute nephritis having supervened upon chronic interstitial nephritis. In this instance, he thought that the administration of chloroform would not have been followed by the disastrous results which were caused by the ether.

Since then he had been called upon very suddenly to operate in a case of strangulated umbilical hernia. The patient was very stout, and became cyanotic while taking ether. She nearly died on the table, but rallying to some extent, died about an hour afterward, apparently from suffocation. If another case of this kind presented itself he thought he would try cocaine, as he had come to the conclusion that ether was very dangerous in very fat women. The lung capacity was so small that any extra strain upon the lungs would be apt to prove fatal, for the presence of even a very little fluid in the trachea might be attended with serious danger.

There was another point which he thought was of

some value. He had found that patients who had taken ether more than once were apt to acquire a certain tolerance of the drug; so that it was often very difficult to get them under its influence. He had had an opportunity of observing this a number of times at the Woman's Hospital, where patients with troubles like vesico-vaginal fistula had to undergo several successive operations. He had to confess that three or four years ago he was more or less prejudiced in favor of ether in almost all cases, but he had now modified his views to some extent; so that if there were any trouble about the lungs or kidneys he would use chloroform.

Dr. WEIR remarked that it had been shown that operations for hernia, and upon the peritoneum in general, had of themselves a direct effect upon the kidneys, independent of the anæsthetic used for the operation.

Dr. JOHN A. WYETH said that he had formulated his views as to the cases in which the use of chloroform was justified as follows:

- (1) In children under six years of age, where it is less apt to cause an accumulation of mucus in the trachea and bronchi than ether. Its more rapid and less irritating action renders it preferable in this class of cases.
- (2) In women in childbirth, where the recumbent position is imperative.
- (3) In an emergency where ether cannot be obtained.
- (4) In a patient who had previously been in ether narcosis, in whom dangerous symptoms were caused by the ether.
- (5) In an emergency where it becomes necessary to perform an operation within two or three hours after the ingestion of solid food.
- (6) In some exceptional cases of laryngeal or tracheal stenosis.

In regard to the existence of nephritis, he would not consider this a positive contra-indication against ether. When this was present, however, he would always proceed with unusual caution, and if any trouble should arise, he would change to chloroform. He entirely agreed, in the main, with what Drs. Knapp and Weir had said. In his own practice he said he had used ether exclusively, except in the classes of cases mentioned, and although his experience had been quite extensive, he had not met with a single case of trouble from it. He had never seen such cases as those referred to by Dr. Gerster. Some of the operations mentioned by him in which ether was followed by such disastrous results were very long and tedious, lasting from three to six hours, and in individuals suffering from cancer; so that a fatal termination would not have been a matter of surprise under any circumstances. In his work on surgery Agnew had collected statistics which showed the deaths from chloroform and ether respectively to be in the proportion of sixty-five to one. Moreover, in half of the deaths attributed to ether in these statistics a mixture of ether and chloroform was employed. As to the good results which Dr. Sayre had met with from chloroform, he believed that his experience with it had been to a large extent confined to young children and parturient women.

Dr. ROBERT ARBE said that he had seen but one death from ether. It was a case of tetanus in which the late Dr. James L. Little was performing amputa-

tion of the leg, and the patient died, apparently from spasm of the heart, before the operation was completed. It seemed to him that ether was preferable to chloroform from the fact that the two principal dangers which had been urged as objections against ether, namely, the possible occurrence of acute pneumonia and acute nephritis were to a large extent under the control of the physician; while the dangers incident to chloroform were entirely beyond control. When asphyxia occurred during ether narcosis the use of artificial respiration and other appropriate measures were usually successful in restoring the patient, and if acute nephritis occurred after the employment of this anæsthetic, it was in his opinion amenable to treatment by such agents as sinapisms, digitalis, acetate of potassium, and, possibly opium. He had never seen a case of this kind in which death resulted. With regard to acute bronchitis and pneumonia, he believed that many of the cases following operations were due, not to the ether which had been employed, but to the exposure of the patient in being carried from the operating-room and in draughty wards. If such troubles were caused by ether, he thought that we should meet with laryngitis much more frequently than is actually the case. During the three years that he had spent at St. Luke's Hospital, seeing both medical and surgical cases, he had found that acute pneumonia arising in the hospital was more frequent in the medical than in the surgical wards. These considerations, he said, gave him great confidence in the use of ether, although he quite agreed with some of the other speakers that when chronic nephritis was present, it should be administered with great caution.

DR. P. F. MUNDÉ said that in his earlier professional career, spent abroad, he had been accustomed to use chloroform, and that since he had been practising in New York he had used ether almost entirely in surgical cases. He had seen no deaths or subsequent bad effects from the latter, either in his own practice or that of others. He had, however, on three occasions — twice in children and once in an adult — met with cases in which death would have resulted from the primary effects of the ether if artificial respiration and other active measures had not been resorted to. While he had been trained to use chloroform exclusively he would confess that he felt ether to be safer, if it was properly administered. The giving of the anæsthetic was, in his opinion, often a more important point than the operation itself. He therefore thought it was entirely wrong to entrust so serious matters to young hospital internes with little or no experience, since to administer an anæsthetic properly required as much experience as to assist intelligently in the actual performance of an operation.

The method for giving ether which he preferred, was by means of Clover's inhaler, in which the amount of air admitted could be carefully regulated. He had seen some cases which could not be well anesthetized with ether, and therefore when he noticed that the mucous membrane was particularly sensitive, he generally substituted chloroform for it for a time, and then afterwards went on with the ether again. He almost always gave bromide, and sometimes a hypodermic injection of morphia, preparatory to administering the anæsthetic. He was inclined to think, however, that morphia might possibly sometimes increase the danger. For short operations, and also in

the case of children, as well as in obstetrical practice, he preferred chloroform to ether.

DR. R. W. AMIDON said that while, as Dr. Gerster had stated, the only real contra-indication against chloroform was a weak heart, it was at the same time true that deaths occurred under it more unexpectedly — often, indeed, without any warning whatever — than when ether was used. In a note in "Holmes' System of Surgery," Dr. J. C. Reeve had said very truly: "There is danger attending the use of chloroform which no foresight can discern, no precaution avoid, and no skill avert."

As to the collection of mucus in the air-passages which Dr. Gerster had referred to as liable to cause such unpleasant and dangerous results when ether was used, this could readily be avoided by the preliminary hypodermic injection of atropia, as he had pointed out in a paper which he had read by invitation two years ago before the New York Surgical Society. When, therefore, any respiratory impediment was anticipated from the effects of the ether, from one-fiftieth to one-thirtieth of a grain of atropia should be administered. By this agent the bronchial and tracheal secretions are diminished, and it also tended to increase the activity of the respiratory centres and strengthen the heart. Dr. Thallen, of Brooklyn, and Dr. Weir had employed atropia to a considerable extent in this connection, and quite recently a case had been reported in the *Medical News*, in which impending death was averted by the administration of digitalis and belladonna.

DR. THALLEN, of Brooklyn, like most of the other speakers, thought that Dr. Gerster was too strongly in favor of chloroform. He agreed with Drs. Weir and Wyeth that the presence of nephritis should not be considered a positive contra-indication against the use of ether, although it should make us cautious in giving it. He related a case which had nearly died from the effects of ether in the hands of Dr. Emmet, and which afterwards came under his own care. After an examination of the urine and the heart, he determined to give ether for an operation that it was necessary to perform, and the patient took it without experiencing any trouble either at the time or subsequently. Still later she took chloroform, and this likewise was unattended with difficulty. He thought, as Dr. Sayre had suggested, that the administration of anæsthetics was largely a question of dosage.

The apparatus which he had adopted he regarded as far superior to Clover's or almost any other, and it was simply the ordinary inhaler used by dentists for nitrous oxide gas. As in the case of the inhaler exhibited by Dr. Sayre, at each inspiration the anæsthetic was inhaled, while the expiration got rid of the foul air. By means of this apparatus he had been able to keep a patient anesthetized for hours, and yet had not used more than a quarter of a pound of ether altogether. With it he had never had any kicking or struggling on the part of the patient, or failed to secure complete anesthesia. There was much ignorance in the profession, he thought, as to the proper administration of anæsthetics, and the ordinary way of giving ether was little less than brutal. The point suggested by Dr. Amidon seemed to him one of great value. He had first seen the idea proposed in the *Lancet* in 1880, if he remembered rightly. It was well known that atropia was one of the best stimulants to the respiratory centres, and it was therefore a valuable prophylactic in this connection.

DR. GERSTER in closing the discussion, said that he regretted that he had been charged with partiality, when he had endeavored to present an entirely unbiased opinion, and that his position had been misunderstood. He had not defended chloroform; but he did mean to say that it was unscientific to claim that either ether or chloroform was, so to speak, "our only salvation." The proper choice of the anæsthetic in each case, should be left to the intelligence and experience of the surgeon. Whatever might be the case with others, he himself had certainly met with a certain proportion of instances in which he could not properly anæsthetize the patient with ether. He had not hesitated to say, however, that he considered ether safer than chloroform, and that it should be preferred to it as a rule. Still, he did not think the statistics which had been quoted altogether reliable, from the fact that while in fatal cases from chloroform the patients died while upon the operating-table, and were thus sure to attract public attention; in many of those where ether was the cause of death the fatal issue did not take place for some time after the anæsthetic was given. He himself knew of a number of cases of death from ether which had never been published.

### Recent Literature.

*Refraction of the Eye, its Diagnosis and the Correction of its Errors.* By A. STANFORD MORTON, M.B., F.R.C.S., etc. Third edition, revised and partly rewritten. pp. 67. Philadelphia: P. Blakiston, Son, & Co.

It is hardly necessary to enter into an extended review of this well-known little book; it is, as its title indicates, a practical guide for the correction of errors of refraction. The chapter upon retinoscopy has been almost entirely rewritten, and in its present form is the best exposition of the diagnosis of errors of refraction by this method, that we have seen. There has been added to the book a series of new test-types.

M. S.

*Manuel Pratique de la Vaccination Animale.* Par L. VAILLARD. Paris. 1886. p. 73.

This excellent little treatise contains the principles of animal vaccination, clearly and concisely stated. The subjects treated are the objects and advantages of animal vaccination, the implements required, the choice of animals, method of inoculation, evolution of the eruption, collection and preservation of virus.

The author follows quite closely the instructions laid down in the larger work of Warlomont. The advice given by the French authorities, as to the preservation of lymph upon ivory points by a coating of mucilage of gum arabic, has two decided objections, namely, the insolubility of the gum as compared with that of dried lymph, and also the liability to employ it as a diluent, substitute or adulterant.

*Fifteenth Annual Report of the Local Government Board. Supplement.* 1885-1886.

This report comes, like its predecessors, replete with valuable papers upon topics connected with public hygiene. Some of its reports have appeared before, and received comment in the JOURNAL, notably the paper upon "Milk-Scarlatina at Hendon."

The statistics upon vaccination show that, of the 890,780 born in the previous year, 762,080, or 85.6

per cent., had been successfully vaccinated, and 81,955, or 9.2 per cent., had died before they could be vaccinated; 1,102 had been registered as insusceptible, 93 contracted small-pox before they could be vaccinated, and 87,440, or 4.2 per cent., were unaccounted for.

These results, as compared with those of previous years, do not seem to show that the anti-vaccination tumults at Leicester and elsewhere had produced much effect on the percentage of vaccinations in England.

Dr. Cory, by careful observations, shows that the "keeping" qualities of bovine lymph are fully equal to those of the humanized lymph, having obtained some successful results from tubes kept upwards of two years.

Mr. Powers gives further observations as to the effect of the Fulham small-pox hospital upon the surrounding neighborhood. Since his former report in 1881, the administration of the hospital had been improved in several directions. Measures were adopted to restrict, as much as possible, the communication with the outside world. An ambulance service was provided, and the number of the sick in hospital at any one time was limited. The conclusions, which he states after a careful estimate of the cases which occurred in the region adjacent to the hospitals, in the epidemics of 1880-81 and 1884-85, are that the changes in the administration of the hospital had little or no influence upon the quantity of small-pox distributed in the recent epidemic, through hospital agency, over the houses of the neighborhood.

Dr. Klein contributes further observations upon the pathology of foot-and-mouth disease; upon the etiology of tuberculosis; of the infection of fowls by human tubercular sputa; and upon the germicide power of bichloride of mercury upon pathogenic and non-pathogenic microorganisms. Mr. Laws contributes a paper upon the growth of the bacillus anthracis in vacuo, and upon its thermal death-point. Other papers follow upon the disinfectant properties of oxygen and ozone, and also upon the changes noted in the aëration of water, as indicating the nature of the impurities represented in it.

*A Companion to the United States Pharmacopœia.*

Being a commentary on the latest edition of the "Pharmacopœia." By OSCAR OLDBERG, Pharm. D., and O. A. WALL, M.D., Ph. G. Second revised edition. 650 illustrations. viii. 1216. New York: Wm. Wood & Co. 1887.

This work, by two of the members of the Committee of Revision of the United States Pharmacopœia itself, contains the description, properties, uses, and doses of all official and numerous unofficial drugs and preparations in current use in the United States, together with practical hints and working formulas. It is designed to be a ready-reference book for pharmacists, physicians, and students, yet it does not, as some other commentaries, repeat so much of the United States Pharmacopœia itself, being intended to serve rather as a companion and supplement to that work, than as a substitute for it.

Most of the illustrations are original drawings by Professor Wall, from actual specimens. A chapter is devoted to practical suggestions upon the use of the microscope in pharmacognosy, and the microscopic structure of plants is briefly treated. It contains practical information relative to the preparation and use of hypodermic and other injections, as well as inhalations, baths, and other forms of medication not usually referred to in books of similar description.

THE BOSTON  
**Medical and Surgical Journal.**

THURSDAY, MAY 12, 1887.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES & COMPANY,  
94 BOYLSTON STREET, BOSTON, MASS.

THE HYGIENE OF APARTMENT-HOUSES.

WHEN in the course of the settlement of any community the price of land available for residential purposes rises above a certain limit, it is inevitable that the increasing tendency towards a concentration of domiciles should reach a point where the dwellings must be superimposed upon one another. Hence the genesis of the apartment-house.

The "tenement-house" the earliest link in the evolutionary chain, of which the latest is the apartment-house, has long been in our larger cities the stumbling block of the social philanthropist and the thorn in the side of the dispensary physician. Much remains to be desired in the condition of these caravanseries for the poorer classes, and yet the vigilance of local health boards is gradually eliminating the worst of these breeding places of disease and foci of degradation. Capitalists are even finding out that it can be made to pay to provide comfortable and hygienic quarters for the class of people whose earnings are two dollars a day or less.

For the more favored class, peculiarly, apartment-houses are now becoming more and more of a necessity, and the objections which were urged against these buildings when they first began to come into use, are, we believe, being found less cogent. Perhaps no one would deny that a detached suburban residence is hygienically preferable for a growing family to an apartment-house. But the former is in many cases, for reasons economic or social, the less feasible alternative, and the important fact should be remembered that the device under consideration usually enables people to live with greater comfort and hygienic advantage than would otherwise be attainable for them in the same topographical locality. In the best of these houses the elevator and fire-escape give to the fifth or sixth story very reasonable accessibility and safety, while the view, the sun-light and the pure air, free of dust, enjoyed by their denizens are very positive elements on the credit side of the hygienic trial-balance.

There are unfavorable elements, some of which are perhaps essential to the structure, intrinsically, as for instance, dark rooms giving upon narrow well-spaces or against blank brick walls, but most of which are confined to the cheaper grades of buildings. One almost universal fault is the lack of ventilation in the common hall-ways and corridors. Few such buildings which we have seen, are free, as one ascends the stairs, from a more or less close and stifling or malarious atmosphere. In many cases this unfortunate state of things is directly favored by the atrocious structural blunder of making the bath-rooms on the successive floors dependent for light and ventilation upon small windows opening into these common passageways.

The item of noise is susceptible of great mitigation through the materials introduced into the floors and partitions of the better class of buildings, though there are few structures in which the endeavors of the too zealous musician are strictly confined to the room that gave them birth.

The heat which is usually supplied to the apartments is sometimes erratic in its distribution, and tenants who are sick or for other reasons are obliged to be up at night, may find that the janitor, either as a reflector of the thrift of the landlord or else as a delinquent in his own proper capacity, has left no source of caloric available for these hours.

In buildings devoid of an elevator, convalescents from sickness are often unable to get out of doors at as early a period as the degree of their recovery would otherwise allow. The same difficulty occurs in the way of the daily airing of young children, of whom the apartment-house usually contains a large proportional contingent, on account of special adaptation of such quarters to young married couples. Yet as a matter of fact not only the most expensive apartment-houses, but many of very moderate cost, do contain elevators, while that convenience is the exception in detached domiciles of corresponding grade, so that the climbing of stairs, which is the bane of the female sex in most urban dwellings, is avoided by a large portion of the women who live in apartment-houses, and the work of nursery maids, and others who take out young children, is proportionally decreased.

THE INFLUENCE OF ALCOHOL ON THE DIGESTIVE FUNCTIONS IN THE NORMAL AND IN THE PATHOLOGICAL STATE.

GLUZINSKI has recently undertaken a series of experiments on human subjects, to ascertain the influence of dilute alcohol on the stomachal digestion. He gave to fasting individuals, some of whom were healthy, and others of whom were suffering from digestive troubles, a certain quantity of coagulated albumen, with a definite proportion of alcohol. At certain periods of the digestion, he syphoned out the contents of the stomach for chemical analysis. He was thus able to follow the march of digestion in its several

stages. The results of his experiments are as follows:

Alcohol rapidly disappears from the stomach, leaving not a trace of its presence behind. The digestion, as influenced by alcohol, is divided into two phases in healthy individuals: The first phase is characterized by a marked retardation of the digestion of albuminoid matters, which, in fact, fail to undergo peptonization as long as any alcohol remains in the stomach. The second phase begins after the elimination of the alcohol. It presents an absolute contrast with the first, and makes up for the slowness of the first period by increased functional activity of the stomach, so that the digestion is terminated about the same time as when no alcohol has been ingested. In the first period, alcohol retards the pepsin digestion. On the other hand, it causes a certain degree of excitation of the glandular elements, which is followed, in the second period, by a more abundant secretion of hydrochloric acid. This excitation persists, even after the albuminous elements have disappeared from the stomach.

The first period, that of slowing of the digestion, is generally very short. Experiments, in fact, show that one hundred grammes of albumen, containing twenty-five per cent. of alcohol, have, in many instances, completely disappeared from the stomach at the end of fifteen minutes. The second period, during which digestion is accelerated, supervenes quite speedily.

The conclusion which Gluzinski draws from these experiments is that, in reality, the ingestion of small quantities of alcohol exercises a favorable influence on the digestion in individuals in good health.

In the pathological state, the two phases of digestion are much less marked after the absorption of a certain quantity of alcohol. The second period, that of excessive functional activity, is almost completely wanting in most persons. These facts show that in cases of dyspepsia (for example), physicians should not recommend, with the intent of promoting digestion, the usage of beverages which contain a large percentage of alcohol.

#### THE PASTEUR INSTITUTE.

We learn from recent French papers that the Society of the Pasteur Institute has declined — for reasons that do not sufficiently appear — the large lot of land offered for the erection of the new building by the Municipal Council of Paris. The Communal Assembly was the scene of an animated discussion on the 22d ult., when was presented the report of Georges Berry concerning a proposition of M. Cateaux, the purport of which was to stay the proceedings of the Council, relative to the concessions granted M. Pasteur. Some of the members present expressed quite freely their utter disbelief in the efficacy of Pasteur's anti-rabic inoculations, which were credited with numerous deaths, and congratulated the Council on being rid of a burden of responsibility. M. Navarre told the Assembly that in giving moral support to

Pasteur, the Council was recognizing the worth of a method whose scientific validity was every day being disproved, and he added with fearful sarcasm: "*S'il est des morts qu'il faut tuer, M. Pasteur n'est pas de ceux-là, car il s'est suicidé.*" (If there are more dead men to kill, Pasteur is not among them, for he has killed himself.)

Against this sentiment, the President and others present (notably M. Cochûn) vehemently protested, and assured the Council that the Committee of the Pasteur Institute had no intention of renouncing their humanitarian work whose general utility (despite some inevitable failures) had been sufficiently recognized. Pasteur would go on with his labors, perfecting them by new experiments and researches, and France was honored when its government aided the beneficent enterprises of its men of genius. In the meantime we learn on good authority that M. Pasteur is the subject of advanced nephritis, and is not likely to survive long to continue his labors.

#### MEDICAL NOTES.

— The following items from the *Hamburger Nachrichten* and *North German Allgemeine Zeitung* have been received from the United States consul at Hamburg:

"In consequence of the suspicious death which yesterday occurred at Pesth, bacteriological examinations have been made, which have shown that the person in question really did die of Asiatic cholera. Yesterday a fresh case is said to have been discovered."

"Constantinople, March 29th.—In consequence of cases of cholera at Pesth, a quarantine of five days has been ordered for products coming from the Danube and the Black Sea from the mouth of the Soolina to Boorghas."

— United States Consular reports from Catania state that eight cases of cholera and three deaths from that disease were registered during the week ending March 26th. The consul says that "the wells of the city (with few exceptions) have been closed by official order. Water has been brought to the city from the slopes of Etna in closed conduits. As soon as this water came into use the cholera began to disappear. During the past four days no cases or deaths have been reported. It is hoped that the malady has terminated. Application has been made to the government to have quarantine removed."

— Kanehiro Takaki, Medical Director General of the Imperial Japanese Navy, publishes in the *Sei-I Kwai Medical Journal*, April, 1887, a tabulated report of the patients suffering from kakke (beri-beri) in the navy, from 1878 to 1886. The following is the total number in each of these years, beginning with 1878. 1,485, 1,978, 1,725, 1,163, 1,929, 1,172, 661, 9, 3. The deaths during the same years were, respectively, 32, 57, 27, 30, 51, 49, 8, 0, 0. The enormous decrease in the cases of the disease during the last two years, is ascribed by the director-general to an improvement in the scale of diet made in April, 1884. He adds that even the few cases in the last two years were found after examination to have occurred among those who did not share the improvement in the food.

—The *New York Medical Journal* publishes an abstract from a book, giving the history of a journey to Saragossa, Barcelona, and Valencia, in the year 1585, by Philip II, of Spain, in which is contained an alleged instance of remarkable fecundity. The book was written by Henrique Cock, who accompanied Philip as his private secretary. On page 248, the following statements are to be found: "At the age of eleven years, Margarita Gonzalez, whose father was a Biscayan, and whose mother was French, was married to her first husband, who was forty years old. By him she had seventy-eight boys and seven girls. He died thirteen years after the marriage, and, after having remained a widow two years, the woman married again. By her second husband, Thomas Ochoa, she had sixty-six boys and seven girls. These children were all born in Valencia, between the fifteenth and thirty-fifth years of the mother's age, and at the time when the account was written she was thirty-five years old, and pregnant again. Of the children, forty-seven by the first husband, and fifty-two by the second were baptized; the other births were still or premature. There were thirty-three confinements in all.

—The London correspondent of the *Philadelphia Medical Times* writes that Mr. W. H. Power, one of the medical inspectors for the Local Government Board, seems to have shown, that, in some way not easy to understand, a small-pox hospital in a town causes a greater incidence of small-pox in its immediate neighborhood. He has taken the statistics for a great many hospitals, and has written a number of reports to his Board on the subject. One of the most recent relates to the small-pox hospital at West Ham. He found that within an area contained by a circle described three-quarters of a mile from the hospital, the death-rate from small-pox was much higher than in other parts of the same districts. It was never less than twice, and had risen to ten times, the general rate. Mr. Power has also given statistics which tend to show that the number of cases shows a progressive decrease on passing from the immediate neighborhood of the hospital in every direction. No explanation has yet been afforded of the influence of the hospitals. It seems to be independent of the winds, and the explanation at first suggested — that it was due to clandestine or accidental communication between the hospital inmates and attendants and the neighbors — is now found to be inadequate.

#### BOSTON AND NEW ENGLAND.

—A prominent dealer in spring waters in Boston, has lately placed before the medical profession and the public a new mineral water, which he claims, in staring capitals, is especially beneficial in cases of *DIABETIS*.

—*Essex North Medical Society.* At the annual meeting, held at the Franklin House, in Lawrence, May 4, 1887, the following officers were elected for the ensuing year. President, E. P. Hurd, of Newburyport; Vice-President, C. G. Carleton, of Lawrence; Secretary and Treasurer, M. D. Clarke, of

Haverhill; Corresponding Secretary, Aug. Stabler, of Lawrence; Censors: John Crowell, F. B. Flanders, J. F. Young, R. C. Huse, A. F. Shea; Councillors: H. J. Cushing, F. A. Howe, George Montgomery, F. H. Allen, R. B. Root, C. N. Chamberlain, O. H. Johnston, L. A. Woodbury, H. M. Chase; Commissioner on Trials: F. A. Howe, of Newburyport; Nominating Committee: C. N. Chamberlain, of Lawrence. The Censors reported the following doctors admitted as members of the Society: Franklin B. Pierce, of Methuen, Susan Elizabeth Crocker, of Lawrence, Joseph G. Burque, of Haverhill.

—*Norfolk South District Medical Society.* The annual meeting of the Norfolk South District Medical Society took place at the Robertson House, Quincy, May 4, 1887. The following officers were elected: President, Dr. J. H. Robbins, of Hingham; Vice-President, Dr. C. A. Dorr, of Hingham; Secretary and Treasurer, Dr. John F. Welch, of Quincy; Librarian, Dr. F. C. Granger, of Randolph; Commissioner of Trials, Dr. C. E. Prior, of Holbrook; Censors, Drs. J. C. Fraser, of East Weymouth, C. E. Prior, of Holbrook, S. M. Donovan, of Quincy, C. C. Tower, of South Weymouth, and G. W. Tinkham, of Weymouth; Councillors, Drs. J. A. Gordon, of Quincy, J. W. Spooner, of Hingham, and F. C. Granger, of Randolph; Nominating Councillor, Dr. J. A. Gordon, of Quincy.

#### NEW YORK.

—The commencement exercises of the Mount Sinai Hospital Training School for Nurses were held at the nurses' building near the Hospital, on the 5th of May. Two of the graduates read essays, and addresses were made by Ex-Governor Hoadley, of Ohio, and Dr. Heineman; after which refreshments were served and a social reception held.

—While during the weeks ending April 16th and 23d, only four cases of small-pox a week are reported, and during that ending April 30th, five cases; since then a considerably increased number have been met with by the authorities. One of these was in a German immigrant who was taken with the disease during the voyage to this country and who died while being removed from quarantine to the small-pox hospital on North Brother Island.

—The annual commencement of the college of Physicians and Surgeons is announced to take place at Steinway Hall on Wednesday evening, May 12th, when the address to the graduating class is to be made by the Hon. Stewart L. Woodford.

#### Miscellany.

#### ELECTRICITY IN THE TREATMENT OF TEDI- OUS LABOR AND POST-PARTUM HÆMOR- RHAGE.

A CASE reported by Dr. Guice de Fayette, (*Arch. de Tocologie*, February 28, 1887, and *London Medical Record*, April 15th,) is as follows: The patient was a

primipara, twenty-three years of age. Twelve days before labor came on, Dr. de Fayette was engaged to attend her, and on examining her urine, he found it contained a large quantity of albumen. When labor commenced, her face was oedematous, pulse 110. Head presented in the first position. The *os uteri* was at first rigid, but gave way after a dose of two grammes of chloral-hydrate. Uterine contraction was feeble and ineffectual. After working twelve hours, a strong and rapidly interrupted current of electricity was brought to bear on the inert uterus. When the head came down on to the perineum, the current was stopped. After delivery, as the uterus did not contract well, a dose of ergot was given. About an hour later the doctor was called hurriedly upstairs and found his patient flooding. He at once passed his hand into the uterus, but did not succeed in setting up contraction; he then removed the clots and injected vinegar, but still no effectual contraction took place. The injection of hot water was equally in vain. The battery was then called into requisition, and with the positive electrode in the patient's hand, and the doctor holding the negative electrode in his left hand, he grasped the flaccid uterus through the abdominal walls with his right hand; the effect was instantaneous, the uterus at once becoming powerfully contracted and the hæmorrhage ceased. After a few minutes the current was discontinued and the bleeding did not recur.

#### POISONING BY DRESSINGS OF SUBNITRATE OF BISMUTH.

THE *Paris Medical* of January 22d, and the *London Medical Record* of March 15th, contain notes of a case of poisoning after dressings of subnitrate of bismuth, described by M. P. Dalché, before the Société de Médecine Légale de France. A woman of thirty, in M. Peyrot's ward, was treated for two burns. One of these was of the third degree, and extended in length from the lower angle of the shoulder-blade to the gluteal region, and occupied the entire width of the back. The other was a large burn on the left arm. On September 26th these wounds were dressed with subnitrate of bismuth. The dressing, though renewed every second day, did not prevent them from becoming fetid. The general condition of the patient improved. On October 11th the throat became sore; there was dysphagia. There were pseudo-white membranes on the lower surface of the upper palate, the uvula, and the tonsils. On October 13th the patches had spread, the mucous above them was black, and the edge of the gums of the lower jaw was rough and dark-brown in color. There was a pseudo-white membrane, resting on a black spot of the mucous, on the lower lip. The general condition was good. There was no albumen in the urine. A few days later the breath became fetid, and there was gangrene of the upper palate. On the 26th the patches above described had partly disappeared, but there was a burning sensation under the tongue, and a series of black spots formed a track, upon which several pseudo-white membranes appeared. There were violent diarrhœa and continual vomiting; the gums and the patches on the buccal surface of the cheeks had a rough black edge. The bismuth dressing was abandoned. Up to November 1st, vomiting, diarrhœa, and hiccoughs per-

sisted. There was albumen in the urine. On November 5th there were pains along the œsophagus; a number of the patient's teeth were loosened; nevertheless there was slight improvement, which continued, and the patient completely recovered by the middle of December. M. Dalché is convinced that bismuth was the cause of the lesions observed, which were not the lesions peculiar to diphtheria, nor to any known stomatitis. The bismuth was pure; its presence was detected in the fecal matters and in the urine.

#### SYMMETRICAL GANGRENE (RAYNAUD'S DISEASE) FOLLOWING VARICELLA IN A CHILD, AGED FOUR, CAUSING DEATH ON THE FOURTH DAY.

MR. EDWARD BELLAMY reported an interesting case of this disease before a recent meeting of the Clinical Society of London (*Medical Press and Circular*, April 6, 1887): The patient was admitted under his care on January 19, 1887. On admission, she had spots of varicella over her body and face, which were first noticed on the 16th. On the evening of the 19th, at 7 o'clock, the child complained of her right leg being sore, and a small, circular, black patch, about as large as half-a-crown, was seen below the inner side of the knee. By 10 o'clock this patch had extended down the leg to the foot, when she was brought at once to the hospital. On arrival, a similar patch had made its appearance just above the left ankle, and which rapidly extended up to the knee. The patient was unable to stand, complained of great pain in both legs, and which increased on pressure. The second, third, and fourth toes of the right leg exempt from discoloration, and the fifth but slightly mottled. Shortly after admission, an oblong patch, about two inches by two inches, appeared on the outside of the left thigh. On the 21st, a small patch appeared on the outer side of the right forearm, and slight discoloration on either side of the spine, on a level with the crest of the ilium; in the afternoon of the same day, in either cheek and conjunctivæ of both ears. The complexion was very white, face sallow, expression dull and heavy, tongue dry and brown, but reddish at tip; pulse 150, weak; temperature 100°, heart-sounds normal; breathing normal, both legs cold and insensitive; pulsation, left femoral, fairly distinct, but could not be felt in right. Urine: specific gravity, 1023; clear, pale, no trace of albumen, and no hæmoglobin could be detected. In the evening of the 21st she became suddenly seized with stertor, and died. A full account of the post-mortem accompanies the paper. Among the most interesting points are the following: There was an enormous opening in the foramen ovale, bounded below by a valve one-fourth of an inch deep, having a free, crescentic margin. On dissection of the right leg, the fat and skin and gangrenous parts were dark purple, from hæmorrhagic infiltration, and this appearance died away at apex of Scarpa's space. The obvious gangrene ceased just above the inner condyle, the skin above being apparently normal. The legs appeared quite gangrenous, being uniformly purple. There were some petechiæ or small hæmorrhages in the intermuscular plane, the muscles themselves being very strongly contracted by rigor mortis, and appearing almost healthy, except where, here and there, they showed small hæmorrhages; this was especially the case in

the deeper fibres of the soleus. The femoral glands were a good deal enlarged, and either hemorrhagic, or containing a quantity of blood pigment. The saphena vein contained only post-mortem clot.

#### THE PROGNOSIS IN CASES OF HEART DISEASE.

In the *British Medical Journal* for February 12 and 19, 1887, Sir Andrew Clark reports a long series of cases of valvular diseases of the heart known to have existed over five years without causing serious symptoms, from a study of which he draws the following conclusions:

"*First.* That there are many persons with long-standing valvular disease of the heart engaged in the active business of life, who, without any symptom of heart disorder, have enjoyed good health, and have reached an advanced age.

"*Second.* That the mitral regurgitant murmurs so often encountered in chorea, for the most part disappear within eight or nine years of the attack.

"*Third.* That valvular inflammations, and their effects arising in the course of rheumatic fever, do sometimes disappear, and leave behind no clinical evidence of their former existence; and that this, occurring for the most part in the young, also occurs sometimes in the middle-aged.

"*Fourth.* That the signs of valvular defects arising out of the degenerative changes of middle life do, also, on rare occasions, disappear; and that, when circulatory and respiratory disturbances accompany their commencement, they sometimes subside, and permit of apparently complete readjustment.

"*Fifth.* That as there must be in the histories, habits, occupations, and surroundings of patients with valvular disease, conditions, which, in one case, bring about secondary disorders, and, in another case, exempt it from them, it is desirable that the respective *differential* should be discovered, and made capable of application to practice.

"*Sixth.* That any systematic and critical study of this subject likely to lead to practical issues could be undertaken only by the Collective Investigation Committee, and not by it unless actively assisted by experienced general practitioners, who possess, in a special manner, the knowledge necessary to the end in view.

"*Seventh.* That a joint inquiry of the kind proposed, conducted with due patience, discrimination, and accuracy, would greatly extend our knowledge of the natural history of diseases of the heart, and largely increase our means of assisting those who suffer from them."

#### JUVENILE INTERMITTENT ALBUMINURIA.

CONSIDERABLE interest attaches to cases of cyclical albuminuria, for their pathology is unknown, and, perhaps, is different in different cases. The causation of mere intermittency of symptoms generally has not received adequate attention. The *Lancet* gives the facts collected by M. Teissier in a fresh series of ten cases of cyclical albuminuria. He lays stress on the following features: A separation of oily matter on the urine, and the presence in it of brilliant bluish or metallic-looking spangles; the absence of true casts, though cylindroids, possibly of mucus, and sometimes drops of fat, may be detected with the microscope;

the slowness of the subjective symptoms, which may consist of mere vague feelings of malaise, of pain in the back, of weakness, or of pains in the limbs. Neuralgic troubles are rare. There is great nervous excitability or impressionability. Physical examination has never revealed the "bruit de galop." The lowness of arterial tension, which is calculated to be equal to a column of mercury sixteen to seventeen centimeters high, is important as an item in the differential diagnosis of cyclical albuminuria from interstitial nephritis. Dilatation of the stomach was observed in three cases. Three patients had had eczema or urticaria. Neither œdema nor "dead fingers" was noted. Speaking generally, the aspect of the patients is one of good health. The complaint, if such it can be called, is commonly curable; but slight relapses may recur under the influence of fatigue or violent impressions. The age that is most liable to the affection is ten years from puberty onwards; males suffer more than females. Violent exercise and excessive emotional excitement are direct causes. Teissier does not accept the mechanical theory of Bar, nor the theory of disturbance of the glomerular circulation of Maguin. His own view, propounded two years ago at Grenoble, he now believes to be insufficient to explain all the phenomena. A slowing of the combustion of albumens will not explain the presence of fatty matters, or the increase of urea in the urine. His present position is to regard the malady as due to over-action of the liver, which is the factor for urea, uric acid, and fatty matters. In treatment, the importance of hygiene is very great. These patients are, perhaps, predestined to become gouty. Shampooing, plenty of fresh air, prohibition of alcohol and white wines, and moderate exercise, are to be prescribed for these young men. Arsenic, inhalations of oxygen, cold baths, bromides and hydrotherapy, tannin, benzoate of soda, etc., are recommended, but especially sweet spirits of nitre, twelve to fifteen drops a day (alcool nitrique). Milk, eggs, and ham may be eaten, but not fish; thermal waters are good.

#### CAFFEINE AS A DIURETIC.

W. v. SCHROEDER, of Strasburg, has carried out a series of careful experiments, originally published in the *Arch. f. exp. Path. u. Pharm.*, Vol. XXII, 1886, and contained in the *Practitioner*, March, 1887, on the action of caffeine as a diuretic, using rabbits mainly, and also a few pigeons. His method was to tie a canula in one or both ureters, to collect the urine before and after administration of the drug, and to compare it with that of a probably normal animal, in quantity and quality. The first experiments were performed under the influence of morphine; but soon the results became inconstant, and in the later cases, even negative, the reflex excitability of the animal having greatly increased. He therefore had recourse to chloral, which deadened the nervous system more completely, and under which the flow of urine, though increased from the normal, remained practically constant. He obtained the same results by narcotizing with morphine, and cutting the renal nerves. After the administration of chloral, .02 gramme of caffeine in solution was injected into the jugular vein of the rabbit; and in the course of ten to fifteen minutes the flow of urine increased considerably, and continued so, more or less, for a period of from two to three hours.

On an average, the volume increased to about ten times the normal, and the solids three times, the nitrogen being correspondingly increased. Similar results were obtained from a few experiments carried out in the same manner on the pigeon. Caffeine itself causes a fall of the general blood-pressure, and in this way, influences to a slight extent the secretion of urine. However, after eliminating the central nervous system, either by section of the renal nerves, or the administration of a full dose of chloral, the effect of caffeine on the flow of urine is very striking. This leads him to conclude that its chief, if not its entire, effect is local, and he compares its action with that of pilocarpine on the salivary glands, except that it does not act through the medium of secretory nerves, but directly on the kidney substance. Whether the action is on the glomeruli or on the convoluted tubules is not clear, but he inclines to the view that caffeine is a direct stimulator of the renal epithelium. The complaint of the uncertainty of the action of caffeine as a diuretic is, he believes, due to its effect on the central nervous system, coinciding with the results of his first experiments, and referable to different susceptibility of the nervous system in different individuals. He therefore recommends the use, with caffeine, of some substance which may depress the nervous system, and he finds that paraldehyde serves the purpose very well. From his investigations, Von Schroeder concludes that caffeine acts in two ways: First, by exciting the central nervous system comparably to strychnine, which interferes with the secretion of urine; and secondly, by acting directly on the kidney substance, this effect being characterized by the occurrence of a free flow of urine.

## OBITUARY.

G. P. PRATT, M.D.

At the annual meeting, at Quincy, of the Norfolk South District Medical Society, the following resolutions were adopted, *apropos* the death of Dr. Gustavus Percival Pratt, of Cohasset, which took place April 29th:

*Whereas*, It has pleased an all-wise Providence to cause us to mourn the death of Dr. Gustavus P. Pratt, a worthy and much respected member of this Society.

*Resolved*, That we, members of said Society, do hereby tender to his bereaved family our heartfelt sympathy in their great affliction:

That we express to his numerous patrons our sorrow for the death of their loved and honored physician:

And that we condole with the people of Cohasset, in their loss of a prominent and valued citizen.

E. T. CASWELL, M.D.

At the meeting of the Staff of the Rhode Island Hospital, held on the 4th inst., the following was presented:

The surgeons and physicians of the Rhode Island Hospital, fully impressed with the great loss which they have suffered in the death of their late colleague and president, Edward Thompson Caswell, M.D., desire to express their recognition and appreciation of his marked ability as a man and physician.

Associated with the hospital from its very beginning his fidelity to its interests and his conscientious devotion to its exacting and time-consuming duties—even long after his health and strength had been sadly undermined by disease—commands our sincere admiration and respect and present characteristic qualities that awaken our endeavors to follow and emulate.

His long-continued and thorough medical education, his extended experience and high sense of professional honor, all combined to make his death, in the prime of life, a very great loss, not only to the hospital and the patients in its wards, but to each of his colleagues and to the profession that he adorned.

*Resolved*, That the Secretary be instructed to enter these resolutions upon the records of the Staff Association, transmit a copy to the family of the deceased, to the Journals for publication and to the Board of Trustees.

J. W. C. ELY, M.D., President, pro tem.,  
J. W. MITCHELL, M.D., Secretary, } Committee.

## Correspondence.

## BERI-BERI AGAIN BROUGHT TO NEW YORK.

BOSTON, May 9, 1887.

MR. EDITOR,—The enclosed cutting from a New York paper, kindly sent me by Dr. E. N. Whittier, speaks for itself. Beri-beri is again landed on our shores and again breaks out more than two months after leaving a country where the disease is endemic.<sup>1</sup>

Yours truly,  
FREDERICK C. SHATTUCK, M.D.

*Terrible Suffering of a Ship's Crew.*—New York, May 7.—The ship "Albana," from Manila, arrived to-day. She left Manila 119 days ago and out of a crew of nineteen able-bodied men, only six were able to work when she came into port. When seventy-five days out, the crew began complaining of pains in their legs, followed by peculiar swellings which soon rendered the majority unfit for work.

## LETTERS FROM DR. GEORGE HAYWARD RELATING TO THE INTRODUCTION OF SULPHURIC ETHER.

The following extracts are from two letters, written by Dr. George Hayward, at the time of the introduction of sulphuric ether, which were recently deposited with the Boston Medical Library Association, by Dr. Benjamin Cushing, to whom they were originally addressed in Paris.

BOSTON, January 30, 1847.

... There have been quite a number of operations at the hospital this winter, and all the patients operated on have thus far done well. Many of them have inhaled the vapor of sulphuric ether, and have thus been rendered totally insensible to pain during the operation. I have amputated a thigh, removed a breast, and done several other operations, almost equally severe, and the patients have suffered nothing at the time, and have had no ill effects afterwards. This is a wonderful discovery, and the credit of it belongs to Dr. C. T. Jackson, the chemist, and Dr. Morton, the dentist; Dr. Jackson suggested the use of the ether, and Dr. Morton made the first successful application of it. I see by the last journals that they are beginning to use it in London, and it will not be long before you will hear of it in Paris, if it be not there already.

We were the first to use it in surgical operations at our hospital (Massachusetts General) and I performed the first important operation, amputation of the thigh, in a patient under the influence of it. The effects in this case were so decided, that it was immediately used by others, and it is now employed to a great extent, not only by the dentists, but by surgeons. It is, however, violently opposed in Philadelphia, probably because it was not discovered there, and not first brought into use in the Pennsylvania Hospital.

FEBRUARY 28, 1847.

... I have taken a good deal of interest in the inhalation of the vapor of sulphuric ether to lessen the pain of surgical operations, and I am rejoiced to perceive that it has been so well received in Europe and so successfully used. I did the first important operations, on patients under the influence of it, that were ever performed. The first was the removal of a tumor from the arm of a woman, which took place at the hospital on the 17th of October, soon after my return, and on the 7th of November I amputated the thigh of a girl. Both patients were entirely insensible during the whole operation and both recovered rapidly without an unpleasant symptom.

These were the two first cases in which complete insensibility to pain was produced by the ether, except for the extraction of teeth. Since that time I have used it constantly, both at the hospital and in private practice,

<sup>1</sup> Journal, April 14, 1887.

with almost uniform success, and without any ill consequences in any case.

The article employed is nothing but pure sulphuric ether, and care should be taken that the lungs are well supplied with atmospheric air, so that asphyxia should not be produced, at the same time all the air that is taken into the lungs should be well charged with the vapor of the ether.

With regard to the discovery, there is no doubt that Dr. C. T. Jackson suggested its use to Dr. Morton to produce insensibility, but it is certain that Dr. Morton is the first who ever operated on patients, who were made insensible by the ether. He is a dentist and of course only used it for the extraction of teeth. After repeated successful experiments in dentistry, he requested that it might be used in more important operations at the hospital. This was done and the results were most satisfactory. I have stated this because Dr. Jackson has written to

France, claiming the whole merit of the discovery, taking no notice whatever of the part which Morton has had in it. I hope you will take some pains to let M. Velpeau and other surgeons know this. Morton, in my opinion, is entitled to great credit for the successful application of a suggestion of Dr. Jackson. All that the latter knew was, that persons could be rendered insensible for a time by the inhalation of sulphuric ether, but it remained for Dr. Morton to prove the all important point, that while in that state they could undergo surgical operations without pain.

I send you a copy of the *Medical Journal* containing Dr. H. J. Bigelow's account of the experiments with the ether, and I should be very glad if you would show it, as well as what I say about it in this letter, to my friend Mr. George Sumner (brother of Charles Sumner). I should be glad if he would take some pains to set the savans in Paris right upon the subject.

## REPORTED MORTALITY FOR THE WEEK ENDING APRIL 30, 1887.

Deaths reported 2,494; under five years of age 834; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fevers) 370, acute lung diseases 335, consumption 342, diphtheria and croup 145, measles 49, diarrheal diseases 43, scarlet fever 26, typhoid fever 26, malarial fever 23, whooping-cough 13, erysipelas 10, puerperal fever seven, cerebro-spinal meningitis six, small-pox (New York) two. From scarlet fever, New York 16, Brooklyn three, Boston and Pittsburgh two each, Philadelphia, Chelsea and Taunton one each. From typhoid fever, Boston nine, Philadelphia six, New York, District of Columbia, and Charleston, two each, Baltimore, Pittsburgh, Lowell, Salem and Brockton one each. From malarial fevers, Brooklyn nine, New York seven, Philadelphia, Baltimore and New Orleans, two each, Charleston one. From whooping-cough, New York four, Philadelphia three, Baltimore and Pittsburgh, two each, Brooklyn and Boston one each. From erysipelas, Brooklyn four, Philadelphia three, New York, Boston and Baltimore, one each. From puerperal fever, New York and Pittsburgh three each.

Charleston one. From cerebro-spinal meningitis, New York two, Richmond, New Orleans, Lowell and Malden one each. In the 18 cities and greater towns of Massachusetts, with a population of 876,014 (population of the State 1,942,141) the total death-rate for the week was 22.44 against 24.38 and 22.18 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,245,099, for the week ending April 16th, the death-rate was 20.9. Deaths reported 5,026; infants under one year of age 845; acute diseases of the respiratory organs (London) 363; measles 296, whooping-cough 115, scarlet fever 45, diphtheria 32, diarrhoea 26, fever 24.

The death-rates ranged from 10.6 in Bradford to 35.3 in Huddersfield; Birmingham 18.3; Bradford 19.5; Derby 17.8; Hull 19.9; Leeds 20.9; Leicester 21.5; Liverpool 25.3; London 19.8; Manchester 31.7; Newcastle-on-Tyne 22.9; Nottingham 21.9; Portsmouth 24.2; Sheffield 22.9; Sunderland 18.1.

In Edinburgh 18.4; Glasgow 27.4; Dublin 34.1.

The meteorological record for the week ending April 30, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.		Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 30, 1887, TO MAY 6, 1887.

FRYE, BLENOWE E., major and surgeon. Ordered for examination by Army Retiring Board, at San Francisco, Cal. S. O. 101, A. G. O., May 2, 1887.

BILLINGS, JOHN S., major and surgeon. Granted leave of absence for ten days, to take effect May 3, 1887. S. O. 98, A. G. O., April 28, 1887.

STERNBERG, GEORGE M., major and surgeon. Assigned by the President, to the special duty, under the Treasury Department of "investigating the merits of the method practised in Mexico and Brazil for preventing yellow fever by inoculation." Relieved from duty as attending surgeon and examiner of recruits in Baltimore, Md. S. O. 101, A. G. O., May 2, 1887.

MIDDLETON, J. V. D., major and surgeon. HAPPESETT, J. C. G., major and surgeon. AINSWORTH, F. C., captain and assistant surgeon. Appointed to assemble at U. S. Military Academy, West Point, N. Y., on June 1st, to examine as to the physical qualifications of the members of the graduating class and of the candidates for admission to the academy. S. O. 102, A. G. O., May 3, 1887.

LORING, LEONARD Y., captain and assistant surgeon. Sick leave of absence still further extended six months, on surgeon's certificate of disability. S. O. 103, A. G. O., May 4, 1887.

BRATT, VICTOR, captain and assistant surgeon. Sick leave still further extended one year on surgeon's certificate of disability. S. O. 99, A. G. O., April 29, 1887.

EWING, CHARLES B., first lieutenant and assistant surgeon. Ordered from Fort Leavenworth, Kan., to Fort Lewis, Colorado, for temporary duty. S. O. 100, A. G. O., April 30, 1887.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING MAY 7, 1887.

SHAFFER, JOSEPH, assistant surgeon. Detached from the "Minnesota," and to the "Ossipee."

SIMON, W. J., surgeon. Ordered to the United States Steamship "Boston."

HENRY, C. F., assistant surgeon. Detached from hospital, Philadelphia, and to the "Boston."

MEANS, VICTOR C. B., assistant surgeon. Detached from hospital, Mare Island, and to the hospital, New York.

SIMONS, MANLY H., passed assistant surgeon. Detached from Naval Academy and to the "Constellation."

DICHL, OLIVER, passed assistant surgeon. Detached from hospital, New York, and to the hospital at Philadelphia.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING MAY 7, 1887.

WYMAN, WALTER, surgeon. Detailed as chairman, Board for physical examination of candidates for appointment as cadet, Revenue Marine Service, May 6, 1887.

MEAD, F. W., passed assistant surgeon. Detailed as recorder, Board for physical examination of candidates for appointment as cadet, Revenue Marine Service, May 6, 1887.

#### SOCIETY NOTICE.

MEDICAL EDITORS' ASSOCIATION.—The next meeting of the Medical Editors' Association will be held in Chicago, on Monday evening preceding the meeting of the American Medical Association. The President, Dr. Shoemaker, will deliver an address, "Some of the Present Abuses of Medical Literature." It is desirable that all medical editors who can shall attend, as the organization is a permanent one and largely social. Dr. J. L. Gray, 70 Monroe Street, Chicago, is Chairman of the Committee of Arrangements. Members of the press who expect to be present should send their names as early as possible to the Secretary.

DR. WILLIAM PORTER,  
3137 Lucas Avenue, St. Louis.

#### DEATH.

Died in Boston May, 6, 1887, Marcus Bloomfield Leonard, M.D., M.M.S.S., aged sixty-six years, two months, ten days.

#### BOOKS AND PAMPHLETS RECEIVED.

THIRD ATTACK OF SCARLET FEVER. REMARKS UPON THE RECURRENCE OF ERUPTIVE DISEASES.<sup>1</sup>

BY JAMES B. AYER, M.D.

In December, 1879, Charlie U., at the age of five, was attacked with a severe form of scarlet fever. He was then living in Charlestown, and was attended by Dr. E. J. Forster. His mother tells me that she passed through two severe and undoubted attacks of scarlet fever, at the ages of five and seven, and that one of her brothers was twice treated for the same disease, at ages of ten and twelve.

**First Attack.** Dr. Forster recalls the illness, and says that it was complicated by a submaxillary abscess, and by perforation of both membrana tympani. Special attention was paid to the ears by Dr. Forster, and there was no subsequent deafness. Patient was not as robust after the disease. Subsequently, there is a reliable history of two attacks of measles, with an interval of three years between the attacks.

**Second Attack.** November 25, 1885, I was called to the patient, now eleven years old, for the first time, and found the body covered with a characteristic scarlet rash, which lasted three days, and was not accompanied by constitutional symptoms of any kind, nor followed by desquamation; but was repeated eight weeks later, January 25th, the rash again, lasting three days, and now being accompanied by decided fever, vomiting, pharyngitis, otitis pain, and discharge from the right ear, requiring treatment. Shortly after the subsidence of the rash there was a marked lamellar desquamation, involving the whole body. At the end of three weeks from the beginning of desquamation, there were still a few ragged shreds of cuticle upon the fingers and toes. The rash and desquamation were in every way characteristic of scarlet fever. Hardly had the house been disinfected, when, March 1st, the redness reappeared, again lasted three days, leaving, on the ninth day, a roughness of the skin. This was, I am informed, followed by desquamation. No constitutional symptoms attended the relapse, except a slight fever at the onset, but he was left in a debilitated state, and unable to attend school, partly on account of conjunctivitis and weakness of the ocular muscles of accommodation. After five months' vacation these symptoms disappeared and he returned to school in September, with restored health.

**Third Attack.** A month later, October 3, 1886, while passing Sunday in the suburbs, he complained of headache, and was brought home in a feverish condition. Next morning I found his body broken out with a pink rash, which, in a few hours, spread to the face. At first, I considered the rash of erythematous character (similar to the light-colored rash which generally accompanies his catarrhal colds), but in a few hours it became darker, punctated, and presenting the lobster-red appearance of scarlet fever, accompanied by pruritus and heat of the skin.

The temperature fluctuated between 102° and 101° when I saw him, each morning, but probably rose higher during the latter part of the day. On the fourth day, the fever, which had been high during the preceding night, fell as the rash began to fade, and there was a sudden

(oedematous?) swelling of the upper lip, which disappeared in eight hours.

On the third day, there was vomiting for the first and only time. There was otitis pain, severe enough to waken him from sleep several nights in succession. At times he complained of soreness in the throat in swallowing, but pharyngitis was slight, and there were no other symptoms calling attention to the mucous membrane, or to other organs of the body.

On the ninth day, while desquamation was going on, the rash reappeared for a few hours, during which time I saw him, and found his fauces reddened, and his temperature raised to 100°. Lamellar desquamation continued, and was in every way typical of scarlet fever. At the end of four weeks the body was smooth, but the fingers and toes were still peeling.

At the end of six weeks he was out of doors, and, with the exception of catarrhal colds, accompanied by an erythema of short duration, he has since been well. When I have examined him of late, I have found that his skin is dry, but otherwise normal.

I believe that the best modern authorities, as Thomas<sup>2</sup> and Bauze,<sup>3</sup> would agree in this

## SUMMARY OF THE CASE.

**First attack,** at age of five, severe, involving the skin, mucous membranes, glands, and membrana tympani.

**Second attack,** six years later: Typical skin eruption and desquamation; catarrhal symptoms present, but less marked. Relapse and sequelæ due to debility.

**Third attack,** seven months later: Skin as in second attack; mucous membranes slightly affected; pseudo-relapse. Though the mildest of the three attacks, it was too severe to be classed under the "rudimentary forms" of scarlet fever.

Although obliged to change my diagnosis after watching this attack forty-eight hours, I will repeat that I, at first, felt that the affection was of an erythematous character, known as "false scarlet fever."

The following is Hardy's description of "scarlatiniform erythema": "The eruption appears in the form of bright-red patches, resembling scarlet fever, which soon become darker. These patches are the seat of intense itching. At the end of twenty-four hours the rash disappears, leaving only slight desquamation. The eruption may be prolonged a little, and terminate in a considerable amount of desquamation, which rises in large, epidermic patches, like scarlet fever. The fever is slight or absent, tongue quite natural, throat only slightly reddened; it relapses very frequently."

M. Fercol reports a case in point, where desquamation was marked: "The patient, a young man, was seized with a scarlatiniform rash, following typhoid pneumonia. At the end of eighteen months the rash reappeared, followed by complete desquamation of the whole body. There was no fever. The pseudo-exanthema reproduced itself seven times during the year, always preceded by slight angina, with or without slight fever. The desquamation was always general, beginning in the upper part of the body, and ending in the feet; and, finally, the attacks become chronic and continuous."

Brocq, in the *Journal of Cutaneous and Venereal Diseases* (August, 1885), has an exhaustive paper upon the subject, "Desquamative Scarlatiniform Erythema," the most marked form of *false scarlet fever*, which dis-

<sup>1</sup> Read at the Boston Society for Medical Improvement, April 11, 1887.

<sup>2</sup> Ziemssen's *Cyclopædia*.

<sup>3</sup> Real-Encyclopædie der Gesamten Heilkunde.

ease is of extremely rare occurrence, and is noticed almost exclusively in adults. It is characterized by many symptoms in common with scarlet fever attacks, but has a less severe onset, is accompanied by less fever, and its rash is of longer duration. In short, all of these forms of "false" or "bastard" scarlet fever are evidently skin diseases—not constitutional affections—and not to be classed with the case I have reported.

Evidently, my case does not come under the head of any form of erysipelas or eczema, nor was it a rash due to surgical causes or to drugs, and it only remains to classify it under the head of repeated scarlet fever, provided that it is known that this exanthematous disease occurs more than once.

Formerly, the question, "Does one attack of scarlet fever secure subsequent immunity?" was answered in the affirmative.

In Dr. Copland's Dictionary we read: "Dr. Willan and many others prove the impossibility of a second attack of scarlet fever," but this statement is immediately contradicted by the admission: "There are exceptions to this law, perhaps one in two thousand or three thousand."

Bauze says: "Reliable authorities report a second, and even more attacks, in the same individual."

Thomas collected reports of two hundred cases of a second infection, besides a few of a third, fourth, and even more infections, in the same patient. He quotes Richardson as having experienced scarlet fever three times in his own person, and mentions a case reported by Sir Gilbert Blane, of a young lady who had three undoubted attacks.

William Squire<sup>4</sup> says: "Some persons have two or three attacks, or are liable to scarlet fever whenever they come in contact with it." As high a proportion of recurrence as six per cent. has been reported on good authority. As all careful observers agree with Trousseau that scarlet fever is more variable than any other of the contagious, exanthematous fevers, and as it would be difficult to classify together the severe and the mild forms of the disease, were it not for the fact that they may be equally contagious, it seems to me that there is a much greater danger of overlooking scarlet fever than of mistaking an erythematous rash for it.

There are many interesting points connected with this case:

**Prodromal Rash.** Whether the rash of three days' duration, preceding the second attack, was of erythematous or exanthematous character, cannot be definitely settled, but prodromal rashes may occur. Recently, I reported to this Society the case of a girl, ten years of age, whom I isolated on suspicion of scarlet fever, but dismissed her at the end of five days (when the rash disappeared), with a diagnosis of erythema. Three days later vomiting appeared, quickly followed by a typical attack of scarlet fever.

**Pseudo-Relapse** illustrated in our patient's third attack, when, on the tenth day of the disease, and fifth of desquamation, the rash reappeared for a few hours, accompanied by slight constitutional symptoms.

**True-Relapses** shown in the second attack by rash and desquamation, recurring soon after the disinfection of the house.

**Family Predisposition to Recurrence.** Murchison observed relapses of scarlet fever in two sisters. Triansky was able to establish the fact that, in two of

<sup>4</sup> Quain's Dictionary.

his cases of secondary scarlet fever, both parents had the disease twice, and in a third case, that, at least, the father had been affected twice. It is probably the rule that relapses and repeated attacks are less severe and less typical in character, yet this is not always the case.

#### REMARKS UPON REPEATED ATTACKS OF MEASLES.

The statement of most of the older writers, that susceptibility to measles was destroyed by one attack, has been disproved, and all modern authors agree that the disease has occurred two or three times in the same patient. Atkinson argues that it is illogical to insist upon a diagnosis of *rötheln*, in a doubtful case, solely because the patient has passed through one attack of measles, but has no doubt that many attacks of *rötheln* have been mistaken for measles. An accurate, differential diagnosis between measles and *rötheln* cannot be made. In illustration, I can relate a recent case:

A month ago, I found in my office a young man, twenty-one years of age, whom I had attended twenty-six months before for an undoubted attack of measles. Two days previously his eyes became inflamed, and he woke the following morning, early, with a chill and nausea. He attended to business in the forenoon, was feverish, complained of lassitude, and passed a poor night. When I saw him, the eyes were reddened and the lids greatly swollen, and there was a marked nasal catarrh and a dark-red dotting of the fauces. There was cutaneous hyperæmia of the cheeks, and small, mulberry patches, irregularly round and oval, about the ears and neck. On the body there was a measles-like rash, which was not confluent. During the following four evenings, the temperature rose from one degree to a degree-and-a-half above the normal. The pharyngitis became more marked about the fourth day, when the rash began to fade from the neck and body. The glands of the neck were not painful, and certainly not swollen to any extent.

When the blotches had disappeared and the rash had faded, there still remained the congestion of the cheeks and a pale marbling of the body, which are both natural to him in a state of health.

The mildness of the symptoms, and the short period of invasion suggested *rötheln*, but the catarrhal symptoms, and possibly the rash, favored the diagnosis of measles. The patient himself felt that his symptoms were similar to his first attack of measles, though of much milder form, and I felt it important to disinfect my office (as he had been waiting an hour), and to consider it a case of measles.

I believe that second attacks of measles generally are of a mild form, though it is stated that fatal second attacks occurred among Confederate soldiers in the early part of the late war.

**Varicella.** Curschmann states that this disease has recurred as often as five or six times. He says that while the second attack is generally mild, there are exceptions to the rule, as in the case of Louis XV, of France, who, after passing through an attack of variola in his fourteenth year, died of the same disease in his sixty-fourth. The experience of some physicians in this city, who have seen much of variola, confirms the belief that repeated attacks are not of rare occurrence.

**Varicella.** Thomas says: "A true relapse, that is, a renewed appearance in its totality, as reported by

Cassowitz, I have never seen." According to Trouseau and Canstatt, relapses of varicella are frequent.

*Syphilis.* There are unquestionable instances of second infection. Dr. Jonathan Hutchinson says that, while twenty-five years ago it was taught almost universally that one attack secures immunity from others, he himself has had not a few opportunities for observing the course of second attacks in patients whom he had seen during the first attack. These second attacks, he said, were generally modified.

Bamber asserts that a second attack of the disease will be a modified one, and will be milder the earlier it takes place after the first.

*Erysipelas.* This is a recurrent disease. Pich, in "Heath's Dictionary," says: "A patient who has been once attacked by this disease is more prone to have it again than one who has never suffered—a marked contrast to the diseases we have been considering, where one attack generally confers immunity."

#### A CASE OF LABOR AT EIGHT MONTHS: SHOULDER PRESENTATION, VERSION; ADHERENT PLACENTA. CHILD WITH IMPERFORATE RECTUM: OPERATION, RECOVERY.

BY GEORGE G. HAYWARD, M.D.

Mrs. T., a young and rather delicate woman, under my care for her second gestation. This she was very anxious about, as the first had terminated unfavorably with a miscarriage at about the fifth month, brought about by fright. She became pregnant for the second time in the latter part of May (catamenia ceasing about the 25th, bringing the expected confinement early in March. Her general health had been very good throughout gestation, and she was able to take a proper amount of exercise, and showed her condition very little.

January 24th she was thrown from a sleigh, and not feeling any injury at the time, insisted upon walking home.

Two days later I was called, and found she had been talking the matter over with her friends, and had become very nervous. Rest was enjoined, and small doses of bromide of sodium given at night. No ill results followed, and she was soon able to be about again.

February 4th, she fell upon the sidewalk, and three days later began flowing slightly; this was increased upon movement. Rest was again enjoined, with careful watching, the flowing soon ceased.

February 11th, about noon she began to feel pains in the lower part of the abdomen, and was at first inclined to attribute them to the bowels. In fact, she had a movement of the bowels at about this time. But as the pains continued growing stronger and more frequent, she began to realize that it was probably something more serious. I was not called until about eight in the evening. Pains were at that time every ten to fifteen minutes, and not severe.

Abdominal and vaginal examination combined, revealed the following state of affairs, namely:

A small child, placed obliquely, with its head in mother's left iliac fossa, breech at fundus to the right, back anterior, membranes intact, os admitting two fingers, right shoulder presenting at the brim. Present-

ing part freely movable between the pains. Fetal heart 150, regular.

The patient was now placed upon the left side, with the hope of inducing the head to engage. This, however, failed, and at nine, P.M., the condition of things was not materially altered. The os at that time would admit three fingers. The arm and shoulder presenting.

Fearing that the membranes would soon rupture, rendering version more difficult, and that the arm might be forced down, podalic version was at once determined upon (Braxton Hicks method).

Accordingly, the bladder and rectum having been previously emptied, and a vaginal injection of 1-3000 sublimate given, ether was administered, and the patient brought to the edge of the bed, in the left lateral position, thinking that this would rather facilitate the version. The right hand was introduced into the vagina, antiseptic precautions being fully observed. Three and finally four fingers were introduced within the os, and by so doing raising the presenting part somewhat, and passing behind it. The membranes were ruptured as high as possible, and by the combined method both feet were easily secured, and brought well down into the vagina. The dorsal position was then assumed, and uterine contractions soon followed, and with them came the breech and body, (dorsum anterior). No traction was used.

The arms were easily freed in the ordinary manner. External rotation was complete, the occiput came to the arch, and the head quickly descended into the inferior strait. Here some little difficulty was experienced in flexing the head, owing to the rigidity of the perineum.

The pulsation in the cord up to this time had been good, but it now ceased. Perhaps a minute was lost before extraction by (Smellie's method) could be effected. 9.30 P.M. Preparations for forceps, on the aftercoming head, were made, and had the latter failed, would have been resorted to. The child (female) was asphyxiated. The mucus was expelled from the mouth and nostrils, artificial respiration, blowing in the child's mouth plunging it in hot and cold water alternately, and all the various methods were tried, during the half-hour spent in resuscitating it. The child was then wrapt in a warm blanket and cotton-wool, and placed in a deep basket over the steam-heater. Hot-water bottles were placed at the child's feet and body. And a very even, warm temperature was thus maintained.

On returning to the patient, the placenta was found to be firmly adherent, antiseptic precautions were again taken, and the right hand following the cord was passed up into the uterus, to the attachment of the placenta, which was found to occupy the upper uterine segment a little to the left side. The placenta was carefully detached and brought down at 10.20 P.M.

A vaginal injection 1-3000 sublimate was then given, and two drachms of the fluid extract of ergot, administered. The uterus contracted well, and remained so, and there was very little hemorrhage. The antiseptic method being used the binder and pad were then applied. A little later the patient was given some warm beef tea, and she soon dozed off into a refreshing sleep. An uninterrupted convalescence followed, the temperature never rising above 98.8° nor the pulse above 80.

The milk appeared on the third day, but was thin and watery, and the child refused it. Nursing was

\* Read, by invitation, before the Obstetrical Society of Boston, March 12, 1887.

abandoned, and the breasts were supported and rubbed.

February 12th, the day following the birth, an attempt was made to give the child some little nourishment. Breast milk and goat's were both tried, and rejected, nothing was retained. Later in the day, as no urine or meconium had been passed, an examination was made, and the child was found to have an imperforate rectum. The orifice of the anus was present, and through this the probe passed into a cul-de-sac, the depth of three-quarters of an inch.

Examining still farther, the urethra was not to be found. Dr. Porter was called in consultation, and verified my diagnosis; he advised deferring any operative measures until the next day, and quoted a case in his own practice similar to this, where the urethra could not be found, and subsequently showed itself.

On the next day, February 13th, during my visit, the child passed water from the vaginal orifice. The operation was performed by Dr. Porter in the afternoon, the details of which were kindly given by him, and will appear later on. Three large dejections of meconium immediately followed, and three more during the next twelve hours. All food was retained after the operation, and no farther difficulty presented itself. The bowel was dilated occasionally, and for this purpose the ordinary glove-stretcher proved to be a most useful instrument.

Taking into consideration the development of the rectum in the fetus, it seemed to me more proper to

term this variety imperforate rectum, rather than imperforate anus. This view is supported by Holmes<sup>2</sup> and others.

"Cases of imperforate rectum may be divided into two classes, namely, those in which no anus exists, (imperforate anus, properly so-called), and those in which there is an anus leading into a cul-de-sac (imperforate rectum in the narrower sense of the term).

"The former class, (imperforate anus), may be again subdivided into (1) Membranous obstruction of the anus. (2) Complete or partial absence of the rectum. (3) Communication of the rectum with the vagina in the female. (4) Communications with the urinary tract in the male. (5) External communication, or fistula.

"The latter class (imperforate rectum) may be subdivided into (1) Membranous obstruction. (2) Deficiency of the upper portion of the rectum.

"We have now to consider the cases of imperforate rectum in the narrower sense of the term, that is, cases in which the external parts are normal, but the anus leads into a small cul-de-sac, the rectum being totally obstructed above.

"The obstruction of the rectum may be due to a simple membrane stretched across the tube of the intestine, which in other respects is natural; or the upper tube (the rectal cul-de-sac, as it is called), may lay by the side of the lower (the anal cul-de-sac), or behind it; or the rectum may be impervious for a greater or less distance, so that the colon may terminate by a dilated extremity above the pelvis. In rare cases the sigmoid flexure itself, and more or less of the rest of the large intestine, may be absent; but as such infants are usually not viable, the cases present little practical interest. Practically, cases of imperforate rectum may be divided, as above, into two classes, that is, (1) Where the upper cul-de-sac is accessible from the lower. (2) Where it is not.

## INJURIES TO THE BACK IN RAILROAD ACCIDENTS.<sup>1</sup>

BY E. P. GERRY, M.D., JAMAICA PLAIN, MASS.

In calling attention to this subject I am well aware that I can only give it an imperfect glance at this time. I shall divide my subject into topics; (1) The liability, in railroad accidents, of injury to the back. (2) The different ways a passenger may be injured. (3) Ways in which a passenger may perhaps prevent such injuries. (4) Some suggestions on transporting the injured. (5) Some of the injuries to the back received at the recent Roslindale accident. (6) Method of handling such patients in bed. (7) Difficulty of giving a correct prognosis as relates to damages.

(1) The liability and almost probability that a person will receive some injury to his back. To those who know and realize the conditions existing in any railroad accident, and especially that at Roslindale, the wonder is that more well-marked cases of injuries to the back have not presented themselves. The probability of such injuries is well known to the community at large, as are also the serious and sometimes permanent injuries received. The laity have become so impressed with this knowledge that the very heavy

<sup>1</sup> Read before the Norfolk District Medical Society, April 26, 1887.

<sup>2</sup> Holmes's Surgery, pp. 810 and 815.

damages awarded by juries for such injuries have made the expression "railroad spine" almost classical in our language as well as the *bête noir* of the companies themselves. To the injured, any injuries about back, hips or sides, render them fearful that something serious may develop even after years have elapsed. This possibility also opens a large field for the unscrupulous. From my knowledge of the persons injured near Roslindale, I should say that a large proportion received some injuries about the back, most of them probably temporary.

(2) That there are many ways in which a person may be injured, one may well imagine, when he thinks of what takes place, and in how many directions a person may be thrown, and with how many things he may come in contact. He may be thrown the length of the car, perhaps violently upon the floor or against the sides or the top, striking his back against the seats, or perhaps be pinned down by the *débris*. Two of my patients were sitting four seats from the front door, of course facing it. They think they jumped up when the alarm was given. When they came to themselves they found that they were up against the door facing the rear. Another, who was sitting next the rear door, on feeling the jar, rushed out upon the platform. He found his car tipping and saw that the smoking-car, which was behind, was coming upon him. He jumped and luckily escaped the smoker which came down near where he had fallen. His injuries were a comminuted fracture of the tibia and fibula, and a fracture of the astragalus, also a severe injury to the muscles of the lower back causing them to bunch up, resembling a Bologna sausage. The tendency is to jump up, as did another patient, who quickly crouched down in the aisle when he saw the top of the car sailing toward his head.

(3) It is very difficult to instruct a person what he had better do in case of a railroad accident. It is, however, highly important that some proper suggestions be given. It might be well to have an emergency lecture prepared in the most careful manner, and brought to the notice of the travelling public, so that the injuries received shall be reduced to a minimum. One cannot guard against missiles in the shape of flying beams, stoves and seats, but there should be certain simple rules impressed upon the minds of all, which they will act upon almost instinctively. It appears reasonable that if one can keep his place by clinging to his seat, he has the best chance, if nothing strikes him. I know of a case where a passenger was riding in the front part of a smoker. He was seated with his back square against the seat. He received no injury whatever from a rear collision that shook the passengers up and sprained one's back so that the patient laid abed two weeks. It is evident a square seat with the feet upon the rail is the best position to be in for an ordinary accident. One of my patients clung to her seat and although her car was carried into the street, she escaped with very little jarring and shock. The train hands usually have a better chance to see what is coming and may jump, but this is not considered good policy since the use of the Miller Patent platform and Westinghouse air-brake. An old rule among railroad men runs, "Don't jump till you can see the size of the gravel."

Perhaps it might be well to suggest to railroad authorities that the ordinary passenger coach should be provided with poles overhead similar to those seen in

some horse-cars, and such as are, or have been, in use in fast mail-trains, to which the clerks jump and catch hold, thus clearing themselves from the floor in case of derailment, as it is claimed that the trucks usually break up the floor; and then the passenger's attention should be called to the manner of using such poles. The clothing-racks should also be made strong enough to sustain a passenger's weight in case he wishes to use them for a similar purpose. The Roslindale disaster seems to demonstrate that the passengers fared best in the newer and stronger cars, as they usually do in the well-built Pullman. If this is true, railroad authorities should be constantly urged to build their cars as strong as possible consistent with other requirements.

(4) Next, regarding the transportation of the wounded, especially those with injured backs; I wish the good people in the vicinity of an accident, who grab their brandy bottles and rush to the scene, would also bring with them their strongest sheets. A patient could be carried on a sheet by men at the four corners or folded lengthwise and carried by two. It would be well to have the little seat at the end of the car fitted with a locker, containing among other things, narrow sheets, which in that case had better be of drilling or some strong material, and furnished with loops along the sides into which the poles before suggested could be run and thus an excellent stretcher made. Lay the wounded with their heads the highest, and keep them in that position all the time. When two men lift a wounded one, let the taller man be at the head, likewise when using a stretcher. Break step in marching with a wounded person on a stretcher. The cushions make temporary beds for the wounded, and the hair from the seat backs will do to pad up under injured parts.

(5) In speaking of some of the injuries to the back received, I shall include injuries to shoulders and those parts of the sides that are closely connected with the large muscles of the back. Although six of my eight patients received some injury to back or sides, it is confidently expected that all but two, and perhaps all but one, will completely recover. That there was considerable injury to the muscles in all the cases may be seen in the fact that although six weeks have elapsed, they all, with one or two exceptions, still are lame, some of them quite so, notwithstanding that the greatest care has been taken to keep them quiet. Luckily only one received injuries that resulted in serious and characteristic symptoms. Most of them were strains and contusions, somewhat severe, the result of being thrown violently several feet. They were in some cases not appreciated at first; one patient walked home, and then started for the doctor to visit his sisters, before he noticed any trouble himself. Some while they were in bed hardly realized that their back and sides were lame. Sitting up and walking about under careful supervision has in some cases made them much lamer. Some of them for the first ten days complained of chilliness and faintness, which did not appear to result from shock, but seemed to come from the injury to the back, not an unusual occurrence apparently in such cases. It was early ascertained in the patient who has undoubtedly serious injury that such was the case, although when first seen he was suffering from concussion of the brain, with snoring respiration, unconsciousness, etc. Some five or six of the vertebrae were injured, some of them

probably fractured about the cervico-dorsal portion, which is mentioned as one of the regions most frequently the seat of injury, there being two other portions equally liable, namely, the dorso-lumbar and the atlo-axial. The ribs attached to these vertebrae appeared dislocated, there was swelling and tenderness at this spot. Other symptoms were retention of urine, constipation and involuntary priapism when bed-clothes were raised. There was paraplegia, with loss of feeling in both legs, which has since continued, although there appears to be a slight return of feeling in one leg within a few days. In addition, there was a cystitis which was so active that the bladder had to be washed out twice a day for over a week. After the cystitis became better, the retention was followed by incontinence, which still persists. At the very first, there were bright-colored spots on both nates and lower back, which it was difficult to account for. It was thought they were bruises or burns, and they became dark-colored in a week or two, since then there have appeared on both legs similar spots with well-defined edges, whose centres are filled with red streaks. They are supposed to come from some defect of nervous influence due to some lesion of the spinal cord. There has been considerable pain in the back, a sensation of twitching of the muscles, and a feeling as if scissors were opening and shutting.

(6) One of the most important matters in the care of such a patient, is the careful handling which he requires and which in this case he has received from his nurse; who gives the following directions for lifting a person with an injured back: "Place a pillow under the shoulders and a draw or folded sheet under the back and hips, and if there is need a piece of rubber sheeting pinned by safety pins to the bed under the draw-sheet. To move patient to his right side cross the left foot over the right and the left arm across the chest; stand on the right side of the bed and pull the opposite ends of the draw-sheet and pillow slowly toward you, prop the back with pillows. To move him up on the pillows have assistance and lift with the draw-sheet and pillow; if alone, with the hands clasped under the shoulders. To move from one bed to another, place the empty bed lengthwise of the one occupied, and have four persons to lift at the four corners of the sheet, and the draw-sheet. Carry back in the same manner, and remove the soiled sheets which have been used in carrying him by turning him on his side and rolling the sheet lengthwise close to the body and remove by turning him on his back again. To make a good bed, place a comforter on the mattress, then a rubber sheet, then a bolster. Keep in place by pinning the under sheet on all sides to the mattress; over the middle of the bottom sheet place a piece of rubber sheeting, five feet long by three feet wide and over that the draw-sheet, as this is more easily changed than the under-sheet. By pinning securely to the bed with safety-pins wrinkles may be avoided."

(7) In speaking of damages, and the difficult position in which a physician is often placed in his endeavor to do his duty to all concerned, I am well aware of how perplexing a question I am bringing forward. Such questions have troubled many an honest surgeon, and there is little doubt but many a one's judgment in such matters has been questioned by some of his brethren in the profession. It would have been amusing, if it had not been fatiguing, to have answered the multitude of questions which have been asked by the friends

of patients relating to this point: many of them were of such a nature that in order not to be compromising to a physician's judgment, great deliberation would be necessary. In such an accident as that of the Buzzey bridge, it was especially difficult to give answers on account of the large varieties of injuries received. We would call especial attention, however, in this connection, to injuries of the back, for they are the ones that are particularly puzzling. The results of other injuries can usually be correctly prognosticated, but those of the back often render it almost impossible to form a correct judgment. This is often due to the fact that a physician cannot tell just what certain symptoms will lead to, and because he knows that what appears to be the most simple injury may in time develop into the most disastrous condition, in some cases many years after the original injury. It is this that makes railroad companies so fearful of what may develop from accidents, and the community as well is on the *qui vive*, for they feel that an appeal to the courts is often their surest way of gaining the largest damages. It is just here that the value of an honest and educated physician is clearly seen. There is a tendency among many to extract all they can from corporations who have injured them, and we believe that they should be paid every dollar that it is worth, as far as this is possible. It is known that they are often very successful in this, not only in this country but in England, for Mr. Bryant, of Guy's Hospital, told the writer that heavy damages were almost a foregone conclusion after railroad accidents, even if medical men almost demonstrated malingering. I will mention two kinds of malingers, those who carry it on with consummate skill for the purpose of getting as heavy damages as possible, and those who from nervous shock, and especially where the menstrual function is disturbed, or from the uncertainty attending settlement which permeates the homes of such patients even where they do not mean to allow it to influence them. There has been malingering, it is said, in persons who claimed damages for accidents which never happened in connection with the corporations from which such damages are claimed. It often requires the greatest wisdom to detect such imposters. Injuries to the back offer a wide field from the known uncertainty of their results. "Holmes' Surgery" says "that a broken back is known generally to be one of the gravest of accidents. The location of the injury must be considered, remembering that if it be below the level of the second lumbar vertebra, it may be expected that the patient, although the displacement is great, will retain motor power and sensation in his lower extremities and will recover. Should the fracture be through either of the vertebrae in which the terminal portion of the cord, surrounded by the roots of the nerves, is situated, the paraplegia may be partial; although complete the patient may have some hope of recovery. Fractures in the dorsal region are always unfavorable, but more so the higher the fracture to correspond with increased number of intercostal muscles thrown out of action in breathing; in fracture of cervical vertebrae, the surgeon counts only by days how long a patient will live." Such being the result of fractures to the vertebrae the surgeon will be called upon to determine if certain injuries will produce such symptoms as may be expected from hidden fracture or some injury which will not reveal itself for years. All must remember that the honest surgeon may be called

upon to act as a referee between the injured and the corporation at fault; that he will decide according to his best judgment what opinion he will give; that he belongs to neither party, but will see to it as far as his opinion is asked that the injured shall be paid according to their injuries; that he will not be a party to anything but the strictest honesty, and will conduct the business as he would his own, according to the strictest business principles.

## REPORT ON DISEASES OF CHILDREN.

BY T. M. BOTCH, M.D.

### PRIMARY NEPHRITIS IN INFANCY.<sup>1</sup>

THE importance of examining the urine in the early months of life in cases where, although the exact diagnosis of the organ affected is somewhat obscure, yet the group of symptoms representing the disease point elsewhere, rather than to the kidney, and the fact that very little is known about the clinical aspect of renal diseases in infants, in comparison with diseases of other organs, makes the investigations on this subject, by Dr. L. E. Holt, of more than ordinary interest.

Dr. Holt reports twenty-three cases of primary nephritis under the age of two years, and most of them under ten months. Of these, the diagnosis in nineteen cases was without much doubt correct, and in the remaining four probable. In all of these nineteen cases there seemed to be satisfactory evidence that they were independent of infectious diseases, and this opinion takes into consideration, also, the fact that scarlatinal nephritis not infrequently shows itself when the primary disease has been overlooked. Diphtheria, as a primary cause, was also carefully considered in each case. Eleven cases out of the nineteen died, and eight recovered. Autopsies were held in ten of the eleven fatal cases. In the single fatal case without an autopsy, the diagnosis rested principally on scanty urine, with an abundance of casts, a large amount of albumen, dropsy, and death in a comatose condition. In the eight cases of recovery, the diagnosis was made chiefly from the examination of the urine.

It is not to be supposed that the mortality here given of eleven cases out of nineteen represents the real death-rate from these forms of nephritis: the truth, no doubt, is that a great proportion of the milder cases escape notice altogether; and it is a significant fact, also, that in six of the fatal cases the diagnosis was not made until after the autopsy, and that, in most of these cases, the nervous symptoms had been the engrossing ones during life. This fact alone shows how easy it is for even careful diagnosticians to overlook cases of this class, and, no doubt, a large number of them pass under other names, even when fatal, unless autopsies are made.

The symptoms of acute primary nephritis, as a rule, are misleading, and tend to attract the attention to the brain or digestive system, rather than to the kidneys, the diagnosis only being made possible by repeated examinations of the urine, it being fair to say that the urine is seldom examined in infants under ten months of age, on account of the difficulty of obtaining a sufficient amount for analysis, and the possibility, also, of one specimen being comparatively free from abnormal constituents, while a second might show them to be in such abundance as to make the diagnosis quite clearly.

The catheter is, of course, the most reliable means for obtaining the urine for diagnostic purposes, and importance should not be attached to the presence of a few blood-globules, as these will almost always be found.

A study of the cases reported by different writers brings out the fact that acute nephritis in infancy may declare itself by unusual symptoms, and by an absence of symptoms which are usually considered to point towards renal disease. Thus, according to Dr. Holt, dropsy was not found to be a prominent symptom: it was noted in only five cases, and in one of these was not present till late in the disease. The quantity of urine passed is a symptom of which much is made in adult cases, and, when taken in connection with the specific gravity, it is very valuable for diagnosis. In infants, the difficulty in collecting the entire amount for the twenty-four hours' urine are very great, and it is especially significant that in only seven cases is it stated that the urine was so scanty as to attract attention. In five cases, the disease was ushered in by gastro-intestinal symptoms. Vomiting was present with more or less frequency throughout the disease in four cases. In six cases, some looseness of the bowels existed. Fever is mentioned in ten cases: in two cases the pyrexia was remarkably great, and in five cases it was high for a period varying from three days to four weeks. The pulse presented nothing of special interest. It was usually rapid with the high temperature, and weak only towards the close. The respiration was peculiar in five cases: in one there was very marked irregularity; in two it was very rapid, independently of high fever or pulmonary symptoms; in two more there was decided dyspnea: these symptoms were probably uramic. Nervous symptoms were prominent in almost every case; in several they engrossed the attention of the attendants. Convulsions were present in five cases, usually at the onset, or, more correctly, this was the first symptom noticed. This emphasizes the importance of the examination of the urine in every case of convulsions in children. An extreme degree of restlessness and irritability was seen in several other cases where convulsions seemed imminent, but did not occur. In some, high fever accompanied these symptoms, but in others they were independent of this influence. In three cases marked drowsiness existed, but in only one case was there complete coma.

The other nervous symptoms present were delirium, rigidity of the muscles of the neck, and irregular and contracted pupils. In two cases there was, from the very beginning, marked prostration, without variation in temperature or other striking symptoms; and, in one case, this, with the very rapid respiration, were the really only positive symptoms, and yet the case proved fatal in three days. The quantity of urine obtained for examination was nearly always so small, that but few observations upon the specific gravity could be made. Casts in abundance were present in nine cases. In three of these cases the urine was taken from the bladder *post-mortem*, a fact, which however, does not invalidate the significance of the casts. Casts were found in every instance, except one, in which a microscopical examination was stated to have been made, and in this case it was examined but once; but so small a quantity of urine was obtained, that the result could hardly be considered conclusive that they were not present. Albumen was present in large amount in thirteen cases: in four of these the urine was taken from the bladder *post-mortem*.

<sup>1</sup> Archiv. of Pediatrics, January, 1887.

[Delafield, from a large number of observations, has ceased to attach any importance to a small amount of post-mortem albumen, supposing that it comes from the epithelium of the bladder. The presence of casts, however, is as positive evidence in post-mortem urine as in that passed during life, and the same may be said of albumen, when present in large quantities.]

The following cases were of especial interest, and were patients of Dr. Holt's:

CASE I. Male, seven months old. Attack sudden, without apparent cause.

January 16, 1886. High fever and marked restlessness. Tubercular history on father's side. Temperature, at noon, 104° F., pulse 160, respirations 40. No evidence of disease in chest or elsewhere. Antipyrine, six grains in three doses, given within an hour. 5 p. m. Quiet and sleeping; temperature 101°. 9 p. m. Temperature 104.5°, and remained high, excepting when temporarily reduced by antipyrine, until death. The infant would strike his head, tear at his mouth, and throw himself violently about. The bowels were rather loose; no albumen found in urine. General appearance serious, but took breast well until June 20th. After that not so well, and sometimes not at all.

January 23d. For the first time, fine râles were heard on both sides of the chest, but no dulness or difficulty in breathing, the respirations being only 40. During the next two days the infant became drowsy, and the general symptoms indicated prostration. He became very pale, with, at times, cyanosis of face. Pulse rapid and thready; peripheral circulation poor. A marked cough now first appeared, January 25th.

On the thirteenth day, January 29th, decided cerebral symptoms were present: The abdomen was retracted, head thrown back, and neck rigid; pupils small, and responding sluggishly to light; respirations shallow, and, at times, irregular; drowsiness almost continuous; râles in lungs more abundant, but no evidence of consolidation; no vomiting, and bowels still loose. In the next four or five days, there were almost continuous automatic movements of the hands and feet.

February 4th. There was diminished resonance in both backs, and, for the first time, apex outside of the nipple, and systolic murmur loudest at base of heart. Urine, up to this time, passed freely. Now less free, with a specific gravity of 1013. Albumen in large amount; granular, hyaline, and epithelial casts numerous; pus and blood-cells. Died, comatose, February 7th.

The autopsy revealed nothing of primary pathological importance in the brain or its membranes (tubercle was carefully looked for), nor in the heart, liver, or spleen. There was broncho-pneumonia in the lungs, corresponding to the physical signs which developed four days before death, and which, evidently, was not the cause of the general symptoms which occurred early in, and during the sickness. The kidneys were nearly twice their normal size. Their weight, together, two and three-quarter ounces; consistency succulent. Capsule non-adherent; surface closely studded with yellowish masses, slightly raised above the surface, from a pin's head to a pea in size. A few small hemorrhages beneath the capsule. Between the yellow nodules the surface was of a grayish-white color, and there was general cloudy swelling. On section, the yellowish patches were found scattered through the organ, in some places following the line of the tubes, in others forming irregular masses in the cortex

and the columns of Bertini. The largest were a fourth of an inch in diameter, situated at the apex of the pyramids, and two or three contained creamy pus. Striations of urates in some of the tubes, and a few hemorrhagic spots completed the gross changes present. There was slight congestion of the pelvis, but no other abnormal appearances. The ureters, bladder, and testicles were perfectly healthy. Dr. Francis Delafield examined the specimen microscopically, and reported that it seemed to present the lesions of an acute interstitial nephritis, with the production of pus. The pus-cells were infiltrated in the stroma between the tubes, in small numbers in some places, in large numbers in others, but no abscesses, properly speaking, were seen. There were, also, changes in the tubes, necrosis of the epithelium, and cast matter. No bacteria were found.

CASE II. Male, seven months old. Healthy parents. Taken suddenly ill on Saturday evening, and died on the following Tuesday morning. The symptoms were crying, restlessness. Respirations sixty per minute; temperature never rose above 99° F.; pulse not especially frequent. Vomiting present in the beginning, but not severe, and did not continue; bowels regular. No cerebral symptoms, no paralysis, no convulsions; no physical signs of disease in the heart, lungs, or abdomen. The urine was passed moderately freely, and was examined once, with negative results. There were no positive symptoms, except a steadily-increasing weakness and rapid respirations. It died quietly and easily. The autopsy showed the organs to be anæmic, but otherwise normal, with the exception of the kidneys, which, microscopically, showed marked congestion, and, under the microscope, well-marked parenchymatous nephritis, with crystals of urates in the tubes and pelvis. The urine found in the bladder, on examination, contained so much albumen as almost to solidify on boiling, and numerous casts were seen under the microscope. It is worthy of mention that, during the last months of the infant's life, transient attacks of marked pallor were noticed while it was sleeping.

A third case, of a girl, three and one-half months old, was diagnosed as acute nephritis, and recovered. The history of the case is of a good deal of interest, and seems worthy of being reported: The infant was admitted to the New York Infant Asylum, August 17th, with pertussis, for which a two per cent. solution of resorcin was applied by a swab to the throat, five times a day.

September 23d. She was noticed to be very drowsy, sleeping much of the time, and the mother reported the child's urine to be green in color.

An examination, on September 25th, showed the urine to be olive-green, and give a decided reaction for albumen. The first marked elevation of temperature was noticed at this date (103° F.). The infant continued in the same dull, stupid condition, taking the breast poorly. The discharges were a little greenish, but not frequent, and there was no vomiting.

September 27th. Six ounces of urine were obtained, which contained a large amount of albumen. Hyaline and epithelial casts quite abundant; leucocytes and many uric-acid crystals; reaction strongly acid. The resorcin was discontinued, as being a possible factor in the disease, although, in fifteen or twenty other cases treated in this way, urine of this character had not been observed.

September 29th. Temperature rising irregularly to 101° or 102°, pulse rapid and weak, respiration, at

times, irregular, and always rapid. No enlargement of liver or spleen; albumen and uric acid as before, but no casts. There was very feeble breathing over the left upper lobe, and high-pitched, with a few râles. A diagnosis of pulmonary collapse was made, and stimulants, oxygen, and acetate of potash were given. The urine was thus kept alkaline, and the albumen became less, and the uric acid disappeared, the temperature also rarely reaching 101° F. Still, the pulse and respiration were frequently irregular, the abdomen was tympanitic, and the head was drawn back much of the time.

October 9th. The albumen was reduced to a mere trace, the nervous symptoms subsided, and the case went on to steady convalescence.

Dr. Holt states that chronic nephritis scarcely exists in infancy, but that the acute variety, especially in its lighter forms, is not rare, so that the urine should be examined in every case of convulsions, unusual prostration occurring in the course of other diseases, persistent vomiting, without apparent cause, in the stomach, rapid or irregular respiration, without any evidence of pulmonary disease, or sudden high temperature, without evidence of local disease.

#### INTERNAL SUPPURATION, WITHOUT FEVER.<sup>2</sup>

Dr. West reports a number of rare cases illustrating this point, and among them the following ones, occurring in children:

(1) *Suppurative Pericarditis*. Boy, aged sixteen. Pericardium twice tapped and laid open; complete recovery. Temperature, neither before or after the operation, was raised above the normal.

(2) *Suppurative Peritonitis*. Girl, aged ten years. Case very acute; abdomen opened, and foetid pus evacuated. Patient did not rally after operation, and the autopsy showed a primary peritonitis. Temperature not elevated throughout the disease.

(3) *Empyema*. Boy, thirteen years old. Case tapped twice, and twenty-four ounces removed; afterwards, ten ounces. The chest opened freely; recovery. No elevation of temperature at any time. In the last case, the pus formed very rapidly. Collapse was absent in all the cases.

#### SCARLET FEVER.<sup>3</sup>

Bokai<sup>4</sup> has discussed the various forms of inflammation of the joints occurring during the course of scarlet fever. He divides them into two classes, serous and purulent. In serous inflammation there may be either an acute or sub-acute and chronic course ending in white swelling of the joint, and in two cases the formation of pus was noticed. Two cases of purulent inflammation were noticed and were considered as symptomatic of pyæmia.

Julius Pollock<sup>5</sup> has published a case presenting unusual symptoms. Twenty days after the beginning of an attack of scarlet fever, there appeared swelling of the cervical glands and over the surface of the body a rash like a non-scaly psoriasis, which ultimately became dark in color. Acute cystitis supervened with swelling of the whole of the left leg below the knee, due to thrombosis of the femoral vein. The patient recovered completely.

Jabowitsch<sup>6</sup> has reviewed the present state of our knowledge as regards scarlatinal uræmia in children. Uræmic symptoms in his cases began either with a marked diminution in the amount of urine excreted, or with amblyopia and headache.

#### CEREBRO-SPINAL MENINGITIS.<sup>7</sup>

Under the name of cerebro-spinal meningitis, Henech describes a particular form of simple non-tuberculous meningitis which is of more frequent occurrence in childhood than is usually admitted. Its study is of the greatest importance from a diagnostic point of view, and its characteristic consists not only in its long duration but also in its alternate periods of improvement and deterioration, which leave the physician in suspense for a long time. The usual course of the disease is as follows: children who have been in apparent health are suddenly seized with high fever, which continues several days with morning remissions, with intense headache, vomiting, pain along the nucha and in rare cases contractures of the muscles of the extremities and cutaneous hyperæsthesia. At the end of about two weeks the fever ceases, the other symptoms disappear and everything seems to go on favorably with the exception that the pain in the nucha continues and indicates that the trouble still persists. After an interval of from one to several days, the fever reappears, the general condition becomes very bad and the pains in the head and nucha resume their original intensity. These remissions and exacerbations may be repeated several times in the course of the same week, leaving the physician in doubt as to the accuracy of his diagnosis. Tuberculous meningitis is taken into consideration, but after eight or ten weeks or even longer, the patient finally recovers. The true nature of the disease is not yet fully known. Treatment has no influence on its progress, and this point is particularly insisted upon by Henech, who has never seen a case terminate fatally. From the standpoint of pathological anatomy it would appear from the symptoms that the disease was one which involved the meninges of the brain, and, to a lesser degree, those of the spinal cord. The etiology of these cases is also very obscure, and their relation to epidemic cerebro-spinal meningitis not known. The latter disease may present the same symptoms, but it is believed that it would not be possible to consider all the cases, which present the phenomena described, as cases of infectious cerebro-spinal meningitis. The disease does not always follow this slow course. In connection with this paper, the author describes the "symptom of Kernig," which he has observed in several patients with meningitis; it consists in a contracture of the flexor muscles of the knee-joint while the thigh is flexed upon the pelvis.

#### PERIOD OF INFECTION IN CONTAGIOUS DISEASES.<sup>8</sup>

In connection with the investigations made by the British Medical Association, Ransome has reported the following data in a paper on this subject:

Measles was shown to be infectious in five cases before the appearance of the rash; in two cases at least two days before and in one three days before; in one also four days before the rash came out. Scarlet fever was communicated in four cases from twelve to twenty-four hours before the beginning of the rash.

<sup>6</sup> Charité Annalen, xi, 1886. Archiv. Podiat., April, 1887.

<sup>7</sup> British Med. Jour., January 29, 1887.

Mumps was conveyed in one case one day before the swelling of the gland appeared. Mumps was also found to be communicated by the patient two weeks after cessation of the fever, or three in all: measles thirty-one days after the invasion; scarlet fever four to seven weeks, longer in case of complication such as otitis, suppurating gland, etc. Diphtheria in one case was seen to be directly infectious after six weeks.

#### INCUBATION AND TRANSMISSION OF EPIDEMIC PAROTITIS.<sup>9</sup>

Three cases are reported by Dr. Roth<sup>10</sup> which aid in establishing the time of incubation and the manner of transmission of mumps: the period of incubation in all three cases was eighteen days. The first case was caused by actual contact, in the second the infectious material was apparently brought by the physician himself from a patient in the hospital to another patient in his home. In the third case the patient used the same bedding which had previously been used by a patient with parotitis.

### Reports of Societies.

#### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

APRIL 11, 1887, the President, DR. O. F. WADSWORTH, in the chair.

DR. JAMES B. AYER read a paper having for its title:

#### THIRD ATTACK OF SCARLET FEVER, WITH REMARKS ON THE RECURRENCE OF ERUPTIVE DISEASES.<sup>1</sup>

DR. C. E. STEDMAN asked if other inmates of the household were infected from this case, to which question Dr. Ayer replied that there were no unprotected members of the household. Dr. Stedman mentioned some patients who had an ill-defined eruption, resembling scarlet fever, and slight sore throat, there being a child in the neighborhood with scarlet fever. He could not feel sure about these cases, but had isolated them, and they might be second attacks. Every one knows that measles and röteln recur. He had known a baby to infect all the other children in a family with measles, and to have a second attack as the others were getting well.

DR. C. P. PUTNAM said that he had never happened to see a second attack of any one of the eruptive diseases. He, however, not only believes that they do recur, but he knows of a case, not his own, in which there had been a third attack of scarlet fever, with no possibility of question. He had, that day, seen a second attack of mumps. Although a second attack of whooping-cough is rare, he had met with a case of it in an adult, who was said to have had the disease as a child. The chief question of interest in this connection is not: why does the disease ever recur, but rather: why does it not always do so upon exposure. The first man who made up his mind that one attack commonly protects against another, was certainly a greater observer than he who first decided that second

attacks sometimes take place. We do not know more than the fact that one attack of certain diseases commonly, but not always, protects against a second. It is possible that the first attack commonly uses up all of the material in the system proper for the nutrition of a particular germ, but that sometimes some of it escapes.

DR. T. M. ROTCH remarked that, although the recurrence of scarlet fever is known to take place, yet this case of Dr. Ayer's is of unusual interest and rarity. He also said that while allowing that there was a distinct disease, röteln, he believed that the diagnosis of röteln was often made on insufficient evidence, owing to the symptomatology of the disease not yet having been clearly settled; different physicians enumerating different symptoms as diagnostic of röteln, where, on careful investigation, it seemed to him that these very symptoms had nothing to do with the disease röteln, but were simply occurring accidentally in the course of the special case.

DR. RUSSELL STURGIS mentioned cases reported at Philadelphia two years ago as röteln, in which there had been sore throat at night, without prodromal symptoms, and the next day a measles-like eruption. This was during an epidemic of measles.

DR. JAMES AYER mentioned a case which he had supposed to be one of röteln, the symptoms being unlike those of measles, although the eruption rather resembled it, the absence of fever being especially noted. This case occurred at a time when other men were reporting cases of röteln. He believes that the incubation period of röteln is longer than that of either scarlet fever or measles.

DR. PUTNAM said that the final test is the contagion of measles or scarlet fever from these attacks of röteln, for it is well known that the contagion from mild cases may give rise to severe ones. The diagnosis may be in doubt at first, yet he has had but two cases in which he could not make it at some stage, and he has never known röteln to give rise to either of the other diseases. He had seen cases in which the eruption was so like that of scarlet fever, that, judging from the eruption alone, he would not have been able to say that the child was not sick with scarlet fever; but there was no perceptible sore throat, and the rash disappeared on the second day, to be followed, after a period of exactly fourteen days, by an outbreak in the family of what was clearly röteln. The typical eruption of röteln has larger spots than that of measles. They are redder, flatter, and do not begin so decidedly on the face. If the eruption lasts over sixty hours, or better, say forty-eight hours, he should hesitate to call the case röteln. The incubation period is precisely two weeks.

DR. FRANCIS MINOT said that he was surprised that no one had called attention to a glandular swelling in the neck behind the ear as occurring very often in röteln.

DR. J. H. MCCOLLOM said in reply to a question, that he had seen three unquestionable cases of recurrent small-pox although second attacks are doubtless comparatively rare. One was an intelligent man of about forty-five; who twenty-five years before had had small-pox as was shown by his description of it, and also by his being marked. One was a woman of sixty who was not reported until the disease was well advanced. When she recovered, however, it was easy to distinguish between the old

<sup>1</sup> See page 465 of the Journal.

<sup>9</sup> Archiv. Pediat., April, 1887.

<sup>10</sup> Münchener Med. Wochenschr., 1886, No. 20.

pale pits and the new red ones. The third was a man who had had small-pox in infancy and who had a second attack a short time ago. It is reported in Aitken's practice that a certain physician always had fever and the characteristic eruption every time that he attended a case of small-pox.

Dr. McCollom expressed surprise at the remark of Thomas in "Ziemssen's Cyclopædia," that he had never seen an adult with varicella, and also at the remark by the same author, that the constitutional disturbance in most cases of this disease is comparatively slight. He said that he himself had seen a great number of cases of varicella in adults; and also that he had never seen a case of varicella, where there was not a greater or less amount of constitutional disturbance. In making the differential diagnosis we should never be guided by the severity of constitutional symptoms for a mild case of small-pox may be ushered in by very little constitutional disturbance, and, on the other hand, we may have a case of varicella in which there is headache, pain in the back, and a certain amount of nausea, which the authorities have taught us to believe is present only in cases of small-pox. The appearance of the eruption is the only thing upon which we can make a positive diagnosis.

He had seen four or five cases of measles in which the disease had recurred in two or three years. One was a child of two years, who had it very severely; and two years later had it moderately, this time communicating it to his brother and sister. He had never himself seen a second attack of scarlet fever, but thinks that there can be no doubt about Dr. Ayer's case, and believes that such cases happen more often than is generally supposed.

He had no doubt but that these diseases are more likely to recur during an epidemic.

Dr. STEDMAN spoke of the eruptive diseases of childhood as being milder in his experience than during the earlier years of his practice. Before 1870 he had met with greater mortality. He had then known of schools being closed because of the prevalence of these diseases. It is possible that in time, as the soil for them becomes less fresh, that they will be generally milder.

Dr. F. C. SHATTUCK said that ten years ago, when he had a dispensary district he saw a sufficient number of bad cases of scarlet fever such as now he did not encounter in a different class of persons. He then suggested that there are some reasons for thinking that this, in common with other infectious diseases which have existed for a long time, may have a gradual tendency to run out. There seems to be no doubt that syphilis is a much milder disease than it was formerly; it certainly does not appear in the virulent form which history tells us it assumed shortly after the discovery of America. The ravages which syphilis produced after its introduction into the Sandwich Islands, and the thirty thousand deaths which measles caused in the Fiji Islands not many years ago, suggest that civilized people, so called, gradually acquire a relative immunity against infectious diseases.

It does not seem far-fetched to suppose that the change in the organism, whatever it may be, which renders an individual insusceptible to a second attack of some particular disease, may, in the course of time, be transmitted in a measure to descendants, and result in a modified form of the disease. There can be no question that the treatment of infectious, and, indeed,

of all diseases, is, on the whole, much more rational than it was; and this factor must have its due weight.

Dr. JAMES AYER remembered that in making the diagnosis of chicken-pox, he had been in the habit of attaching great importance to the shape of the vesicle; which is often triangular or irregularly square, especially upon the back of the neck. He would like to have Dr. McCollom's opinion as to this point.

Dr. McCollom said that he thought it a valuable diagnostic mark, and he also alluded to the great difference in the size of vesicles in a given case of chicken-pox, and called attention to the fact that the vesicle of varicella can be very easily ruptured, and when ruptured, empties itself completely, or in other words, the vesicle of varicella is unilocular while that of small-pox is multilocular. One should bear in mind that in variola the deeper tissues of the skin, and in varicella, the more superficial are involved.

#### PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. M. GREEN, M.D., SECRETARY.

MARCH 12, 1887, the President, Dr. WILLIAM L. RICHARDSON, in the chair.

Dr. G. G. HAYWARD reported, by invitation,

**A CASE OF LABOR AT EIGHT MONTHS: SHOULDER PRESENTATION, VERSION: ADHERENT PLACENTA. CHILD WITH IMPERFORATE RECTUM: OPERATION, RECOVERY.<sup>1</sup>**

Dr. C. B. PORTER saw the infant first twenty-one hours after its birth; at that time no urine and no feces had been passed. The most careful examination with small flexible bougies failed to find the meatus. The anal orifice was present, but on passing a large probe was found to terminate about one inch above the orifice in a cul-de-sac. The bearing-down efforts of the child were very feeble, and operative measures were advised to be postponed for twenty-four hours, in the hope that the rectal cul-de-sac would become more prominent, and the bearing-down efforts more vigorous. The wisdom of this course was fully demonstrated on the following day when a second examination was made. In the meantime the child had passed urine. Stretching the anal cul-de-sac and watching carefully it was seen that there was at varying intervals a rather uncertain bulging which seemed as though it might be the rectal cul-de-sac pressed down by the straining of the child.

**Operation:** A sharp-pointed, small, grooved needle was pushed from the apex of the anal cul-de-sac upwards as near as possible towards the centre of the prominence of the superior cul-de-sac. No fluid followed, but the point of the needle moved about as though in a cavity. A pair of sharp-pointed scissors was run along the groove of the needle and the blades opened, when alongside of them the meconium very thick and tarry followed. The child had three discharges within a short time, each stimulated by the introduction of the little finger. Dr. Porter saw the child twice after the operation, and each time dilated the passage by the introduction of the little finger; but there was no marked tendency to contraction. The vomiting which had persisted up to the time of the operation was completely relieved.

<sup>1</sup> See page 467 of this number of the Journal.

The points tending to the successful issue in this case, which was unfavorable from the fact that it was an eight months' child, were:

*First:* The delay for expulsive efforts to become more vigorous, to give an indication as to the location of the rectal pouch.

*Second:* The use of a small, sharp, grooved needle, instead of a trocar or knife, which would penetrate more easily a pouch which was not fully distended and not forced downwards by violent, expulsive efforts as is sometimes the case.

*Third:* The use of sharp-pointed scissors instead of the knife, as thereby not a drop of blood was lost and the size of the rent in the upper cul-de-sac was made to exactly correspond with the one in the lower, which could not have been as accurately affected by the knife.

There is always more or less danger of subsequent cicatricial contraction; but the amount cannot be foretold, and in this case there has been so little that it is not probable that any trouble will result therefrom.

Dr. STRONG asked if colotomy could not be performed as a temporary expedient to relieve the child, and whether later the blind intestinal end would not pouch down, so as to be reached *per anum*.

Dr. PORTER replied, that inguinal colotomy might be performed for relief of the symptom of obstruction, but not with the hope that the rectal cul-de-sac would later become more prominent. But with an opening in the groin it might be possible to introduce a sound or some stiff instrument through the opening downwards into the rectal pouch and make it prominent in the region of the anal cul-de-sac, and thereby enable the surgeon to complete the artificial anus at that point and subsequently close the inguinal one.

Dr. SINCLAIR inquired if imperforate rectum was found more frequently in girls than in boys.

Dr. PORTER replied that he recalled at the moment only three cases in which he positively remembered the sex, and two of these were girls and one a boy. Dr. Porter subsequently contributed the following addition to his remarks on this subject:

In the catalogue of the Warren Museum the late Prof. J. B. S. Jackson makes this statement as the result of his examination and observation of post-mortem specimens of imperforate rectum and anus.

"In cases of imperforate anus, an opening into the 'bladder' or 'urethra' is occasionally reported; but so far as I have seen an opening into the membranous portion of the urethra is always found in an ordinary case of imperforate anus in the male subject. In extraordinary cases or where there is great malformation of the internal organs the opening may be into the fundus of the bladder, or there may be a great deficiency of the large intestine, and no opening at all. The opening is usually small but easily demonstrated, if the rectum is inflated under water."

"When the anus is imperforate in the female, the rectum opens into the vagina; and this opening seems to correspond to that in the male subject, the membranous portion of the urethra being the genital portion of the urinary canal."

In an analysis, by Mr. Curling, of one hundred cases of "Congenital Imperfections of the Rectum," with reference to an operation,<sup>2</sup> he gives twenty-six in which the intestine opened into the urethra or neck of

the bladder, and he remarks that there "were very probably more; as the opening is sometimes so minute as to prevent the free escape of meconium during life."

In an analysis of 104 cases of "Imperforate Anus and Rectum," by Dr. George H. Gay,<sup>3</sup> he states that there was an operation in 77 cases: cures 25; deaths 52.

Dr. GREEN had seen two cases of imperforate rectum in his Dispensary Obstetric Clinic. One case was in a boy, and there was a fistulous connection with either the bladder or the urethra. Dr. Beach operated on this case at the Massachusetts General Hospital and established an opening *per anum*; but the child died in thirty-six hours. The second case was in a girl, and was successfully operated on by Dr. Gay at the City Hospital: the infant passed feces easily for several days, and undoubtedly would have lived, with proper care; but it was neglected by the family and pined away.

Apart, however, from the presence and successful treatment of imperforate rectum, Dr. Hayward's case was one of great interest; not only as a triumph for antiseptic obstetrics, with speedy, non-febrile recovery after version and manual removal of an adherent placenta, but also on account of the successful care of a premature child.

The great desideratum in the care of the premature infant is the maintenance of bodily heat. This may often be accomplished by hot-water bottles and heaters; but the most effective apparatus is the hot-water cradle, or the convense of Tarnier. When these cannot be obtained, a very good substitute can be improvised by the use of two tin pans or foot-tubs of such relative size that one can be placed in the other and surrounded by hot water, as described by Worcester in his Manual on "Monthly Nursing," page 212.

Dr. W. L. RICHARDSON said the case seemed one of exceptional interest. The fact that the temperature during the convalescence never exceeded 99° bore testimony to the efficient manner in which the antiseptic method of treating such cases had been carried out. He agreed with Dr. Reynolds that the great majority of cases of so-called adherent placenta were not cases in which there was any morbid attachment of the placenta to the uterine wall. Cases in which such attachment exists are rare, in comparison with the number of cases reported; but they do occur, and oftentimes are extremely difficult to manage. In cases where a patient has had, during her pregnancy, a threatening miscarriage with hemorrhage, it is very common to find the placenta morbidly adherent over the area, where, evidently, the previous placental separation had taken place. The partial separation, with its accompanying hemorrhage, seems to set up an inflammatory action sufficient to cause an adhesion. The necessity of keeping a premature child sufficiently warm is also well illustrated in the result of this case. The popular saying, that seven months' children live, while eight months' die, is, unfortunately, entitled to some weight, if we only look at statistics. The reason, however, is to be found in the neglect to properly keep up the animal heat, the loss of which is badly borne by premature children. A seven months' child is, of itself, a curiosity, and is most carefully watched, while an eight months' child so nearly resembles one at full term, that, after the first few days, the novelty is over,

<sup>2</sup> Med. Chir. Trans., Vol. xliii, p. 276.

<sup>3</sup> Boston Med. and Surg. Jour., Vol. lvi, p. 397.

and the child is very apt to die from a neglect to keep it sufficiently warm.

An eight months' child requires just a much care for four weeks, as a seven months' child does for eight. The neglect of such precaution is apt to allow of a loss of animal heat, and a convulsion not infrequently closes the scene. Since the introduction of so-called "incubators" at the Boston Lying-in Hospital, the mortality among the premature babies has very decidedly improved. The result of the operation by Dr. Porter was most successful. At the Lying-in Hospital, there have been five cases of imperforate rectum in about 3,500 births. Four of the children were males, and one was female. One of the cases was still-born, and was the result of a pregnancy complicated with hydramnios. Three of the babies were operated upon by surgeons. Two of these lived twenty-four hours, and one for three days after the operation. In one case the malformation was not operated upon, the child dying on the third day. In the three cases which were operated upon, the babies all presented symptoms of intestinal obstruction, such as vomiting, colicky pains, and evident distress, with abdominal bearing-down efforts. These symptoms were at once relieved by the operation. The case which died without any operation showed no symptoms of any intestinal obstruction.

Dr. SINCLAIR had seen several cases in which, on attempting to empty the uterus *post partum* on account of hemorrhage, the placenta was found adherent and sometimes had to be removed piecemeal. In Sir James Simpson's Edinburgh collection is a fine specimen of adherent placenta, presented to the museum by the patient's husband, as a warning against the practice of pulling on the cord by midwives. Calcareous placenta are not necessarily adherent; but the children in such cases often die in utero on account of impaired nutrition.

Dr. BLAKE said it was not uncommon to find degenerative changes and calcareous deposits in the placenta, with adhesions in some cases. In one case the connection was very intimate, of a fibroid or cord-like nature.

#### THE SURGICAL TREATMENT OF UMBILICAL HÆMORRHAGE IN THE NEW-BORN.

Dr. REYNOLDS inquired if there were any peculiarities in the technique of the surgical treatment of hemorrhage from the umbilicus in the new-born, referring to a case with hemorrhagic diathesis, which Dr. Porter had treated successfully.

Dr. PORTER replied that it was well recognized that, in cases of hæmatophilia, all cut, wounded, or abraded surfaces bleed; that, in this case, the cord was transfixed cratically at the umbilicus by two large glovers' needles, and an ordinary silk ligature tied around and behind them, the surface dusted with iodoform, a pad of borated absorbent cotton placed over them, and the whole held in place by a broad band of adhesive plaster, which nearly encircled the infant's waist. There was complete arrest of the bleeding for twenty-four hours, when the ligature commenced to cut through, and from the cut surface the blood to ooze.

The ligature was removed, the needles readjusted, and a narrow piece of ordinary cotton bandage, twisted into a cord, and tied behind the needles just sufficiently tight to control the bleeding. This cord of bandage was so soft and broad that it did not cut, and was left

in place for nearly a week, and there was no subsequent bleeding, the umbilical cicatrix forming naturally. During the local treatment by ligature, the infant was medically treated by Dr. W. L. Richardson, the attending physician, by large and frequent doses of tinct. ferri chlor. The child recovered. It seemed to the speaker that the successful issue was due to two causes: the use of a narrow, twisted cotton bandage, as the ligature under the transfixing needles, and the free exhibition of iron.

#### NORFOLK DISTRICT MEDICAL SOCIETY.

S. A. POTTER, M.D., SECRETARY.

MEETING, April 26, 1887, the President, Dr. WILLIAM P. BOLLES, in the chair.

#### THE ROSLINDALE DISASTER.

Dr. C. W. SPARHAWK spoke upon

#### THE NATURE OF THE INJURIES.

The external injuries were due chiefly to bruising and crushing. The number of such wounds upon a single body was often surprising. It was a noticeable fact that patients often failed at first to refer to injuries of very serious character which appeared later, so that a person's assertion that he was not wounded, or but slightly, was of no value whatever without a complete physical examination. External wounds have not healed as satisfactorily as is usual, and in some cases owing to the imperfect early dressings, and the depth of the crushing, wounds had to be opened and allowed to heal from the bottom. Internal injuries were very obscure. Most of the patients suffered about the ribs or spine. There were fractures of the ribs near the vertebrae, and injuries to the costal cartilages.

Brain symptoms, as vertigo, impairment of the memory, disordered mental action, occurred chiefly in the aged.

Nervous symptoms were very prominent in the majority of patients, and took the form usually of "nervousness" or emotional irritability. Those without serious injury appeared to suffer the most from this cause. The menstrual function was affected in many. As a rule the gravity of the cases was underrated.

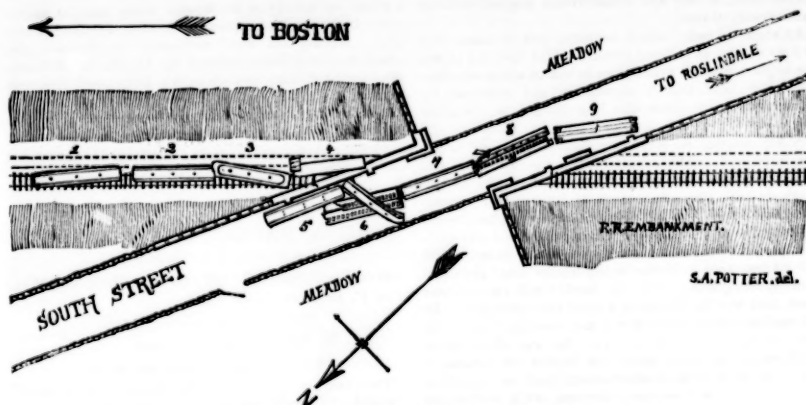

Dr. O. H. HOWE, speaking of the wounded brought to the Boston City Hospital, confirmed Dr. Sparhawk's observation in regard to the symptom "nervousness," and mentioned cases in which it had persisted for several days. Pain in the back, usually without obvious lesion, had also been complained of by most of the patients, in some instances even until they left the hospital.

Dr. J. A. TANNER, who had been in several minor accidents, had experienced the irritability to which reference had been made, and it had lasted in his case for several days. He had noticed that ladies were more strongly affected than men; also, that when an accident happened upon the water, these nervous symptoms did not appear. He explained their absence by the fact that an accident upon the water is accompanied by neither the suddenness nor shock which characterizes a railroad disaster.

Dr. E. P. GERRY read a paper upon

#### INJURIES TO THE BACK IN RAILROAD ACCIDENTS,<sup>1</sup> and also made remarks upon the influence of the dis-

<sup>1</sup> See page 468 of the Journal.

BIRD'S-EYE VIEW OF ROSLINDALE DISASTER.

## EXPLANATION.

The parallel continuous lines upon the embankment, represent the existing track; the dotted lines, a projected track. The bridge was built to accommodate two tracks, but was actually crossed by one. The train was composed of nine cars, and was moving toward Boston.

The report of the Railroad Commissioners states: "The original cause of the disaster was the breaking of the hangers at the joint-block at the north end of the Hewins truss (the western truss). The strain which broke the hangers was probably given when the engine driving-wheels passed over them, and there was a slight depression of the bridge when the engine left it. This depression had increased when the first car left the bridge, so that, as it went up off the bridge, it jumped the truck to the east; and its rear truck was torn from it. The second car dropped still farther, receiving a much more severe concussion at the end of the bridge; but the train of seven cars behind it crashed into its rear and threw it up over the edge of the

abutment, displacing both its trucks and leaving them under its rear end. When the second car struck the abutment, the third car was driven against it with such force—that car being just upon the point of leaving the solid part of the bridge at the middle of the truss—that its Miller platform was crushed on top of, and into the platform of the second car, and became inextricably entangled with it. This may have saved the third car from going into the street, as it must have formed a very strong and close connection between the two cars, and must have greatly helped to carry the front end of the third car over the chasm."

The fourth car struck the abutment, its upper part sliding forward onto the embankment, the remainder falling into the street. The top of the sixth car was separated from its sides, and thrown across them. The eighth car lay upon its side, partly telescoping the seventh. The ninth car rested upon its top. The remains of the bridge and track lay chiefly along the southern abutment.

aster upon the menstrual function. He had no doubt that such accidents profoundly affected the female. Of twelve cases, in regard to which he had made special inquiry, eleven had anticipated their period by from seven to ten days, and one, (a sister of one of the injured,) who was menstruating at the time of the accident, stopped, and began again after two or three days.

DR. T. A. DEBLOIS stated that in conversation with a Pullman car conductor, as to the wisest thing for a passenger to do in case of a railroad accident, he had been advised, if he were riding in an ordinary car, to cling to the seat, but, if in a Pullman, to catch hold of something at the top of the car. The top of an ordinary car may come off, that of a Pullman never does; in addition to which the upholstery of the seats in the Pullman not being fixed would move.

DR. E. G. MONSE had under his care a young woman of between eighteen and twenty years, who went down in the fourth car. The chief injury was to her back. There was tenderness over the spine, headache, tingling and prickling in both lower limbs. At first she would probably have fainted, had she attempted to walk. Her menstruation was unaffected, and she is now apparently recovering.

DR. J. H. MURRAY reported the case of a man who when extricated from the car was unconscious, but, soon recovering, assisted in the removal of the wounded, went to Boston the same day, and also the next. On the second day after the accident, he presented the following symptoms: dilated pupils, painful respiration, a pulse of sixty beats to the minute, irregular,

intermittent, and excited to one hundred upon the least exertion, tenderness over the dorsal, lumbar, sacral, and coccygeal regions, pain in the ankle, knee, and hip of the right leg, diminution of sensation and motion in the same limb, and an inability to bear weight upon it, restlessness, sleeplessness, and emotional irritability.

His condition remained constant for seven or eight days, and then began gradually to improve. He now shows every indication of ultimate recovery.

DR. P. C. KNAPP said that it was interesting to see how few of the cases reported injured in this accident, showed symptoms of injury to the central nervous system. In the individual, where injury has caused some gross lesion, such as laceration or fracture, it is rare to find also present, that group of obscure nervous symptoms, erroneously classed under the heading of railway spine. Perhaps it might be also true that in an accident where the results were so severe and caused so many fatal injuries, the number of cases of milder injury such as give rise to these nervous symptoms, might be small. Most cases of so-called "railway spine," however, have nothing to do with the spine, although many serious affections of the vertebrae and cord may arise from such injuries. Among these affections are true spinal concussion,—a rare and transitory disorder—fracture of the vertebrae, spinal hemorrhage, myelitis, and strain of the muscles and ligaments of the vertebral column. Beside these true spinal disorders, there is a large class of obscure chronic cases, which, following the dictum of Charcot, it has been the fashion

of late to call hysteria. Functional disorders of the nervous system are not uncommonly produced by railway injuries—neurasthenia is not infrequent, but hysteria is distinctly rare. It is generally believed now that many of these more chronic disorders are organic and are caused by a slight sclerosis of the central nervous system. Even in hysteria the prognosis is grave, and in organic disease the patient rarely recovers.

Dr. H. C. ERNST considered that we should wait from six months to a year in order to see the characteristic symptoms of "railroad spine," and recommended that the cases now under discussion be reported again at the end of a year.

Dr. KNAPP believed that a careful study of just such cases as those resulting from this accident was what was required to dispel the obscurity at present involving the whole subject of "railroad spine," and hoped that such a study would be made.

Dr. ERNST inquired if it was not as yet too early for even an expert to diagnose between a malingerer and a case of "railroad spine."

Dr. KNAPP replied that although the symptoms of the true spinal affections he had spoken of—strain, fracture, concussion, hemorrhage and myelitis—might be looked for soon after the accident, the more chronic conditions, such as hysteria, functional disease, or sclerosis were of slower development, and it was now a little too early for them to manifest themselves.

THE PRESIDENT raised the question as to whether the determination of damages in railroad accidents came properly before the physician or lawyer.

Dr. ERNST, considered that a physician when acting as such, should confine himself to medical questions entirely.

Dr. E. G. MORSE cited a case of damages recently settled by the Old Colony Railroad, in which the road chose one physician, the patient a second, and these two a third. The three physicians determined the amount of damages.

Dr. G. W. GAY said that while acting in the capacity of attending physician or surgeon, it is wiser and better to express no opinions, and to give no advice in regard to the financial part of the case. In the great majority of cases an expression of opinion on this subject will incur the displeasure of the patient, from the fact that his ideas of compensation are naturally much higher than those of an outside party. Should the physician see fit to name a sum as being, in his judgment, proper for settlement of the claim, he should not hesitate to declare it openly and freely to both parties, and, if need be, he should give his reasons for his conclusions.

Dr. GAY had been told that the superintendents of two railroads in this vicinity had expressed the opinion, that cases of personal damages are settled more reasonably and fairly by the arbitration of physicians, than in any other way.

Physicians not only have their knowledge and experience upon which to base their opinion, but, as a rule, their training prevents their judgments being very much warped by their sympathies. They, of all men, can form an intelligent idea as to the permanency of an injury, as well as to the degree of disability imposed upon the injured party. No one will deny that the physician is the proper person to decide as to the genuineness of the symptoms complained of by the

patient. This is one of the most important, as well as most difficult parts of cases involving suit at law for personal injuries. Are this man's complaints consistent with his appearance and his actions? Are similar cases met with in which there are no legal complications? As a rule, the two classes of cases present a marked contrast, and physicians are, other things being equal, the proper persons so decide these questions, and also, it would seem, to award the amount of damages.

Dr. F. W. DRAPER said that while, in a broad, legal sense, all men are equal, yet in assessing damages, as in the cases under discussion, the elements of vocation and station in life should be considered. In the matter of the relation of the physician or surgeon to his patient, he thought that the less the medical attendant meddled with his patient's legal affairs the better; but that as a duly commissioned referee, he might properly act in any case that presented, his more accurate knowledge of the claimant's condition and prospects, rendering him peculiarly competent to make a just award.

Dr. H. C. ERNST spoke upon

#### APPLIANCES USEFUL IN SUCH AN EMERGENCY.

In thinking of what appliances may be useful in case of such an accident as this, there are two considerations to be borne in mind; first, that the physician will be in a hurry, and, consequently a thing to be of use must be small in bulk and easily carried; second, that the physician must know where his apparatus is, and not be obliged to hunt for it.

In a railroad accident the injuries to be dealt with are all such as belong to acute surgery: fractures of all kinds, cuts, bruises, spinal injuries.

One of the greatest difficulties is to find splints which will answer all demands. A patient is often injured by transportation as well as by the accident. The splints which best fill the requirements of compactness and portability, are those known as Levis'. They are of copper, nickel-plated; are perforated, flexible, of all sizes, and easily applied to any limb. A set of them comes in a box of moderate size, which can be easily carried.

Next to that of splints is the question of the treatment of wounds. Believing, as I do, that suppuration is caused by the activity of bacteria alone; that bacteria always come from without, and that if they do not obtain an entrance, a wound will invariably heal by first intention, the prevention of such entrance becomes a point of cardinal importance. One of the few unquestioned facts regarding germicides is that corrosive sublimate is the most powerful. The error committed by most surgeons is that they use it in too great strength. A 1-1000 solution will destroy bacteria instantly. But such a strength is appropriate to the laboratory experiment in which a test-solution is used containing multitudes of bacteria in full vigor, rather than to a wound where there are but few bacteria. For the latter purpose, a 1-10,000 or 1-15,000 solution, repeatedly applied, is all that is necessary, and, if repeated, is, I believe, just as effective as the stronger. The stronger solution hurts the tissues and may readily produce poisoning.

Corrosive sublimate is easily carried in the form of compressed tablets, one tablet (such as those of Wyeth) to a pint of water making a 1-1000 solution.

As suppuration often starts from stitches, it is a

matter of consequence to have needles and thread aseptic. Efforts have long been tried to make them so. Many receptacles have been made, but none ever do or can prevent the exposure of the thread to the air.

A method used by the speaker in laboratory work, is to expose needles and thread in a bottle stoppered with cotton-wool, to moist heat, employing the same principle as is used in sterilizing fluids. The bottle, or test-tube, containing the needles and thread may be placed in some vessel, as a small tin-pail, containing a moderate quantity of water. Upon the vessel is to be placed a loose-fitting cover. The water is to be raised to the boiling point and a steam bath maintained for fifteen minutes. Needles and thread thus prepared can be kept indefinitely, will not occasion pus, and the needles do not rust, except after some time. But the method is extremely easy of application to hospital use. If dry heat is used, the same essential principle is carried out, and the time when the needles and thread become sterilized is marked by the cotton-wool plug turning a light brown. (But the moist sterilization is much the better.) The needles and thread must, of course, remain in the bottle or test-tube until used.

Bandages are necessary. There are the ordinary roller, of which, however, it is difficult to carry a large supply, and the Esmark triangles, the applicability of which is almost endless.

It should be said that great credit is due the people in the neighborhood of the accident for the promptness of the assistance rendered. Thirty-five minutes after the catastrophe occurred, the last wounded man was being taken from the train, and the dead, with one or two exceptions, had been already removed.

DR. B. E. COTTING, on being called upon, said that after an accident, like that under consideration, the first thing to be done was to relieve at once the injured from immediate danger and distress, and then to put them in a suitable condition for removal to places where they could be properly and thoroughly cared for, their homes, hospitals, or other permanent shelter. To this end severe hemorrhages should be checked at once, fractured limbs stayed up, wounds covered, bruises bound up—those most dangerously off first attended to so far as practicable. All this need be temporary only, to render transportation as little dangerous and painful as possible. At the place of the accident, for most temporary purposes, anything that comes to hand may be made use of, strips and fragments of cloth, towels, handkerchiefs, etc. (a young lady once tore up her petticoat for him to make a tourniquet of, for an injured friend bleeding dangerously.) Strips of bark, of boards from fences, bundles of twigs, or of straw even, will answer for temporary splints (he had used such), and hay or moss may do for padding. In short, whatever one can lay hands on; precisely as he would adjust for removal a wounded man in a street accident. Loammie Baldwin said that "to be a good engineer one should know how to bore with a jack-knife, and to whittle with a gimlet"; so should a practitioner be ready to avail himself of whatever falls in his way; and above all, keep himself calm, even at the risk of seeming indifference.

On arriving at destination the injured should be given up to their chosen attendant, who will make all required re-adjustments, and supply all previously unavoidable deficiencies.

Dr. Cotting would add that he had been surprised to hear the use of triangular bandages attributed to Esmarck. The use of handkerchiefs, triangular, square, and oblong, for all kinds of fractures, or injuries where bandages are required, was a hobby of Dr. Mayor, of Lausanne, introduced by him half a century ago.<sup>1</sup> The practice became noted everywhere in this country as well as abroad. The number of applications made by him was truly surprising, and his methods are in reality worth studying. As temporary resorts they are invaluable.

## AMERICAN SURGICAL ASSOCIATION.

ANNUAL SESSION OF 1887.

The annual meeting of the American Surgical Association was held in the reading-room of the Army Medical Museum, Washington, D. C., May 11, 12, 13, and 14, 1887.

FIRST DAY, WEDNESDAY, MAY 11.

MORNING SESSION.

The Association was called to order at 11 A. M. by the President, DR. HUNTER MCGUIRE, of Richmond, Va.

PRESIDENT'S ADDRESS.

THE NEED AND VALUE OF CO-OPERATIVE WORKS IN SURGERY.

To preside over a body of men, each one of whom is daily, almost hourly, doing something to lessen human suffering, and to add to the life and comfort of his fellow-men, is indeed a proud distinction. I shall venture to occupy your time briefly, not with a discussion of some surgical subject, for the programme shows how rich the supply of material will be in this direction, but with some remarks concerning the need and value of coöperative work in our profession, and afterwards, in suggesting some changes in the management of the meetings of this Association. Nearly every advance in whatever is accomplished by human enterprise is secured by coöperative effort. Every department of life is full of illustrations of the power of association in the accomplishment of great purposes, while the illustrations are almost as numerous of the failure of individuals to attain those ends, because they work unaided and alone. (Many illustrations of the beneficial results of coöperation in other departments of labor were cited from history.) Advance in surgery can be more surely made by associations such as ours, than by any individual efforts of man. The day has passed when the dictum of one man, no matter how exalted he may be, is received without question. The difficulties which beset us are numerous. Disease presents problems difficult of solution. We cannot apply to the human machine the fixed rules by which inanimate bodies are governed. The result of the work of the surgeon in private houses and in public hospitals must be different. Besides this, it is necessary to get rid of the rubbish with which we are too often flooded by ignorant, but ambitious, contributors. This is an easy task; but it is more difficult to know when to reject the material presented by skilful, but unscrupulous workers, who, to gratify their own personal vanity, make false returns of their labors.

I have mentioned only a few of the difficulties by

<sup>1</sup> Nouveau Système de Ligature Chirurgicale, Paris, 1838.

which we are surrounded. Their influence over the true man, the true surgeon, should be to make him more patient, inspire him with more zeal, and teach him more plainly the value of coöperative industry. For the developments yet awaiting us, we must be indebted to the contributions which every patient and conscientious laborer may bring to the common stock of ascertained knowledge, and we shall accomplish this best by the cultivation of a broad and generous appreciation of each other's work, from which every particle of envy at the success of others has been eliminated, by the hearty commendation which we give to all who have enlarged the boundaries of surgical science, or who have improved its art.

In concluding his address, the President made the following suggestions:

(1) The formation of a business committee, to prepare the work of the Association. The committee should select two general subjects in surgery, to be discussed at the morning sessions of the first and second days.

(2) The address of the President should be limited to half-an-hour, readers of papers to the same time, and those who take part in the discussions to fifteen minutes.

(3) I venture to suggest the abrogation of Article 9 of the Constitution. This will allow us to admit to Fellowship some men in this country who are really needed in the Association. While I believe in the rigid observance of the code of ethics of the American Medical Association, and the absolute necessity of its enforcement in that body, there is no need for it in our Association. The only code that we should have is scientific work.

(4) That the report of the Committee with reference to the American Congress of Physicians and Surgeons be adopted.

(5) That the Constitution be so amended that propositions for membership shall lie over for one year. The qualifications for Fellowship should be age, experience in surgical work, scientific attainments, with general culture.

A committee of five was appointed to take into consideration the suggestions offered by the President. The Committee consists of Drs. S. A. Gross, C. H. Mastin, D. W. Yandell, Moses Gunn, and C. Johnston.

The Association then went into executive session.

#### AFTERNOON SESSION.

#### THE EXPLORATION OF THE BLADDER BY THE SUPRA-PUBLIC METHOD,

by F. S. DENNIS, M.D., New York.

The supra-pubic operation of to-day is practically the same as the old operation; the only improvement has been improvement in technique. A brief historical account of the operation was given. The first reported operation was that of Franco in 1851. From that period to 1879 the operations were not numerous, but from 1879 to the present time the operation has been done with such success as to attract attention throughout the world. The time is not far distant when practically the only two operations will be supra-pubic lithotomy and litholapaxy. Supra-pubic lithotomy is simple in technique, safe in execution, free from injury to the reproductive organs, radical in results, curative in application and brilliant in statistics. The many serious accidents attending the lateral operation are avoided.

*Technique of operation.* For a few days before opera-

tion a milk diet should be employed. The day previous to operation the bowels should be moved with castor oil. The morning of the operation an enema should be used so as to empty the rectum for the introduction of the rubber bag. The parts should be washed with anti-septic solution. After the patient has been etherized, the surgeon should introduce a rubber bag into the rectum so as to be above the internal sphincter. Into this twelve ounces of warm water is to be introduced. This quantity will have to be increased or diminished according to circumstances. The danger of rupture of the rectum in elderly people and young boys, should be borne in mind. The urine should be withdrawn and six ounces, more or less, of an antiseptic solution introduced into the bladder. The catheter may be left in the bladder and stopped with cork, and this will serve as a guide to cut upon. The distention of the rectum and bladder increases the distance from the pubes to the anterior cul-de-sac of the peritoneum to three inches. The incision should be made in the median line and should extend for three or four inches above the pubes; when the transversalis fascia is reached the use of retractors on the principle of the eye-speculum facilitates the operation. Having divided the fascia the end of the catheter can be felt and cut upon as a guide. The bladder may then be seized with two tenacula and opened. Where free exploration is desired, sutures are introduced on each side of the incision. The stone is removed either with the fingers or forceps. The bladder may then be washed out. A catheter should be introduced through the urethra, but not left longer than twenty-four hours, on account of the danger of exciting traumatic urethritis. In the majority of cases the wound of the bladder should be left open. In cases of calculi, the condition of the tissues is such that primary union is unlikely. In certain other conditions such as rupture, the wound may be closed, for here the condition of tissues is different. The abdominal opening is to be closed and a tube introduced.

This operation is indicated (1) for hard, large calculi, and in persons suffering with paraplegia and deformities rendering lateral lithotomy difficult. (2) For removal of certain foreign bodies such as hairpins, etc., and for the treatment of chronic cystitis. (3) In cases of tight stricture, fibroma of prostate, tumors of the bladder, and for rupture. In its extraordinary simplicity, its reduced mortality, its freedom from danger and safety for the general practitioner, it compares well with litholapaxy.

The speaker had collected one hundred and twenty-four cases of supra-pubic operation for stone, done since 1879. Previous to this date, the rate of mortality was thirty per cent. Since then the mortality has been reduced, there being eighteen deaths, a mortality of fourteen per cent. Seven of these deaths may be justly excluded, giving a mortality of nine per cent. According to Sir Henry Thompson's statistics, the death-rate from the lateral operation is twelve per cent. According to the same authority the mortality of lithotripsy is six per cent. In considering the mortality of this operation, two facts are to be considered. The mortality may be improved by more rigid antiseptic precautions. The second fact is that the operation has been limited to the largest stones. When the smaller stones are included, the death-rate will be reduced. Specimens showing the position of the bladder under various conditions were then shown.

**SUPRA-PUBIC CYSTOTOMY FOR OTHER PURPOSES  
THAN THE REMOVAL OF CALCULI,**

by JOHN H. PACKARD, M.D., of Philadelphia.

He referred at length to the history of the operation as it appears in cases recorded from 1750 to 1886. The opinions of authors in regard to the hypogastric operation in general, and especially with reference to the evacuation of urine, was next given. In regard to the anatomical relations of the peritoneum to the bladder and abdominal walls, much diversity of opinion was found to exist.

In 1883, the speaker removed by supra-pubic cystotomy, a piece of shawl-pin, five inches in length, which had been passed through the urethra. Since then he has done this operation a number of times. In cases of retention of urine from stricture, where a fair attempt to pass an instrument fails, he draws the urine by aspiration. In a short time an instrument can usually be passed. He did not recall a case in which it was necessary to repeat aspiration. The following cases were cited:

July 7, 1865. Mr. G., eighty-five years old, had retention due to large prostate. The bladder was greatly distended. The urine was drawn off with a long catheter, but he desired more permanent relief, supra-pubic cystotomy was performed, and a glass ovariotomy tube, bent like a tracheotomy tube was introduced. The patient improved decidedly, but suddenly died July 9th, from heart failure, the result of sudden exertion.

J. C., aged forty-three, came under observation January 21, 1885, at Penna. Hospital, with a history of retention, the result of old stricture. The bladder was greatly distended and no instrument could be passed. There were frequent chills and profuse sweats. The next day Dr. Thomas G. Morton made a perineal incision, opening an abscess, the catheter then passed into the bladder. The following day the bladder was again distended; supra-pubic incision was then done. A catheter passed through the abdominal opening and the neck of the bladder escaped through the perineal wound. On February 7th, a large mass of slough came from the abdominal wound. The patient then rapidly improved and was discharged cured, April 21st.

H. F., forty-three years old, had retention for four days. The penis, scrotum, and skin of abdomen were swollen, tense and rigid. Free incisions were made. The bladder was opened and a tube introduced. On June 4th, an instrument was passed by urethra. On July 13th the patient was discharged and has continued well.

Mr. S., age sixty-three, admitted with enlarged prostate and frequent attacks of retention. August 13, 1886, supra-pubic incision was performed and the bladder opened. Although the condition was improved the patient died of exhaustion August 29th.

The next two cases occurred at Penna. Hospital, within past few weeks. W. E., age seventy, was admitted April 24, 1887, with retention due to enlarged prostate, supra-pubic cystotomy was performed and a large quantity of putrescent urine removed. A rubber tube was passed into the bladder. The urine contained albumen to the amount of one-half its bulk. Granular casts were also found. A typhoid condition developed and the patient died on the fourteenth day after admission.

R. W., age forty, was admitted the same day. He

had double inguinal hernia and double hydrocele. He had passed no urine for fourteen hours. Catheterization was attempted without success. Supra-pubic incision was then performed and a rubber-tube introduced. He has done well since then, and is beginning to pass some water by the urethra.

**Method of Procedure.** The fullest antiseptic precautions should be observed in these cases. In most of the cases on which the author had operated the question whether or not the bladder should be distended had not presented itself, as the bladder was already over-distended. The bladder should never be more than moderately distended, not more than six or eight ounces of a boric acid solution being employed. To retain the water in the bladder a convenient method is to bend the urethra on itself and hold it in this position. There seems to be more advantage and less risk from distension of the rectum. Many writers recommend that the bladder be steadied by an assistant, but this was regarded as needless and objectionable.

The incision through the skin should be free enough to give ready access to the deeper parts. When the bladder is reached it is desirable to secure it in some manner before puncturing. For this purpose a small double hook may be used. A small tenaculum may answer. When a large opening is to be made a double ligature is perhaps the best device. In cases of retention the curved trocar and cannula may now be at once used. The cannula should afterwards be substituted by the tube. The speaker's custom is to make the opening in the bladder just large enough for the tube. The proper point for making the opening seems to be about at the middle of the exposed portion of the wall of the bladder, which would be about one inch or one-and-one-half inches above the pubes.

The drainage-tube should go well into the bladder, and have lateral openings only near its extremity. The external end may be closed with a cork or clip or by bending it. In old men with atonied bladders he had sometimes used glass tubes. If a large opening has been made in the bladder it may be closed around the tube with a few cat-gut sutures. The tendency of the wound is to close quickly except where the tissues as well as the general system are in bad condition. The edges of the wound in the skin can be apposed with sutures of cat-gut or silk-worm gut.

In concluding, the speaker asked, "If the supra-pubic section had been first tried, and generally adopted, is it likely that the perineal operation would have been afterwards performed on account of its greater ease, simplicity, and efficiency?"

**TO WHAT EXTENT CAN WE CLASSIFY VESICAL CALCULI FOR OPERATION? WITH A REPORT OF CASES AND REMARKS ON THE DIFFERENT METHODS EMPLOYED,**

by A. VANDER VEER, M.D., of Albany, N. Y.

After a few preliminary remarks, the speaker gave detailed histories of forty-one cases which he had operated on. The various methods employed were lithotomy, rapid dilatation of the urethra, and Bigelow's operation (litholapaxy).

There were seven cases of perineal lithotomies, with two deaths and five recoveries, the former being very old men, with large stones. Of attempted litholapaxies and an immediate perineal lithotomy, there were two cases, both resulting in death, one occurring in the speaker's practice, the other in the practice of a friend.

Both were severe cases of large stone, the patients presenting a history of much suffering through many years. Of dilatation of the urethra in the female, and washing out of fragments or removal of stone entire, there were six cases, all recovering with no complication whatever. Of urethra-calculi in the male, there were four cases, all recovering. Of simply lithotripsy in the male there was one case, followed by recovery.

Of attempted litholapaxies, but which were not completed, there were four cases, three ending in death, and one, the stone hiding in a sac, later underwent perineal lithotomy and recovered. One was probably complicated with some form of tumor of the bladder, and a history of chronic disease of the kidneys. One was a case of chronic alcoholism, one was complicated with sacculated bladder, and the last two were cases of surgical kidney of the very gravest kind.

Of the litholapaxies in the male, there were eighteen patients having twenty-two operations, four requiring a second operation. Of the number, sixteen recovered and two died. Of the latter, one after the first and one after the second operation.

With reference to supra-pubic lithotomy, the author said that, with the excellent results we are ever likely to obtain from rapid lithotripsy, the operation must necessarily deal with severe cases of large, and, in some instances, sacculated stone. He did not believe that we should ever expect from it as great a per cent. of recoveries—it is hardly possible. A table of reported cases of supra-pubic operations was given, showing in 142 adult cases a mortality of 22 per cent.; in children under fifteen years of age 113 cases gave a mortality of 10.5 per cent.

• The operation of litholapaxy is certainly indicated where the stone is small or of moderate size, and, contrary to the teachings of a few years since, can be done in very young male children, with proper instruments. In male adults, if there is severe chronic cystitis, no matter what is the size of the stone, the supra-pubic or some form of perineal lithotomy seems best. The cystitis can then be successfully treated, and there is less danger of a reformation. The speaker thought that it would be found by future statistics that cystitis has much to do with the necessity for a second or third operation. He thought that contracted bladder in the male, with adhesions, had not received the attention which it demanded. This must, in some instances, embarrass supra-pubic lithotomy. On anatomical grounds, the supra-pubic operation will be much simpler in the youth, as the bladder is much higher in the pelvis at this time of life. In girls, rapid dilatation or supra-pubic lithotomy will undoubtedly reach all cases. In adult women, vaginal lithotomy may be added.

The discussion of these papers was postponed until Thursday morning. Adjourned.

(To be continued.)

#### NEW YORK COUNTY MEDICAL ASSOCIATION.

STATED meeting April 18, 1887.

DR. WM. T. LUSK reported a

##### SUCCESSFUL CASE OF CÆSAREAN SECTION.

The patient was twenty-four years of age, and a native of Ireland. On March 21, 1887, she was sent from the Mothers' Home, on Staten Island, to his ser-

vice at Bellevue Hospital, on account of deformity of the pelvis resulting from hip-disease. The latter dated from the age of eleven, and on account of it she had at this time been sent to a Dublin Hospital for treatment. She was discharged cured; but during her pregnancy she noticed some suppurative discharge from the old sinuses which had formed at this period.

On March 22d, Dr. Lusk visited the hospital and made an examination of the patient, when much to his surprise he found that she was already in the early stage of labor. The pelvis was ascertained to be of the type known as the Nægele oblique, and having given its diameters, which showed very marked contraction, he said that with the sanction of Drs. Isaac E. Taylor and H. J. Garrigues, who saw the case in consultation, he determined to perform Sænger's operation. Craniotomy, he went on to say, was generally considered comparatively simple; but, with the pelvic dimensions that were present in this case, he had no doubt that the danger from it would be greater than that from Cæsarean section, provided the latter were performed sufficiently early. Dr. Taylor was of the opinion that the case was nearly identical with one in which Dr. Lee performed craniotomy, and where the patient died. Dr. Lusk also referred to a similar case in the practice of Dr. Studley, where the pelvis was fractured in the effort to deliver the child.

As the patient was already in labor, no time was to be lost, and he determined to operate at once. Both the private pavilions of the hospital being occupied, he was obliged to perform the operation in one of the wards. It was commenced at 3.30 p.m. The abdominal incision was made through the linea alba, and extended from just below the umbilicus to a point two or three finger's breadth above the symphysis pubis. The peritoneum having been slit up, the uterus was everted by the hands over the abdomen. When the organ had been thus turned out, the intestines were placed behind it, and both the intestines and uterus wrapped in warm towels; a solution of bichloride of mercury, 1 to 10,000, being used. A rubber-tube was then placed around the uterus, in order to prevent hemorrhage. In opening the uterus an incision two inches long was made near the lower segments, and with the scissors afterwards increased to five inches. Owing to the pressure upon the vessels secured by the elastic ligature, the incision was nearly bloodless.

The child was found with the head presenting in the left occipito-anterior position, and on being extracted, was in a cyanotic condition, from the pressure caused by the rubber; but through the efforts of Dr. A. B. Ball it was successfully resuscitated. With the finger the membranes and placenta were readily detached from the uterine walls, and the delicate structures described by Leopold was at this time beautifully exhibited. All through the operation the intestines were held back by warm towels. The uterus remained of a pale waxy color, on account of the elastic ligature.

In closing the uterine wound, thirty-four carbolized silk sutures were employed, of which sixteen were deep, and the rest superficial. In the deep sutures, he said, special pains should always be taken to avoid the mucous membrane of the cavity. The Lembert suture was used in making the superficial sutures. When the rubber-band was removed from the uterus the blood slowly returned to the pallid organ. At first it assumed a delicate rosy hue, finally a deep purple. A

slight oozing was then observed at one point. The uterus was then returned to the abdominal cavity, and a drainage-tube inserted behind the organ. Silver-wire sutures were employed to close the abdominal wound. At the end of the operation, which lasted one hour and fifteen minutes (twenty minutes of this time being taken up in endeavoring to stop the oozing referred to), the patient was in excellent condition.

For three days after the operation the temperature did not go as high as 100°. Then there was a little tympanites, and it went up above 101°; but a Scidlitz powder had the effect of promptly reducing it again. On the fifth day the drainage-tube was removed. Immediately after the operation the discharge from it was stained with blood, but it soon became colorless. Dr. Lusk said that the tube was not, in fact, needed in this case; but at the same time there was a certain feeling of security in knowing that it was in position. On the day following the removal of the drainage-tube there was some oozing from the opening left by it. At the end of a week the abdominal sutures were removed. At this time the temperature would usually go up to about 100.5° in the evening, and then fall again by morning.

On the ninth day some fluctuation was detected in the time of the abdominal wound, and a little pus was evacuated; after which the temperature became nearly normal. At the end of two weeks, however, the temperature went up suddenly to nearly 103°. Still, no trouble whatever could be discovered about the abdomen, and as the patient complained of pain in the right hip, an examination was made which revealed an accumulation of pus in the site of the old sinuses which had given trouble during pregnancy. Since that time the patient had continued in most excellent condition. Ever since the second day, by which time she had recovered from the effects of the ether used for the operation, she had been able to take abundant nourishment. She passed her water freely, was comfortable in every way, and on the whole seemed to think it was quite an easy way of having a baby. There had, indeed, been no question of her recovery at any time. The infant now weighed ten pounds, and was also doing perfectly well.

DR. SILVA, lately house-surgeon in Bellevue Hospital, who had had charge of the case, stated that the patient did better altogether, than any other case of laparotomy that he had the opportunity of observing during his service at the hospital.

DR. T. J. KEARNEY inquired whether it would not have been better in such a case as this to perform Porro's or Tait's operation, in order to prevent the woman's becoming pregnant again.

DR. LUSK replied that statistics showed that with the Sanger operation (more or less modified from the procedure as originally proposed), there were over seventy per cent. of recoveries, while in Porro's operation there were only forty per cent. of recoveries. It was, therefore, unquestionably a more dangerous operation. In regard to Tait's, it seemed to him that the additional risk to which it subjected the patient was by no means advisable; the extremely vascular condition of the parts constituting a serious objection.

At all events, he should not like to attempt this, in addition to Cesarean section, unless he had time to consider the matter very fully beforehand, and in the present instance the operation was undertaken in very sudden manner, as he had no idea that he would find

labor actually commencing when he made his first examination of the patient.

DR. J. R. MACGREGOR said that he had been with Dr. Studley at the time the fracture of the pelvis referred to by Dr. Lusk occurred. The patient had ankylosis of the right hip, with a projection inwards of the ramus of the pubes on that side; but it was thought that she could be delivered *per vias naturales*, with the aid of artificial assistance, until the accident occurred. The patient died, though not immediately.

DR. SILVA said that in the *American Journal of the Medical Sciences* for 1878, Vol. II, Dr. Robert Harris, of Philadelphia, had published statistics of one hundred cases of Cesarean section, and out of nineteen of the cases, all of which occurred in dwarfs, only one mother and five children were saved. In all these cases the operation was only undertaken as a last resort, when the patient was utterly exhausted; and the results certainly afforded ample proof of the importance and desirability of early surgical interference.

DR. C. S. WOOD said that in the course of his experience he had had to perform craniotomy three times, and he thought that this class of cases was without doubt as disagreeable and repulsive as one could possibly meet with. If, therefore, by this operation it was possible to save more mothers than by craniotomy, it would be a great boon. Thus far, however, statistics unfortunately showed that it saved a far smaller proportion of mothers. In two of the cases of craniotomy that he had met with, the mothers recovered, while in the third the mother was lost. Yet in one of the successful cases he labored under great disadvantages, as, not expecting to be called on to perform craniotomy, he had no instruments for the operation, and was so situated that none could be obtained on short notice. Under these circumstances he resorted to the device of manufacturing such rough instruments as he could from some shoemaker's tools; and he thought the case was of interest as showing what might be accomplished by very simple means sometimes, in an emergency.

There seemed at present to be gaining ground a sentimental notion that it was of the greatest importance to save the child; but he was one of those who believed that the mother should be saved at all hazards, whether the child was sacrificed or not; and as long as it could be shown that more mother's lives were lost by the Cesarean section than by craniotomy, he thought the latter should be given the preference.

DR. KEARNEY said that he could not agree with the views expressed by the last speaker. Dr. Bedford, he thought, had given the most rational statistics, and if, as was undoubtedly the case, it could be shown that in the aggregate more lives (of mothers and children taken together), could be saved by Cesarean section, it should without doubt be preferred to craniotomy. The matter was not merely one of sentiment; it was more than that, and involved a question of deep ethics. By simple logic alone, the justice of the Cesarean operation could be established, and he had never yet seen the objections against craniotomy adequately answered by any author with which he was conversant.

DR. LUSK said that if, in speaking of Cesarean section, was meant the old operation, as it had usually been performed, unskillfully or carelessly, and when the patient was already practically moribund, the mortality was undoubtedly very heavy. It was a fact that in most of the cases it was resorted to only when

the woman was in a dying condition, and after all other methods of delivery, craniotomy included, had been tried in vain. When it was remembered, too, that a rough and careless way of operating had also been the rule, it was no wonder that the patient died, and that such cases bore heavily against the value of the procedure. But, even under all these disadvantageous circumstances, a few cases had recovered.

At the present time it was getting to be understood that the operation should be performed, whenever this was possible, under more favorable conditions and in the same careful way as any other surgical procedure involving the abdominal cavity. The operator should take sufficient time to make out the pelvic diameters and consider fully the risks that would be encountered in performing craniotomy. If, having done this, he decided that the Cesarean section offered the best chance of success, he should make his preparations as deliberately as the circumstances of the case would admit of, and perform the operation by methods in accordance in every particular with the precepts of modern antiseptic surgery. When this course was pursued, the results were infinitely more satisfactory than those met with in the old operation, as was shown very clearly by the cases of Leopold, for instance, who had operated ten times, with only one death. In the light of his later experience, Leopold thought that he would now have been able to save even the one that proved fatal. Very few obstetric surgeons, Dr. Lusk remarked, could show a result of ninety per cent. of recoveries in their cases of craniotomy. Within the last eighteen months Harris had collected forty cases of Cesarean section, with seventy-three per cent. of recoveries; while the best results of craniotomy in these difficult cases showed only sixty per cent. of recoveries.

While he was quite aware that too implicit reliance should not be placed on statistics, other operators besides Leopold had reported four, five, or six consecutive cases, without a death. One great reason for the gratifying success of the modern operation was, he believed, to be found in the use of the rubber ligature, which so effectually prevented hemorrhage from the severed uterine structures. When this was employed, the surgeon could go to work very deliberately, and bring the edges of the wound together with the greatest accuracy. In his own case, there was absolutely no symptom during the lying-in period which was referable to the uterine wound. In conclusion, he would only say that if we were to wait until the woman was dying, instead of interfering early, as in this instance, we should only have the old statistics repeated.

Dr. W. S. GOULEY inquired what Dr. Lusk thought of the operation of laparo-elytrotyomy in these cases.

Dr. Lusk replied that this procedure was particularly adapted to a special class of cases, namely, when the head was arrested at the brim of the pelvis, and the cervix was already dilated, or in a dilatate condition. If, however, we were obliged to pass the forceps through an undilated cervix, it was a very serious operation. In case, therefore, we desired to operate early, we had to do it at a time when the conditions favorable to laparo-elytrotyomy did not exist. Of the twelve cases of this operation which had been reported, six had resulted in recovery, and six had proved fatal, the latter being cases in which success was impossible, from the conditions existing at the time.

(To be continued.)

### PHAGOCYTES AND BACTERIAL INVASION.

LATELY, attention has been directed to the part played by certain cells, chiefly derived from the white blood-corpuscles, in the removal of dead tissue and foreign substances from the animal economy by process of intra-cellular digestion. Prominence was first given to this by Metschnikoff, a Russian investigator, from the direct observation of the lining of the digestive track of certain of the lower, transparent, aquatic forms of animal life. Later, cells having a similar function were found at the place of separation of the tadpole's tail. For all these, he proposed the name of phagocytes. Subsequently, their sphere of action has been extended in a recent article from his pen, on "The Fight between Cells and the Micrococci of Erysipelas."<sup>1</sup>

From the very first, the presence of bacteria in leucocytes had been noted, but they were regarded as holding the same relation as any other fine molecules which might happen to be present in the circulation. Koch thought the cells served simply as a good nutritive soil, laying special stress on the presence of anthrax bacilli in the cells of frog's blood, although the animal itself was exempt from the disease, while in the death of the tubercle bacillus in the giant cell was seen simply an expression of its naturally short life. For him the excretory organs, above all the kidneys, were the active agents in removing the parasites from the organism. Then, too, the inflammatory reaction exercised a healing influence, although his conception of the exact manner is a little vague.

Our writer has chosen erysipelas in which to study the subject in the higher animals, since it is a disease produced by a well-characterized micrococcus, and usually ending in recovery. The action of the cells cannot be seen here in situ, as in the transparent animals; but still, if they are active therapeutic agents, changes indicative of this should be found in them and their relations after removal from the body and proper preparation.

<sup>1</sup> Vireh. Archiv., Bd. 117, s. 200.

The description of Fehleisen, who first demonstrated the bacterial origin of the disease, seems to substantiate this. Three zones are distinguished by him: The outer shows nothing to the unaided eye, but, microscopically, the lymph spaces are found to be filled with micrococci in active multiplication. Into this runs the second zone of reddening, where the inflammatory reaction is manifested by the presence of numerous wandering cells, which have taken up the micrococci and replaced them more and more. In the third zone the bacteria have entirely disappeared, the small cell infiltration is extreme, and the reaction may be said to have reached its highest point. In the paler parts of the skin, the return to normal has already begun by the re-absorption of the inflammatory products, and is accomplished with great quickness.

In further support of the theory, Metschnikoff himself examined preparations from fatal cases and from those which recovered. In the former, he found a marked accumulation of the erysipelas cocci in the cutis and subcutaneous tissue, always lying free in the lymph spaces and never in the interior of the cells. In the latter cases there was a very different picture. Here the inflammatory infiltration was much more marked, and many of the leucocytes contained bacteria. These lay included in the protoplasm of the cell, partly as streptococci, and partly as isolated round cocci. Occasionally they were surrounded by a clear vacuole, suggestive of the digestive process seen in the cells of the protozoa. All of these phagocytes did not seem to possess an equal power to take up bacteria, since, of contiguous cells, some were loaded and others entirely free. Closer examination revealed, in the former, the presence of granules of varying size and irregular outline, but deeply stained. Between these and the cocci all possible gradations were to be seen, and the conclusion was justified that these finest granules were fragments of the ingested bacteria. In gangrenous parts of the skin, on the other hand, the bacteria were found in abundance between the cells, while the leucocytes were seen to be destroyed, their nuclei transformed into small, irregular granules, not staining, and the cell-bodies into homogeneous, scale-like masses. Thus it appears that between the micrococcus of erysipelas and the leucocytes there is carried on a bitter struggle, which ends in the victory of one or the other.

These, however, are not the only actors in the scene, for the fixed connective-tissue cells also have a rôle. These are distinguished as somewhat spindle-shaped, epithelioid-looking elements, larger than the leucocytes, provided with protoplasmic projections, and having a simple round or oval nucleus, with evident nucleolus, staining but slightly in methylene blue. For these, the name of makrophyte is proposed, while that of microphyte is used to designate the small amoeboid cells with deeply-stained, lobulated, or fragmentary nucleus, and pale protoplasm.

These two kinds of cells have an entirely different function. The makrophytes do not possess the power

to eat up a single bacteria; that is the exclusive privilege of the microphytes. Their function is to take up the weakened or dead elements, and to dispose of them. Often they are so filled with these small cells and fragments, that they look like round or oval conglomerates, in the midst of which the pale nucleus is only to be found on diligent search.

Naturally, these observations must be substantiated by others. But they point in the direction towards which modern thought tends, and give food for reflection as to the possibility of translating into known terms the expression of cellular activity.

#### SUPRA-PUBIC CYSTOTOMY AND OTHER OPERATIONS FOR THE REMOVAL OF VESICAL CALCULI.

AMONG other interesting communications presented to the American Surgical Association at its late meeting in Washington,<sup>1</sup> are three papers upon genito-urinary subjects, which we take pleasure in referring to as excellent contributions on matters which have occupied much attention recently in this department of surgery. The first two, by Drs. Dennis<sup>2</sup> and Packard,<sup>3</sup> deal with the operation of supra-pubic cystotomy, the former treating especially the technique of, and indications for, the operation, the latter detailing some of its uses for purposes other than the removal of stone, and containing, also, the account of several cases.

The account of the improved modern technique is in the main good, and it only occurs to us to offer a few criticisms and additions to it. We cannot agree with the unmodified statement of Dr. Dennis, as reported, that by the distension of the rectum by the rubber bag, and of the bladder by an antiseptic solution, the peritoneum is raised three inches above the symphysis, the fact being that the elevation varies considerably in different cases, sometimes attaining a greater distance, and sometimes being so little removed that it has been wounded by the incision into the bladder. There is but little reported mention in either communication of the attempts with, and successes of, the bladder suture after supra-pubic cystotomy. Dr. Dennis thinks that the wound should be left open in the majority of cases, while Dr. Packard speaks of the use of a single drainage-tube.

In an editorial article appearing in our issue of July 16, 1885, we said, in reference to this subject, at a time when bladder suture had been less perfected, and less often successfully applied than now: "Of vesical suture, then, it may be said that, although it has not yet attained perfection, it is the thing to be sought. Its employment after the extraction of stone or the removal of new growths is still *sub judice*, however, bladder drainage being on trial in competition with it." Since then, the cases followed by immediate

<sup>1</sup> See page 480 of the Journal.

<sup>2</sup> The Exploration of the Bladder by the Supra-pubic Method.

<sup>3</sup> Supra-pubic Cystotomy for Other Purposes than the Removal of Calculi.

union of the bladder wound after application of the suture have multiplied, and the procedure has a strong band of advocates, among whom may be mentioned Ultzmann, Zesas, Von Bergmann, Czerny, Zancarol, Sklifossowski, Rauh, Miculicz, Van Antal, and others; while in this country, Keyes, Stein, Lange, have had successful cases.

It is only fair to say, however, that there are many who think, with Dr. Dennis, that the open treatment is the better method. Trendelenberg is the most extreme advocate of this view, which also numbers among its adherents most of the French surgeons, and Sir Henry Thompson. The value of any form of drainage-tubes, however modified, is beginning to be more and more doubted, and it has been recently shown, in an interesting article by Marc Sée,<sup>4</sup> that they, for the most part, totally fail to prevent the contact of the urine with the wound and surrounding tissues, and are, consequently, better omitted.

In regard to the success of bladder-suture, Schmitz's and Meyer's statistics give its numerical standing. The former's cases include all those published up to 1886, in which the bladder-suture had been applied, fifty-five in number, primary union occurring in seventeen, or thirty-one per cent., of these. The latter shows forty-one cases, with sixteen first intentions, or thirty-nine per cent., of successes, and the number has been largely added to since then. The success of the suture is by no means destroyed by pre-existing cystitis, although its chances may be said to be less good under this condition.

We find no mention in the abstract before us of a step in the technique which is, perhaps, as important as any in averting one of the disasters of the operation, namely, the necessity for leaving undisturbed so far as possible the relations of the tissues about the neck of the bladder. Great care should be taken *not* to try to pull the prevesical fat away from its position, or to bore down beneath the symphysis with the finger or with instruments. The prevesical fat should be divided *in situ*. The neglect of these precautions gives rise to opportunities for the formation of pools of stagnant urine in the pockets so formed, and these are the origin of septic phlegmon, which has always constituted one of the gravest dangers of the operation. We do not think too much stress can be laid upon this point.

The remark made by Dr. Dennis, "That the operation is indicated in cases of tight stricture," seems to us somewhat too liberal, without further modification. There are no doubt cases of stricture in which this procedure will be useful as an ultimate resort. Certainly, however, the attempt might be made of attacking the stricture *in situ* by perineal section, even without a guide, before resorting to the supra-pubic incision. It is not very often that one is obliged to desert the perineal route into the bladder through the stricture on account of insuperable difficulties. Valuable time may be gained also by the well-recognized practice of

aspiration of the bladder in cases of critical retention, as Dr. Packard points out.

It may be worth while also to call attention to one accident that *has* happened and which may be avoided by emptying the rectal balloon previous to incising the bladder, after it has been fixed by tenacula or by a stitch. In the case we have in mind the bladder was pushed to one side by the rectal bag, the rectum presented in the wound, and was incised by the operator, under the impression that it was the bladder.

We are glad that Dr. Packard has brought into prominence the uses of supra-pubic incision for purposes other than the removal of stone. In this aspect the operation has the additional interest of novelty and of a wider field of usefulness, and will tend to make more firm the belief that the operation after the many vicissitudes which it has undergone in the last hundred years has come this time to stay.

The third paper, by Dr. Vander Veer,<sup>5</sup> deals with the classification of calculi with reference to choice of operation. The conclusions reached are, that litholapaxy should be applied to stones of moderate size, but discarded in favor of lithotomy where severe chronic cystitis coexists, no matter what the size of the stone. The author does not think that supra-pubic cystotomy will ever compete favorably with lithotomy, on account of its greater mortality, but acknowledges that it is the best method with which to deal with very large calculi and with some cases of sacculated stone.

The tendency to welcome with injudicious enthusiasm the resurrection of supra-pubic cystotomy, to make its application all but universal, to the detriment of litholapaxy, and we believe also to that of many patients, was becoming so marked in some quarters—especially in Germany, where at Magdeburg, Volkmann said that litholapaxy henceforth would only possess an historic interest, and Koenig and Kramer, at Berlin, though less sweeping in their judgment, seemed to share the same opinion—that we have been glad to notice what seem to us the more just views which have been presented from time to time since these declarations. Gayon has undertaken the defence of lithotomy,<sup>6</sup> in an article, in which after an exhaustive review of the supra-pubic operation, with its modern improvements, and of litholapaxy, his concluding sentence is this: "I shall have attained my end, if I have contributed in common with others, in showing that rapid lithotomy deserves to retain the first place in the treatment of stone in the bladder, and that all surgeons should assist in maintaining it there."

Dr. Vander Veer has brought out the fact again, that with the best showing the mortality statistics of supra-pubic lithotomy cannot be reduced to much below fifteen per cent., while those of litholapaxy vary from two per cent. to six per cent. Until this difference, therefore, is more equalized than at present, the burden of proof will continue to remain with the advocates

<sup>4</sup> *Revue de Chirurgie*, No. 1, January 10, 1887.

<sup>5</sup> To what extent can we classify Vesical Calculi for Operation, with a Report of Cases and Remarks on the Different Methods employed.

<sup>6</sup> *Annales des Maladies des organes Génito-Urinaires*, December, 1886. (Des indications et contre indications de la lithotritie rapide.)

of the supra-pubic operation, certainly so far as anything like a universal application of it is concerned.

With the main conclusions of Dr. Vander Veer's paper we are therefore quite in accord, and his statements seem well and carefully considered.

#### CUTANEOUS ERUPTIONS PRODUCED BY BROMIDE OF POTASSIUM.

GRELLETY has recently read a paper before the Société de Thérapeutique, in which he calls attention to the cutaneous affections which he has often witnessed as a sequel to the administration of bromide of potassium. These are acne, impetigo, eczema, furuncles, ulcerations, etc., often of a severe and obstinate nature; the cutaneous lesion is often accompanied by gastric disorders and great nervous depression, especially in dyspeptics or diabetics, where the kidneys perform their function badly. In cases where the medicine is imperfectly eliminated by the kidneys, it accumulates in the sudoriparous glands and provokes tegumentary lesions; where there is irritation of the mucous membrane (as in bronchitis), the irritation is sure to augment under the use of the bromide, while any existing dyspeptic troubles are sure to be aggravated, especially when the preparation is taken on an empty stomach, or insufficiently diluted. Arsenic is considered the best antidote of bromide, and Besnier is accustomed in his practice to give the two medicines together, that is, three, four or five drops of Fowler's solution with every three, four or five grammes of bromide.

Among the various eruptions produced by prolonged use of bromide of potassium, one of the most annoying is the furuncular, which is especially prone to follow the administration of large doses of bromide in diabetes. In diabetes the secretory function of the kidneys is always damaged, hence it is a mistake in the opinion of this therapist, to give bromide to diabetics, especially when along with glycosuria there is albuminuria.

Grellety concludes that it cannot be too much remembered that there are conditions which render bromide of potassium almost a poison, and that before prescribing it, it is well to be certain that the remedy is not contra-indicated by the constitution, or the peculiar predisposition of the patient. The state of the lungs and the circulation, of the skin, of the digestive tube, and of the kidneys, is to be taken into account before the treatment is prescribed. In patients who perspire little, or whose renal functions are badly performed, bromide should be interdicted altogether.

#### MEDICAL NOTES.

—The *American Analyst* publishes a list of "thirty-nine articles" non-theological, which it obtained from a member of the White-house family, these articles having been recommended, epistolarily, by sympathiz-

ing friends, during the President's late illness with rheumatism. Of course many of these are patent medicines, and others homœopathic remedies, mostly in high dilutions. Many of the others were external applications and included "crude petroleum, and equal parts of skunk oil, rattlesnake oil and camphor spirits."

—One hundred deer, inhabiting the famous Richmond Park, in England, have been killed by order of the official veterinary surgeon, as being infected with rabies. No cause for the disease, in the way of the bite of a dog known to have been mad, is clear, and the grounds for the diagnosis have not yet been given to the public.

—The duration of infectiousness in the acute infectious fevers is placed by Dr. Frederick Pearse (*British Medical Journal*), as follows: Measles, from the second day, for exactly three weeks; small-pox, from the first day, under one month, probably three weeks; scarlet fever, at about the fourth day, for six or seven weeks; mumps, under three weeks; diphtheria, under three weeks.

—Instances are occasionally coming under medical observation, of accidents from the explosion of "syphon-soda" bottles. Whether the casualties are most frequently due to a defect in the quality of the glass, or to the water being too highly charged with carbonic acid gas, or to both conditions combined, is not known. But some very ugly little wounds have been caused in this way.

—On the 17th of April, a memorial ceremony, in honor of the late Professor Schroeder, instituted by the Society for Obstetrics and Gynecology, was held in the Aula of the University of Berlin, at which were present Minister von Gossler, Ministerial Director Lucanus, the Professors of the University, and many others. Schroeder's widow with her nine children and a brother took the place of honor near the marble bust of the deceased, which was encircled by palms and evergreens. The ceremony began with the singing of the choral, "Herr Gott Du bist unsere Zuflucht für und für," after which the memorial address was given by Privat-docent Dr. Löhlein.

—*Science* says that while the assumed fact that plumbers escape disease and infection from the inhalation of sewer-gas is often referred to as indicating the harmlessness of this air or gas, yet were all the facts known, this view would undoubtedly be much modified. A recent occurrence in England would seem to prove that men who follow this trade are not so exempt as is generally supposed. An inquest was held during the past month, in Liverpool, on the body of a plumber's apprentice who had been engaged during the previous week in repairing pipes which connected with a sewer. Quantities of gas came through these pipes, and at the time the young man complained of pain and sickness; in forty hours he died. The medical evidence was to the effect that death was due to the inhalation of sewer-air, and the jury rendered a verdict to that effect.

—The profession of medicine is so overcrowded in Germany, that the general union of physicians has sent a circular to all the directors of gymnasia urging them to dissuade their pupils from a career in which the chances of success are now so limited.

—The United States Consul, at Catania, in his dispatch to the U. S. State Department, dated April 8th, in reference to cholera, states "I am now glad to be able to report that the malady has ceased. The disease was first declared to be cholera on the 28th of February last. Soon after quarantine was established against the island of Sicily by the government of Italy. The people were greatly alarmed, and those who could get away fled. . . . At no time did the disease assume alarming proportions. The greatest number of cases reported in any one day was only seven. The disease seemed to be without epidemic features. The cause was attributed to the water of the wells, which was declared to be infected. The municipal authorities ordered the wells closed. The aqueduct for conducting water to the city from the slopes of .Ætna was completed by the 15th of March . . . and after the 22d of March no more cases of cholera were officially reported. The whole number of cases officially reported was eighty-three, and the number of deaths fifty-one."

The United States Consul, at Callao, in his dispatch dated April 1st, encloses copies of cable messages from Chili, showing that the ravages of cholera in that republic have almost ceased.

—Quarantine officers are warned by the Supervising Surgeon-General, Marine-Hospital Service, against admitting vessels from South America or the West Indies, except on the most rigid scrutiny. The bureau is informed that in two instances vessels have left an infected South American port (and one of these vessels had cholera on board) and put into a West Indian port without quarantine detention. Such vessels usually do not take bills of health.

—The circuit court sitting at Lebanon, Ohio, May 4th, in the case of Dr. Darby against the State, brought up on error, affirmed the decision of the court of common pleas. It will be remembered that the doctor was imprisoned and fined some months since for refusing to testify as an expert in a certain case unless guaranteed the fee of an expert, and the action created an absorbing interest among the medical fraternity throughout the country. The circuit court upheld the decision of that of the common pleas upon technical grounds, and without touching the important question as to whether a physician could be compelled to testify as an expert without receiving the fees of an expert. The fact that the doctor voluntarily attended the examination by the coroner, made him liable to summons as a witness, in the opinion of the court, without regard to whether his evidence should be in the nature of a knowledge of facts or of a professional opinion. The attorneys for the doctor except to the decision, and will carry the case to the Supreme court.

## BOSTON AND NEW ENGLAND.

—The recent course of lectures on the "History of Medicine," delivered by Dr. J. S. Billings before the Harvard Medical School, was well attended by physicians as well as by students, and proved of much interest. There are reports that Dr. Billings may be heard before the Lowell Institute on a similar subject next winter. While in Boston he also gave two lectures to the students of the Institute of Technology.

—The Committee on Education of the Massachusetts Senate, have reported a resolve granting \$100,000 to the Massachusetts Institute of Technology, provided that institution shall secure an equal sum in addition to its present property before December, 1887, when the first half of this grant becomes payable. In consideration of the grant the institute is required to maintain twenty free scholarships, and each senatorial district in the State shall once in eight years, in such alternate order as the Board of Education may determine by lot, be entitled to one scholarship for a period of four years, preference being given to candidates otherwise unable to bear the expense of tuition. In case no candidate appears from a senatorial district, a candidate may be selected from the State at large.

—The Committee on Charities has recommended a grant of \$10,000 to the Carney Hospital, South Boston, and \$10,000 to the Baldwinville Cottage Hospital for epileptics.

—Springfield, Mass., has raised \$130,000 for a General Hospital.

—About fifty cases of a fever, presenting in general most of the characteristic symptoms of typhoid, have occurred among the emigrants recently landed in Boston, from the Allan line steamship *Prussian*. There were several cases on the steamer during the voyage.

—The full bench of the Supreme Court of Massachusetts gave an important decision May 13th, in the suit of Samuel P. Train, *et al. vs.* the Boston Disinfecting Company, holding that a lien exists upon rags for charges of disinfecting when so ordered by the board of health. This was a suit of replevin to try the title to a lot of rags which had been disinfected by the defendant by the order of the board of health for this city, under their well-known regulation of June 15, 1885, since rescinded. The defendant claimed a lien for its charges. The plaintiffs, who are importers of rags, in December, 1885, entered into an agreement with the defendant, whereby the defendant was to disinfect all rags which the said board of health might order to be disinfected at ten per cent. discount from the regular rate of \$5 per ton on the first 500 tons of rags disinfected; fifteen per cent. discount on the first 1000 tons and upward; that the lighterage charges should be deducted from the amount of discount allowed, etc. It also appeared that the rags in suit were imported February 18, 1886, and were ordered by the said board of health to be disinfected by the defendant at the said works, and were received by the defendant for disinfection in accordance with the said order, and were disinfected at or about said date under

a protest by the said plaintiff, in the form of a letter to the board of health, in which the plaintiff says: "In view of all this, and the absence of any evidence or cause to suspect the said goods of infection, we hereby respectfully request of you a permit, duly authorizing the landing of the same, such as we are obliged to produce at the custom-house, under treasury department circular of June 1, 1885, and we respectfully protest against your requiring those rags to undergo any process of disinfection which shall put upon us delay and expense, because the rags are not infected, nor is there any cause to suspect them of infection. But if, notwithstanding, you require these rags to be submitted to some process of disinfection, we respectfully protest against your turning them over to the Boston Disinfecting Company, to be treated by them according to the process heretofore applied by that company to former importations of ours, for the following among other reasons: Because the process of alleged disinfection, as applied by them heretofore, is worthless as a disinfectant of the rags (supposing them to be infected), as adequate and proper tests will clearly show." In overruling the plaintiff's demurrer to the defendant's answer and ordering judgment for the defendant, the court says: "It was competent for the board of health to make the order by which the plaintiff's rags were subject to disinfection, and to impose the expense thereof on the plaintiffs and to subject the rags to a lien thereof."

## NEW YORK.

— During the week ending May 14th, there were reported eleven new cases of small-pox, and five deaths from the disease.

— At a meeting of the Society of Medical Jurisprudence and State Medicine, held May 12th, Professor Jarvis S. Wight, of the Long Island College Hospital, read a paper on the "Legal Responsibility of Surgeons." In the discussion which followed it was the universal sentiment that trials of cases involving questions of this kind should be heard only before juries composed of medical men.

— The untimely death of Dr. E. Darwin Hudson, is a serious loss to the profession. He was cut off by an attack of pneumonia of only a few days' duration, and no man of his years, in the city, had acquired a more enviable reputation as a consultant and clinical teacher; while his character was such as to make him widely beloved and respected. He was graduated from the College of Physicians and Surgeons in 1867, and at the time of his death, (which occurred May 9th, at the age of forty-three years), he was Professor of General Medicine and Diseases of the Chest, in the New York Polyclinic, and Attending Physician to Bellevue and St. Elizabeth's Hospitals.

— The Annual Commencement of the College of Physicians and Surgeons, the medical department of Columbia College, was held at Steinway Hall, May 12th, when degrees were conferred upon 106 graduates. The first Harsen prize of \$500, for proficiency

in examinations was awarded to Ellsworth Eliot, Jr., and the Cartwright Alumni Prize of \$500, for the best medical essay, open to universal competition, to Dr. B. Farquhar Curtis, of New York; subject, "Injuries to the Abdomen and Rupture of the Intestines." Drs. J. Gardner Smith, of New York, and Hobart Ham, of Philadelphia, received honorable mention for their essays. The address to the graduating class was delivered by Gen. Stewart L. Woodford, who said that he wanted all the alumni of the college to feel it their duty in the future years to assist Columbia in the development of the true idea of a university.

## Correspondence.

## A LONG OBSTETRIC RECORD.

PLATTSBURGH, N. Y., May 11, 1887.

MR. EDITOR.—The following "Obituary," taken from the *Vermont Centinel*, of June 4, 1806, published at Burlington, Vt., may interest some of your readers:

"At Somers (Con.) the Widow Mary Sexton, in the 91st year of her age. She practiced Midwifery fifty-five years, and by her records she was at the birth of 3,500 children; was the mother of 11 children, nine of whom are living; grand children and great grand children 121 living to mourn their loss." Yours truly,

D. S. KELLOGG, M.D.

## A SUGGESTION FOR THE PREVENTION OF SEA-SICKNESS.

HARVARD COLLEGE,

CAMBRIDGE, MASS., May 12, 1887.

MR. EDITOR.—Some years ago, whilst studying the feeling of dizziness, I was led to discover the singular immunity from it which deaf mutes, as a class, possess; and in an article published in the *American Journal of Otology*, for October of that year, I ascribed this immunity to the destruction either of the auditory nerves or of their labyrinthine termination. I found, moreover, in deaf-mutes what seemed signs of a possible immunity from sea-sickness; and ventured the suggestion that the semi-circular canals were probably the starting-point of that affection also, and that its symptoms in an ordinary sufferer might perhaps be alleviated by blistering or otherwise counter-irritating the skin around the ears. Later, I thought, that in crossing the English Channel I had prevented an attack of sea-sickness in myself by simply rubbing my mastoid processes with my fingers. I have been unable to get any one else (such is the inertia of the human beings amongst whom our lot is cast!) even to try the experiment—which I should think might succeed in a short voyage even if it failed in a long one. Later, a New York physician (whose pamphlet I have mislaid, and whose name I am ashamed to say I cannot momentarily recall) defended the same theory in a very interesting manner, and, if I remember aright, drew from it similar therapeutic consequences. My present object in writing is to take advantage of a newspaper article which has been sent me, to bring the matter once more before the attention of the profession, and to stimulate experimentation, if possible. The editor of the *Gulf View*, of Cedar Key, Florida, in the number for April 2d, of that Journal, gives the following interesting account of his own case:

"In the year 1859 he received a blow from behind on the mastoid process, just behind the right ear, crushing the outer table of the skull and destroying the delicate nervous portion of the internal ear, including these same semi-circular canals, alluded to, as being absent or negative in deaf-mutes. The immediate consequences of the injury

were, first, the most distressing nausea of a character identical with that of seasickness, which lasted with intervals of ease for two or three days, and secondly, complete destruction of the function of the organ, the ear of that side being totally dead ever after. Shortly after convalescence, the writer made a voyage to Cuba and back, in rough weather, exposed to a very rough sea for six days on the voyage over, and the same time returning, and to his agreeable surprise, though previously very susceptible, he found himself to be proof against seasickness, and the immunity has continued to this day, nearly, twenty-eight years."

This editor adds, having seen some chance allusion to my suggestion in another paper, that, "It would be queer, if from these incidents and inductions, we should arrive at a knowledge of a sure means of obviating the horrors of

the *mal du mer*, which seems not improbable, and the suggestions made by Dr. James of the use of friction, or counter irritation as a remedy, is surely worthy of careful and extended trial, coupled with such other remedies as our improved knowledge of the causes of the disease may suggest. We shall await the result with interest."

Will not you and other leaders of opinion give publicity to this subject and urge travellers to try so simple an experiment? The yachting and travelling season is about to begin. It would seem, if public attention were well attracted to the matter, that by next autumn we ought to have enough cases of trial either to prove or to disprove what at present remains a mere hypothesis. I need not say how glad I should be to receive information either of distinct failure or distinct success.

Very truly yours,  
WM. JAMES.

## REPORTED MORTALITY FOR THE WEEK ENDING MAY 7, 1887.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from				
				Infectious Diseases.	Acute Lung Diseases.	Diarrheal Diseases.	Diph. & Croup.	Measles.

Deaths reported 2,538; under five years of age 843; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fevers) 354, consumption 337, lung diseases 353, diphtheria and croup 102, diarrheal diseases 64, measles 61, typhoid fever 33, scarlet fever 26, cerebro-spinal meningitis 17, malarial fever 16, erysipelas 12, whooping-cough nine, puerperal fever seven, small-pox (New York) seven. From typhoid fever, Philadelphia 12, Boston five, Pittsburgh three, Baltimore and Milwaukee two each, New York, District of Columbia, Nashville, Fall River, New Bedford, Somerville, Salem, Holyoke and Newton one each. From scarlet fever, New York 14, Philadelphia three, Boston two, Taunton four, Pittsburgh, Milwaukee and Holyoke one each. From cerebro-spinal meningitis, New York eight, Philadelphia and Fall River two each, District of Columbia, Milwaukee, Cambridge and Worcester one each. From malarial fevers, New York and New Orleans, five each, Philadelphia, Baltimore and District of Columbia two each. From erysipelas, New York eight, Philadelphia two, Boston and Milwaukee one each. From whooping-cough, New York three, Baltimore two,

Philadelphia, Boston, District of Columbia and Pittsburgh one each. From puerperal fever, New York and District of Columbia two each, Philadelphia, Milwaukee and Nashville one each.

In the 17 cities and greater towns of Massachusetts, with a population of 895,741 (population of the State 1,941,465) the total death-rate for the week was 22.46 against 22.44 and 24.38 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,245,029, for the week ending April 23d, the death-rate was 21.6. Deaths reported 3,825; infants under one year of age 893; acute diseases of the respiratory organs (London) 357; measles 291, whooping-cough 134, scarlet fever 47, diarrhoea 40, fever 24, diphtheria 21, small-pox (London) one. The death-rates ranged from 14.9 in Birkenhead to 26.4 in Manchester; Birmingham 23.4; Brighton 16.3; Hull 22.3; Leeds 22.7; Leicester 15.7; Liverpool 28.7; London 18.9; Newcastle-on-Tyne 20.6; Nottingham 15.8; Sheffield 22.8; Sunderland 26.6.

In Edinburgh 20.0; Glasgow 25.4; Dublin 31.3.

The meteorological record for the week ending May 7, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending Saturday, May 7, 1887.	Barom- eter.	Thermometer.		Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 7, 1887, TO MAY 13, 1887.

ALEXANDER, C. T., lieutenant colonel and surgeon. Granted leave of absence for four months, with permission to go beyond sea, to take effect May 23, 1887.

HARVEY, P. F., captain and assistant surgeon. Granted leave of absence for four months, with permission to go beyond sea, to take effect June 10, 1887. S. O. 105, A. G. O., May 7, 1887.

BIART, VICTOR, captain and assistant surgeon. Ordered for examination by Army Retiring Board at Fort Leavenworth, Kan. S. O. 107, A. G. O., May 10, 1887.

ELBRIE, F. W., captain and assistant surgeon. Ordered for examination by Army Retiring Board at Washington, D.C. S. O. 109, A. G. O., May 12, 1887.

#### SOCIETY NOTICES.

ANNUAL CONGRESS OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION.—The Ninth Annual Congress of the American Laryngological Association, Academy of Medicine, New York, May 26, 27, and 28, 1887. May 26th. Morning Session at ten o'clock. Roll-call. Reception of Guests, etc. President's Address. Reading of Papers. Evening. Theatre Party (Casino) and Supper (Delmonico's) by invitation of Dr. George M. Leferts. May 27th. Morning Session at ten o'clock, promptly. Business Meeting: Open to Fellows of the Association only. At eleven o'clock, the doors will be opened and the reading of Papers commenced. Afternoon Session at three o'clock. Discussion. Evening. Annual Dinner of the Association at Delmonico's at seven o'clock. May 28th. Morning Session at ten o'clock. Reading of Papers. Afternoon Session at two o'clock. Reading of Papers. Election of Fellows. Ballot for Officers, 1887-8, and their induction into office. Adjournment.

D. BRYSON DELAVAN, M.D., Secretary.

INTERNATIONAL CONGRESS ON INFEBILITY.—The Council of the English Society for the Study and Cure of Infertility, have completed arrangements for an International Medical Congress, to be held at Westminster Hall, London, July 5, and 6, 1887. The object of this Congress is to present and discuss the problems of Infertility Medically, and from a purely scientific standpoint, by the best authorities, thus laying the foundation for a broader and more exact study of this subject. Papers and addresses are promised from a large number of the most distinguished Physicians.

T. D. CROTHERS, M.D.,

Chairman American Committee.

ASSOCIATION OF AMERICAN PHYSICIANS.—The Second Annual Meeting of the Association of American Physicians will be held in the Army Medical Museum Building, at Washington, D.C., June 24 and 25, 1887. Sessions at 10 A.M., 2-20 P.M., and 8 P.M.

GEORGE L. PEABODY, M.D., Secretary.

57 West 38th Street, New York.

THE AMERICAN CLIMATOLOGICAL ASSOCIATION.—The next annual meeting will be held in Baltimore, May 31st and June 1st, 1887.

J. B. WALKER, M.D., Secretary.

1617 Green Street, Philadelphia, Pa.

MASSACHUSETTS MEDICAL SOCIETY. One Hundred and Sixth Anniversary.—The Annual Meeting will be held at 9 o'clock, A.M., Wednesday, June 8, 1887, in Huntington Hall, at the Institute of Technology, Boylston Street (between Berkeley and

Clarendon), Boston. The usual arrangements have been made for the preceding day, Tuesday, June 7th.

FRANCIS W. GOSS, M.D., Recording Secretary.

BOSTON, May 9, 1887.

TUESDAY, JUNE 7, 1887, 10 o'clock, A.M.—The Fellows of the Society are invited to visit the Massachusetts General Hospital, on Blossom Street; the Boston City Hospital, on Harrison Avenue; and the Children's Hospital, on Huntington Avenue.

2 o'clock, P.M.—Meeting in Huntington Hall. Papers will be read as follows: "Tumors of the Bladder," by George W. Davis, M.D., of Holyoke. "Cases of Burns, with special reference to Complications, Sequelae and Treatment," by James E. Cleaves, M.D., of Medford. "Laparotomy for Pus in the Abdominal Cavity and for Peritonitis," by John C. Irish, M.D., of Lowell. "Fracture of the Spine: its Immediate Treatment by Rectification of the Deformity and Fixation by Plaster-of-Paris Jacket," by Herbert L. Burrell, M.D., of Boston. "Observations on the Puerperal Pelvic Ligaments," by Stephen W. Driver, M.D., of Cambridge. "The Relation of Tea Drinking to Disorders of the Nervous System," by William N. Bullard, M.D., of Boston. "Pulmonary Tuberculosis as a Sequel to ordinary Pleurisy with Effusion," by Herman F. Vickery, M.D., of Boston. "The Surgical Treatment of Chronic Empyemas," by Maurice H. Richardson, M.D., of Boston.

EXHIBIT.—At the Institute of Technology, during Tuesday and Wednesday, there will be an exhibition of official pharmaceutical preparations, instruments, surgical appliances and apparatus.

WEDNESDAY, JUNE 8, 1887, 9 o'clock, A.M. The One Hundred and Sixth Annual Meeting.—I. Secretary's Report and Report. II. Treasurer's Report. III. Medical Papers and Communications: "A Contribution to the Study of the Etiology of the Summer Diarrhoea of Infants," by Henry C. Haven, M.D., of Boston. "Septic and Antiseptic in Summer Diarrhoea," by S. Allen Potter, M.D., of Roxbury. "Training Nurses," by Alfred Worcester, M.D., of Waltham. "The Value of Public Health Measures to the State," by Samuel W. Abbott, M.D., of Wakefield. IV. Introduction of Delegates. (Intermission of fifteen minutes).

12 o'clock, P.M.—The Annual Discourse, by George J. Townsend, M.D., of South Natick. The hall doors will remain closed during the delivery of the discourse.

1 o'clock, P.M.—The Annual Dinner will be served in the Skating Rink, on Clarendon Street, near Boylston, to which place the Fellows, called in order of seniority, will walk in procession.

COUNCILOR'S MEETINGS will be held during the ensuing year at the Medical Library, No. 19 Boylston Place, Boston, as follows: I. The Annual Meeting, at 7 o'clock, P.M., Tuesday, June 7th. II. A Stated Meeting, at 11 o'clock, A.M., Wednesday, October 5th. III. A Stated Meeting, at 11 o'clock, A.M., Wednesday, February 1, 1888.

THE ANNUAL CONFERENCE OF CENSORS will be held at 2.30, P.M., Tuesday, June 7, 1887, at the Medical Library, No. 19 Boylston Place, Boston.

CENSOR'S MEETINGS.—The Censors for Suffolk District, officiating also for the State Society, will meet in Boston, for the examination of candidates on Thursday, June 2, 1887, and on the Third Thursday of September and of December. But they cannot examine any candidate who is already a resident, or in practice, in any District other than Suffolk. Their meetings will be duly advertised in the *Boston Medical and Surgical Journal*. In the other Medical Districts the Censors will hold their meetings for the examination of candidates residing in their respective Districts, and none other, at the same place and on the same day as the stated meetings of the District Societies.

CASES OF MULTIPLE NEURITIS.<sup>1</sup>

BY CHARLES F. FOLSON, M.D.,  
Visiting Physician, Boston City Hospital.

ALTHOUGH primary, multiple, degenerative neuritis has been recognized and described for twenty years or more, very little attention has been given to the disease until within five years. The first cases fully recognized in Boston, or, at least, reported, so far as I know, were four years ago, when there was quite a number of idiopathic cases in this city, and the disease prevailed also in several stables, among horses.

Among the cases which I have seen there have been three types: (1) Idiopathic, in regard to which the opinion now prevailing is that the disease is of infective origin, analogous to beriberi. (2) Toxic. (3) Purely rheumatic, like Bell's palsy. I will describe only a few typical cases, alluding briefly to others.

C. R., a Swede, thirty-eight years old, married, a rigger and sailor, entered the Boston City Hospital, in my service, July 6, 1886. A week previous he was on deck, in an exciting yacht race, in his stocking-feet, and got his feet and legs thoroughly wet. In the evening he thought that he had taken cold. The next day his legs felt heavy, and he could not go aloft, but worked on deck. The following day he went home and took to his bed, complaining of severe pain in the small of the back, knees, ankles, and feet, moderate headache, loss of appetite, nausea, and excessive thirst. He had, also, a slight chill. He complained of a dead feeling in his legs, and said that he could not walk. He could not sleep from pain in his limbs and joints, and restlessness. Two days after the trouble in his legs his hands felt numb, and his arms were observed to be weak; and still two days later, he began to have difficulty in drinking, on account of inability to tightly close his mouth. He thought that his speech was altered, being somewhat thick. He had perspired excessively.

The patient was a strong, well-developed, and well-nourished man, without ascertainable hereditary predisposition to disease, a moderate drinker, and, according to his statement, without a previous history of syphilis.

On examination, there was no evidence of disease of the thoracic, abdominal, or pelvic organs, nor of the brain and spinal cord. Temperature was 99.4°, pulse 96, respiration 32. Tongue slightly coated, moist; protruded straight, but only as far as about one-quarter of an inch beyond the line of the teeth. The eyelids failed to close by about the space of one-half an inch, and the lips by one-quarter of an inch. No affection of the motor muscles of the eyeballs; pupils not abnormal. Speech decidedly thick, cheeks puffed out a little, eyebrows cannot be raised. The grasps of both hands were weakened and nearly equal. The arms could be moved freely, but not used. The legs could be moved only very slightly.

There was some sensation of prickling, very slight, in the feet, and a numb or "dead" feeling in hands and legs. Superficial sensation was somewhat impaired in the feet, and very slightly in the legs; elsewhere unimpaired, except for some cutaneous hyperaesthesia in thighs, arms, trunk, and face. No diffi-

culty in respiration. The disease was very nearly symmetrical; if any difference, the left side was slightly more affected than the right.

The urine was normal, of specific gravity 1026. The bowels were constipated, micturition normal, spleen not manifestly enlarged; no pain or swelling in any joints. On lying still in bed, there was no pain anywhere, but motion of the legs was painful, and pressure, even moderate, over the nerve-trunks, and in the course of the nerves in the legs and thighs, gave rise to exquisite pain. There was no evident muscular atrophy. The chin-arm and knee-jerks were absent, and there was no response from the plantar, epigastric, and abdominal muscles; very slight from the cremasteric.

In the course of the disease, the pain became so extreme that subcutaneous injections of morphia and laudanum externally were used freely for three months. The tenderness on pressure over the course of the nerves, from the shoulders down, became everywhere excessive. There was also great pain in opening and closing the jaws, and tenderness on pressure over the motor branch of the fifth pair. The paralysis gradually reached a point where the patient could not turn in bed from his back to his side, or move his legs. The fingers closed only faintly in the motion of grasping. The wrist-drop was not very marked. The paralysis of the extensors of the feet was absolute, so as to require the use of foot-splints. There was extreme loss of flesh in the legs, and generally considerable quantitative lowering of electro-muscular contractility, and, finally, lack of response in extensor muscles and some others to either current, faradic or galvanic. The bowels became most obstinately constipated. There was troublesome retention of urine, but not sufficient to require the catheter. There was also a small bed-sore.

The mental condition was of a mild stupor, approaching delirium, to the extent that, for a few weeks, the patient's statements with regard to anything which had happened several hours previously could not be depended upon. The aspect was distinctly typhoidal. The spleen was not found to be enlarged at any time. A very mild degree of anaesthesia, just noticeable, extended, in time, over the thighs, trunk, and arms, and it increased in the legs and feet.

At the end of the first month the tongue was nearly clean, and slight improvement was observed in the hands and face.

At the end of the second month, the patient could move his arms pretty well and close his fingers in a grasp, but not exert force. He had very little trouble in eating, as he could close his lips, and there was no pain in chewing. There was some tenderness on pressure over the motor branch of the fifth pair, but scarcely any over any of the nerves of the arms, chest, trunk, abdomen, or thighs, but excessive over those of the legs. He could almost close his eyes, and could move from side to side, but not sit up. There was no soreness on motion, but the pain in the legs still required opiates, especially at night. The flexor muscles of the forearm reacted to the faradic current; the extensors, the quadriceps femoris, and all of the leg to neither current. Massage was begun, and, three weeks later, galvanism, beginning where extreme tenderness on pressure had disappeared, galvanism following massage, until both were gradually extended over the whole body.

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology and Hygiene, of the Suffolk District Medical Society, April 13, 1887.

At the end of the third month, marked and steady improvement had been observed everywhere, except in the legs. There was complete ankle-drop; and the muscles of the thighs and arms, but especially of the legs, were very much wasted, soft, and flabby. There was still great tenderness on pressure over the calves, but there seemed to be no well-marked diminution of sensation, except in the feet, and that not very great. Two weeks later he was sitting up daily, and in another week there was scarcely any tenderness anywhere on pressure in feet or legs.

A little after the close of the fifth month, the foot and toes were seen to move, for the first time, on the right side, and the tibialis anticus and gastrocnemius muscles contracted. In a few days, similar observations were made of the left foot and toes; but, at the end of the sixth month, he was still unable to stand. A week later he began to walk, with support, and two weeks after that he could walk alone. Two weeks later still, he was discharged at his own request, that is, about a week after the seventh month of treatment. All the muscles, at that time, reacted to galvanism, although in degree considerably below the normal in the legs and feet, less so in the arms. He could raise his feet and toes, although they dropped somewhat in walking.

At the end of the ninth month he had regained his usual flesh, and, except in his legs, he said, his usual strength. He could walk perfectly well on a level, but, going up or down stairs, or over curbstones, needed a cane or some similar support. I found him, after some difficulty, on the street, and could not make a full examination. The knee-jerks were still absent, but the patient expects to go to work soon.

In accordance with my previous experience in such cases, I found very little benefit from salicylic acid or the salicylates in treatment, but the pain always diminished after using quinine in full doses.

As regards diagnosis, the muscular wasting and electrical reactions exclude Landry's paralysis, which is, I believe, now accepted to be a rapidly fatal form of myelitis; the gradual invasion of one group of muscles after another, with sensory disturbances, and the pain and tenderness on pressure, exclude anterior poliomyelitis, and no other diseases would suggest themselves. After admission to the hospital, the temperature did not exceed 100° F., nor the pulse 102. But the febrile symptoms, and typhoid appearance and mental condition, place the case among the infective diseases, and, therefore, in the first group of idiopathic, primary, multiple, degenerative neuritis.

Although there was a previous history of exposure to wet and cold in this case, there has not been such in my other cases. Judging from previous experience, the prognosis in this case seems to me favorable for the reappearance of the knee-jerk and ultimate greater improvement, if not entire restoration of function in the legs, but probably not for some months, and possibly, not within a year or two.

I have not been able to make out any distinct enlargement or hardness of any of the nerves in these cases. Indeed, the exquisite pain prevented an examination careful enough to settle these points.

Of the toxic cases, I am not sure that I have ever seen arsenical multiple neuritis. At least, the diagnosis was not confirmed, or otherwise, by chemical examinations of the wall-paper or urine. Those due to lead are readily diagnosed by the usual methods

of testing for its presence in the urine. A previous history of syphilis, especially after a rapid relief by mercury or iodide of potassium, of course, justifies the assumption that the case is syphilitic. Cases after the infective-diseases, especially typhoid fever and diphtheria, are reported, and have been probably seen by most of us. In the course of chronic disease of the lungs and kidneys, especially in the late stages, they are not very uncommon. One of the most distressing forms of multiple or general neuritis, and perhaps the most hopeless, is due to the long-continued abuse of the preparations of opium. Where it exists the abandonment of the opium habit and its continuance are so nearly equally painful and fatal that there is little choice between them. By far the most frequent source of toxic general neuritis, however, is alcohol; and cases occur in all degrees of severity, of which I shall report two, one at each extreme.

Mr. —, a literary gentleman, just beyond middle age, born in Europe, came to this country with the habit established of drinking a pint of claret with his dinner. Under the press of heavy work, he increased his pint of claret to a quart, and drank a half-tumbler of whiskey at bed-time. He also used tobacco freely.

On account of some failure in eyesight, not excessive, impaired facility of using the legs, which was troublesome in going up and down stairs, etc., but otherwise not considerable, a dull pain in the thighs and legs, disappearance of the knee-jerks, and marked swaying of the body with the eyes closed, the confident diagnosis of locomotor ataxia had been made. There were some slight anesthesia and parasthesia. I could not find any symptoms that seemed incapable of explanation from the alcoholic history, although the patient had never been intoxicated in his life and had never been conscious of taking alcohol to excess. There was some, though slight, tenderness on pressure over the course of the nerves in the legs. The alcoholic habit was given up; in a year the knee-jerk had re-appeared and the symptoms suggesting the diagnosis of posterior spinal sclerosis were gone. This mistake is, I think, a not very infrequent one, and occurs, too, in multiple neuritis due to syphilis or lead. I have also seen cases of locomotor ataxia where there seemed to me to be symmetrical peripheral neuritis, to the relief of which I attributed great temporary improvement in the symptoms.

M. H., single, twenty-six years old, employed in a bar-room, entered the Boston City Hospital, August 12, 1886. His father died of rheumatic fever. Eight years previous to admission patient had typhoid fever and once fell unconscious in a fit after drinking heavily. He had been a hard drinker for many years, and for a week past had been sleepless and without appetite, drinking steadily. After sleeping in a cellar, drunk, he awoke with severe pains in his head, back, and entire left side.

On entrance he appeared well developed, and fairly nourished. Temperature 100.4°, pulse 104, respiration 28. Tongue rather dry, slightly coated. Bowels constipated. Urine, a trace of albumen. The examination of thoracic, abdominal and pelvic organs was negative.

Pupils of moderate size, right somewhat larger, both react fairly well; marked nystagmus on looking to either side; motion of left eye outward somewhat limited. Some tremor of fingers, left grasp weaker than right. Coördination good. Sensation unim-

paired in head, arms and trunk. In both legs below knee are one or two areas of diminished sensation. Left knee-jerk nearly, if not quite absent; right very weak. Superficial reflexes well marked. Slight tenderness along nerve-trunks in both legs and right thigh, possibly somewhat in forearms. Mental condition not remarkable.

13th. Increase of pain in arms, legs, chest and abdomen. Marked tenderness over course of nerves in legs, arms and intercostal spaces. Complaints of numbness in hands, but there is no diminution of sensation. Both grasps distinctly weak. Considerable loss of power in extensors of feet and toes. Knee-jerks absent.

14th. Last night became very delirious and actively violent, requiring restraint, and during which he became unconscious of pain or tenderness. Somewhat quieter this morning, but still delirious and constantly talking. Excessive muscular tremor. Takes nourishment fairly well.

15th. In a mild semi-delirious state, picking clothes, etc.; very weak, with feeble pulse. Extreme sensitiveness to pressure over course of nerves everywhere but in the head and neck; screams with pain with the least touch or movement of the body and limbs.

16th. Is still quite delirious, complaints of soreness and pain all over; marked anaesthesia especially in legs.

21st. Marked loss of power in legs and some in arms. Toes drop. Over both buttocks are abrasions of skin, superficial, size of dollar. Urine and faeces passed in bed. Mental condition quite suggestive of the final stage of general paralysis.

25th. Loss of power in arms and legs seems greater.

28th. Complete wrist- and toe-drop. Is more delirious, the delirium frequently being of a tearful and painful character; often shouts in imaginary conversation. Eats well. Extreme sensitiveness on pressure over the nerves; muscles very flabby, with very little power of movement in muscles of arms, legs and trunks.

September 2d. Constant hallucinations of sight and hearing. Has no idea where he is, and most of the time recognizes no one about him; has been seen to put faces in his mouth. Cannot turn over in bed without help.

5th. Bed-sore over right buttock, irregular in outline, superficial, about two inches in diameter. Small abrasion over left buttock. Habits very filthy. Distinct nystagmus noted at times. Sleeps but little.

8th. Can now turn himself in bed and feebly extend right wrist. Mental condition no better. Sleeps poorly. Takes any food given him.

18th. Is delirious all the time when awake, and thinks he spends his time in the woods, down by the wharves, and on long walks in the country. Last night restless and noisy, and rolled out of bed. Cannot walk on hands and knees.

23d. Less noisy. Bed-sores improving.

29th. In general, seems to be improving somewhat.

October 6th. Is able to extend right wrist slightly. Grasps very weak, but growing stronger. Still marked sensitiveness over nerve-trunks, especially in legs. Feet completely dropped, but there is some power of voluntary motion in toes. Very marked general wasting; flabbiness of muscles. Mental condition decidedly better; eats and sleeps well without opiates. Can turn in bed. Anaesthesia very moderate and chiefly in the feet and lower part of legs.

13th. Quieter and more rational; eats and sleeps well.

17th. Memory extremely poor, but shows no delusions.

22d. In general, is improving physically and mentally, and in good spirits.

27th. Gaining both in motion and sensation of extremities. Tenderness over nerve-trunks much less.

31st. Still some tenderness over nerve-trunks. No evident impaired sensation. Knee-jerks absent. Feet and toes dropped, but both can be moved and raised a little. Grasps weak but about equal. Elbow-jerks present. Muscles of limbs thin and very flabby.

November 24th. Gradually gaining; still considerable tenderness in legs and pain on motion. Some motion in both feet and toes.

December 21th. Improvement continues; can walk a few steps without assistance.

January 10th. Quite comfortable; complaining of some pain in lumbar region and left hip. Otherwise pain and tenderness on pressure gone.

16th. Improving rapidly, is up and dressed daily, and can walk quite well. Muscles react fairly well to galvanism.

18th. Discharged at his own request, and I have not been able to learn anything of him since that time.

The treatment in this case consisted of rest in bed, abundant food, opiates very freely, the actual cantry and small blisters over the course of the most painful nerves, and, later, after the soreness on pressure had nearly disappeared, massage and galvanism. The reaction to both currents in this case was decidedly diminished, but the reaction of degeneration was not found.

As illustrations of what I supposed to be purely rheumatic cases, and, perhaps, throwing some light on the question of pathology, I will very briefly report two cases:

The first was of a young man, who got drunk, lost his way, and slept in the woods in the snow, his shoulders having been particularly exposed. On awaking, he had severe pain in his shoulders and arms, which gradually increased, so as to become most intense, and increased by motion of the arms, with tingling and numbness in the hand and fingers. There was almost entire paralysis when I saw him, a few days later, diminished reaction to the faradic current, and extreme tenderness on pressure over the nerve-trunks. With rest, warm anodyne fomentations, quinine in large doses, and later, rubbing and electricity, there was complete recovery in six weeks.

The second was a young carpenter in Newport, kindly sent to me by Dr. Engs, of that city. After working all the afternoon, wet through in a cold rain, he spent the evening with his wet shirt on, after having changed his other clothing. The next morning he had severe pain in his arms, which soon increased to a degree which was quite excruciating, and lasted for several weeks. Whether there were other sensory symptoms or not then, I could not ascertain: I saw him three months later, and found marked atrophy and extremely limited power of motion in both shoulders and arms. The pain had subsided so as not to be especially troublesome, and there was not marked tenderness on pressure over the nerve-trunks. There was some reaction to the faradic current, and no marked sensory disturbance, that is to say, inflammation had subsided, and processes of recovery or of degeneration were to begin.

At the time of the examination, the patient's condition might have been explained by a diagnosis of an-

terior poliomyelitis; but, with the history, considering it a case of neuritis, I gave a favorable prognosis. He was sent to the Massachusetts General Hospital for convenience of treatment, and in three months returned home somewhat improved. He gained steadily at home, and when I saw him, a year later, there was scarcely any atrophy of the arms, and he had very good use of them. His hands were still not sufficiently recovered to resume his trade, although he could use them freely in eating, dressing, and plain work. The extensors of the hand were mostly at fault, but as they were capable of contraction and some usefulness, I gave as a prognosis that, in a couple of years more, the patient would be likely to have quite useful hands, so as to be able probably to resume his trade.

The pathology of these various cases has not yet been so far investigated as to place it on an entirely substantial basis. That they have many features in common is evident.

So far as I am able to learn, post-mortem examinations in cases of primary multiple neuritis have not thus far shown disease of the brain or spinal cord, which has not been acknowledged to be insufficient to produce the symptoms, and in most cases there has been no central lesion found; the evidence being that the disease is primarily an interstitial peripheral neuritis, that in mild cases the disease goes no farther, and that in severe cases there is also parenchymatous inflammation, and more or less degeneration of nerve-fibres. Both processes are capable, in time, of a great degree of regeneration, or, at least, of restoration of function. The distinct sensory symptoms with which the disease is commonly ushered in usually soon nearly disappear, except pain and marked anesthesia is a rare exception in the disease. We are driven, therefore, to suppose (1) that there is an undiscovered central lesion; (2) that there is a functional central disease giving rise to the neuritis, as Erb holds; (3) that Leyden and Oppenheim are right that the central lesions thus far observed result from ascending neuritis, or form a part of the morbid process in the nerves, without giving rise in themselves to any special symptoms; or finally (4), with Strümpell, that primary multiple neuritis affects chiefly the motor fibres—a supposition analogous to Westphal's theory that the motor fibres or cells in the cord may be sensibly diseased without affecting those governing nutrition of the muscles.

Alcohol has an affinity, so to speak, whether from a common microorganism or not, for the brain and spinal cord, as well as for the nerves, and clinical evidence, supported by a certain number of autopsies, supports the theory that many, at least, of the cases of alcoholic and lead neuritis are complicated with more or less cerebral or spinal disorder, or both. That a central lesion, cerebral or spinal, may not ultimately be found to be a necessary factor in the idiopathic and other forms of the disease, of course, I am not prepared to say.

There are cases, also, doubtless, which are primarily subacute or chronic parenchymatous degeneration of the nerve-fibres, without marked symptoms, except loss of power, or impaired sensation. Perineuritis also occurs, and there are mixed cases.

There are now four cases of leprosy in Minnesota as against six in 1884.

#### FOUR HOSPITAL CASES.<sup>1</sup>

I. TUBERCULAR PERITONITIS, WITH PERFORATION OF THE ABDOMINAL WALL. II. CIRRHOSIS OF THE LIVER. III. HÆMOPHILIA. IV. TETANY.

BY F. C. SHATTUCK, M.D., BOSTON,  
Visiting Physician, Massachusetts General Hospital.

I. TUBERCULAR PERITONITIS; SLOUGHING OF THE UMBILICUS AND FISTULA.

P., TWENTY-FOUR years of age, entered the hospital, June 21st. A sister died of phthisis. About a year before entrance the patient began to suffer from attacks of abdominal pain, distension and tenderness, lasting five to ten hours, and relieved by bilious vomiting. These attacks recurred at intervals of about a month. The last was four weeks before entrance; he did not rally from it but felt poorly, lost flesh and strength, and had moderate diarrhoea much of the time. He had no cough or other pulmonary symptoms. Pulse 100.

Physical examination showed slight consolidation at the right apex without softening. In the umbilical region a rounded cake-like tumor with irregular surface, four inches in diameter, and apparently covered over by intestine, was felt. On the right side of the tumor and in the right iliac fossa, tenderness was marked. Diagnosis: tubercular peritonitis.

July 3d. The patient was evidently weaker. Moderate fever was constant with evening exacerbations. The abdomen was more distended, peritoneal crepitus could be felt; night sweats, occasional vomiting, and abdominal pain were noted. The scanty sputum was examined for bacilli with a negative result.

July 14th. Several days before this date it was noticed that the skin about the navel was getting red and edematous. On this date a small perforation took place through which with each inspiration was emitted offensive gas, on deep inspiration offensive greenish fluid; during the act of vomiting this fluid was ejected with force.

July 18th. The fistula gradually enlarged, and the patient was transferred to the surgical side.

July 19th and again on the 22d, dejections of normal consistency passed the rectum, the only discharges of any kind through that outlet between the appearance of the perforation and death, which took place July 28th, from exhaustion.

*Autopsy.* The right pleural cavity was obliterated by old adhesions, a few of which were also found on the left side. The apex of the right lung was thickened, shriveled and dense; on section, numerous small gray tubercles, and some pigmented fibrous tissue were seen. Throughout both lungs there were occasional cheesy patches, a half-inch or more in diameter, some of them partially softened, surrounded by deeply injected borders containing milium tubercles.

A fistulous opening through the umbilicus contained a drainage-tube entering the peritoneal cavity partially obliterated by old adhesions. This encysted cavity extended upwards beneath the right lobe of the liver, and downward on the right to the pelvis, containing masses of necrotic fat tissue (omentum), and several ounces of offensive fluid; it communicated with the rectum above the internal sphincter by an opening in the anterior wall half-an-inch in diameter. The intestines contained tubercular nodules and ulcerations, chiefly in Peyer's patches.

<sup>1</sup>Read before the Section for Clinical Medicine, Pathology and Hygiene, of the Suffolk District Medical Society, April 10, 1887.

The pathological diagnosis was then as follows: Chronic pulmonary tuberculosis, acute bronchitis, tubercular peri bronchitis, chronic tubercular peritonitis and enteritis, umbilical fistula, perforating ulcer of rectum.

The special reason for reporting the case is the comparative rarity of spontaneous perforation of the abdominal wall in tubercular peritonitis. The seat of the perforation was also somewhat remarkable, the strong fibrous structures of the umbilicus being completely destroyed.

## II. CIRRHOSIS OF THE LIVER; ASCITES ABSENT UNTIL A FEW DAYS BEFORE DEATH.

A widow, forty-nine years of age, entered my service October 9, 1886; she was the mother of nine children, the youngest thirteen years old. She had never had any special illness, but had overworked herself from time to time, and been obliged to go to bed for several days to rest. The past two or three years these periods of overstrain had been more frequent.

About three months before entrance she had an attack of "dysentery" with pain, bloody discharges, and tenesmus. The blood in the stools was quite abundant and persisted for three weeks; during the first week of her illness she vomited blood several times in considerable quantities; she was six weeks in bed. Since she got up there had been no recurrence of hæmorrhage; but the blood loss was not made up and she steadily lost in flesh and strength, and was entirely unfit for any work; nausea and vomiting after taking even small quantities of food, unattended by any pain, had been prominent symptoms. The two days before entrance vomiting was still more frequent, and she again passed blood from the bowels, but this time without pain and the blood in clots.

The patient was very anæmic, very slightly jaundiced, and the skin over the neck, arms, and body contained capillary dilations. The hepatic dulness was increased in width both upwards and downwards, and the edge of the liver was distinctly felt an inch and a half below the ribs; its surface was lacking in smoothness. The abdomen was distended with gas, but no ascites could be positively made out. The spleen was not enlarged. The urine contained a small trace of albumen and a few casts. A very loud systolic soufflé was heard over the heart, loudest in the pulmonic area; over the apex a thrill could be felt, but there seemed to be no enlargement of the organ. Diagnosis: cirrhosis.

October 10th. Passed a large blood clot and about 3iii. of fluid blood with fæces.

October 11th. There was now unmistakable ascites, the liver could no longer be felt, the diaphragm was pushed up, and there was slight œdema of the abdominal wall and feet. The vomiting continued from time to time, but there was no recurrence of hæmorrhages of any kind.

October 14th. The ascites had increased rapidly, and caused so much distress that she was tapped. After the withdrawal of the fluid the roughness of the liver surface was distinct, and the contour of the lower edge of the organ could be well made out. Considerable relief followed the tapping, but the patient gradually failed in strength and October 16th, six days after entrance, she died.

A full autopsy could not be secured, but my efficient house-officer, Mr. L. T. Stevens, succeeded in ex-

tracting the liver, in two portions, and some of the other organs through the rectum.

The heart was normal and showed no anatomical explanation for the very loud murmur heard during life. The lower portion of the ileum and upper part of the colon were full of black, tarry material. The liver was not materially altered in size and was eminently cirrhotic. The spleen was increased in density, though not in size. The kidneys showed moderate chronic interstitial changes.

It is a matter for regret that it was impossible to make the autopsy in the usual way. To remove the liver through the rectum it was necessary to cut it in half, and the precise condition of the portal vein and its main branches was thus impossible to make out. The extreme rapidity with which ascites appeared and progressed suggests the possibility of its dependence on thrombosis of the portal vein. The severe intestinal hæmorrhages showed that great portal congestion had existed for some months, and it also seems possible that in the occurrence of free bleeding is to be found an explanation of the late advent of ascites, the hæmorrhage relieving the stasis.

## III. HÆMOPHILIA.

H., a clergyman, fifty-two years of age, entered the hospital, July 12, 1886, for tonsillar abscess, of which he had had several previous attacks. The first was treated by incision, which was followed by hæmorrhage that did not finally cease until six weeks had elapsed. In a day or two after entrance the abscess broke, and the day after this he began to pass bloody and smoky urine, the source of which the microscope showed to be the kidneys. He reported that hæmaturia had followed each previous attack of parenchymatous tonsillitis, and was also brought on by unusual mental excitement or exertion. In all, he thought he had had as many as one hundred and fifty attacks. If he kept quiet, and drank large quantities of water, the bleeding generally ceased in five or six days, but if he worked, it lasted from twenty to thirty. When a child, slight knocks produced large, black-and-blue, painful swellings, which were slow to subside. When twenty-one years of age he had an epistaxis which threatened life, but bleeding from this source has never recurred. The tendency to bleed has, he thinks, diminished as he has grown older, but slight cuts are still followed by free and persistent hæmorrhage. No history of hæmophilia in either parent or grandparent could be obtained; all were long-lived. Of his seven brothers and sisters, one brother shows this tendency, and a sister's son exhibited the hæmorrhagic diathesis to a marked degree, finally dying of persistent hæmaturia.

Hæmophilia, like color-blindness and pseudo-hypertrophic paralysis, is transmitted through the females of a family, the females themselves generally escaping. The tendency can thus oftentimes be followed through many generations. My patient is an unusually intelligent man, and the fact that he cannot trace the diathesis behind his own generation is one reason for reporting the case.

## IV. A CASE OF TETANY (?)

A stable-boy, nineteen years of age, of good family and previous personal history, entered the hospital September 30, 1886. He was muscular, well built, and ruddy. He said that for the past year there had

been slight, but constant, stiffness of the jaw, which had not hindered speech or mastication, but had been sufficient to give him a constant desire of moving the jaw from side to side, and this had now become a habit.

The day before entrance, without any assignable cause or any warning, the stiffness of the jaw increased very much, the hands and forearms became numb and rigid; also the legs, to a less degree. This was soon followed by general tremor. The whole attack lasted some twenty minutes. During the attack he had a dull feeling in the back of his head, whence the numbness and stiffness seemed to start. There was no loss of consciousness or disturbance of vision. He had three such attacks yesterday, and two to-day. In the intervals between the attacks he felt perfectly well.

On entrance, the patient was in the midst of an attack, and was reported as having a chill. The temperature was 99.4°. By the time the house-officer reached him the attack had nearly passed, and his condition was as follows: He was much excited, free from pain, but complained of a disagreeable, indescribable sensation over the whole body. The pulse was rapid and strong, the breathing quickened. The expression of the face was peculiar, suggesting the *visus sardonicus*. The masseter muscles were hard to the touch; speech was difficult; there was marked stiffness of the arms and hands, the fingers being semi-flexed. Efforts to straighten the fingers encountered resistance, and caused slight pain. The legs were also somewhat rigid.

October 1st. I saw him for the first time. During the night he had had an abortive attack. Examination of the internal organs gave entirely negative results. As I finished testing the reflexes, which were not remarkable, an attack came on, preceded, for a few moments, by discomfort, slight mental excitement, and forced respiration. Stiffness then came on in the hands, arms, and fingers, which were all semi-flexed; the thumbs were held firmly between the first two fingers. The spasm was tonic, with slight tremor at times, and forcible attempts to counteract it caused pain. The mind was perfectly clear, and the patient was positive that he had no real pain, though decided discomfort was caused by the rigidity of the muscles. After fifteen or twenty minutes the stiffness disappeared entirely. Whether this result was furthered in any way by the inhalation of a little ether, I cannot say.

He was put on a full dose of bromide and chloral, every three hours, for several days. Slept nearly all the time, and had no more attacks, either spontaneously on testing the reflexes and the electrical reactions, or during pressure on the brachial artery and nerve. There was no increased electrical reaction of the muscles, the current being passed through the nerve.

October 9th. The patient was discharged, apparently well in every respect, except that slight stiffness in the jaw persisted.

The diagnosis seemed to involve the consideration of only three affections: tetanus, hysteria, and tetany.

The feature of the case which is chiefly suggestive of tetanus is the stiffness of the jaw, but this had been present for a year: this fact, with the absence of rigidity of the neck and back muscles, and the transitory character of the attacks, with entire freedom from symptoms in the interval, warrant us in excluding tetanus.

Hysteria is not so easily, and I do not feel that it

can be positively excluded, especially as Dr. Weir Mitchell, to whom I very briefly stated the case, thought it probably of that nature. But, apart from the attacks, there was nothing whatever about the boy to suggest hysteria. He dreaded the attack, as, indeed, do hysterical women oftentimes, for that matter. During the attacks he was perfectly reasonable, and he was glad to be discharged from the hospital. In the diagnosis of hysteria, the impression which the individual makes upon the observer counts for something, and this impression was, in the case before us, opposed to such a diagnosis. Moreover, the diagnosis tetany, in a mild form, explains very well the symptoms.

Tetany is a disease which is so rare with us — I can find no mention of it in Pepper's "System of Medicine" — that I may be pardoned for the following brief description of it: First described by Dance, who called it "intermittent tetanus," the term "tetany" was first applied to it by Corvisart, and later, adopted by Trousseau, who also called attention to its comparative frequency in nursing women. It is classed as a neurosis, affects young adults by preference, and is characterized by intermittent, tonic contractions, rarely of the trunk and face, most frequently of the upper extremities, and chiefly of the flexor muscles, the intellect always remaining clear. It is bilateral. The attacks are generally preceded by somewhat ill-defined prodromata, and recur at variable intervals during periods of a few days to months. In the intervals between the attacks, patients appear well. Trousseau first showed that attacks may be brought on at will by pressure on the nervous and arterial trunks, the spasm ceasing as soon as the pressure is relieved. Erb has shown that the muscles are stimulated with undue ease by means of electrical currents through the peripheral nerves. As long as these two phenomena are present, there is a liability to the recurrence of the attacks. Attempts to elicit the phenomena in my case failed, but the patient was already under the influence of chloral and bromide when the attempts were made — a fact which may or may not be of importance. The affection nearly always passes off without leaving any trace behind it.

After carefully considering all the facts in my case, I repeat that I am inclined to consider it as one of tetany of a fairly mild form, and very short course — three days. At the same time, I am far from wishing to suppress the points opposed to this diagnosis, namely, the trismus of a year's duration, and the failure to bring out the signs of Trousseau and Erb, on which the books lay considerable stress.

#### MYOSITIS UNIVERSALIS ACUTA INFECTIOSA, WITH A CASE.<sup>1</sup>

BY HENRY JACKSON, M.D., BOSTON.

I SAW last spring in Strassburg the following rare case, and though I had hoped to be able to give a more detailed account of the case, think that the few notes taken at the time, may be of interest to the members of the society. The above diagnosis, made by elimination during life, by Prof. Kussmaul, was sustained by the result of the autopsy performed by Prof. von

<sup>1</sup> Read at Section for Clinical Medicine of Pathology and Hygiene, of Massachusetts Medical Society, April 13, 1887.

Recklinghausen. The case entered the hospital May 18th, and was demonstrated in the clinic May 22d.

Woman, aged thirty-six; family history good; she has two healthy children; lives in a district apparently healthy; no one else sick in the house. Was never sick before so far as she knows.

Six weeks ago first felt sick (unwohl). Malaise, inability to work; had a red, papular eruption on the face, pain in the neck, pain in swallowing. She was treated for a sore throat. The eruption disappeared in a week's time without special treatment.

After the disappearance of the eruption, first noticed swelling, accompanied by pain in the shoulders, legs, and sacral region; the swelling in legs soon passed off, appearing in the arms. Last two weeks pain in the neck, swelling less marked. The pain, which was at first sharp, has become dull. Pain has always been in the muscles and not in the joints. Throughout the sickness appetite fair, thirst marked, sweating, moderate fever, constipation, no vomiting, urine scanty and high-colored.

On entrance, May 10th, slight fever, mind clear, slight oedema of face and extremities, muscles of extremities flexed and rigid; extension caused pain. Paresis of soft palate, electrical reaction in general diminished, reflexes absent. Examination of chest and abdomen negative.

During last few days high fever, rapid respiration, pulse 140. Several small patches of pneumonia.

Prof. Kussmaul considered the diminished electrical reaction as due, in part, at least, to the oedema, the abolition of the reflexes as of peripheral, not central origin; he considered the pneumonia as very probably due to particles of food which got into the lung on account of the difficulty in swallowing. Mind clear to the last; no symptoms pointing to disease of the abdominal organs. Death on May 24th; ultimate cause, broncho-pneumonia.

Trichinosis was first thought of; eliminated by the history (her husband did not allow her to eat raw sausages), by the absence of the gastro-intestinal symptoms as prodromata in this disease, by the fever in present case. Prof. Kussmaul said the case reminded him clinically of one in which thousands of miliary aneurisms were found all over the body.

The fever, the widespread muscular pain and oedema pointed to a diffused myositis without any discoverable local cause, hence the diagnosis was as stated.

*Autopsy, May 25th.* Brain and spinal cord presented nothing abnormal. Veins of abdominal cavity very full of blood. Spleen soft, enlarged. Stomach and intestines presented nothing abnormal.

Stricture at the entrance of the pelvis of right kidney into the ureter, which had caused hydronephrosis of right kidney with almost total disappearance of the substance of the right kidney. Left kidney much enlarged, otherwise not abnormal. Heart pale.

In both lungs several small patches of pneumonia. The muscles, throughout the body especially in the extremities, the trunk and the face (orbicularis), pale in color and moist; many small hemorrhages in sheaths of the muscles; rupture of left rectus abdominis, with hemorrhage.

Under the microscope muscles showed waxy and granular degeneration; fibres broken; small cell infiltration in the interstitial tissue, in no place amounting to the formation of abscesses visible to the naked eye. Nuclei of the muscles increased markedly, showing a real

proliferation of muscular tissue, as well as a degeneration.

I heard no report of a bacteriological examination, but, reasoning by analogy with diseases which have been studied, we may say that bacteria were most probably associated with the inflammation.

Prof. von Recklinghausen told me that when he was an assistant of Virchow's, he had seen two similar cases, but I have been unable to find a report of them.

We have here some acute disease of a febrile nature, rapidly ending in death. At the autopsy a widespread myositis is found, otherwise no pathological lesions which can be considered as a primary cause of the severe symptoms existing during life.

Dr. Blodgett kindly called my attention to a similar case published lately in the *British Medical Transactions* (December 18th, 1886, p. 1215). Acute myositis, (Mr. Treves.)

After exposure to severe cold, the following symptoms were manifested: chill, malaise, fever, loss of power in arms, cramp-like pain. Similar pains in legs. Gradual recovery in six weeks. Mr. Treves divides myositis into: (1) Simple, due to injury. (2) Myositis from cold. (3) Infectious boil or osteo-myelitis. (4) Attending various infectious diseases. (5) Trichinae.

This is the only case I find in the recent medical journals, German or English. In the fourth volume of "Virchow's Archives," (1852), is an article by Virchow on myositis. Anatomically, he divides myositis into: (a) Interstitial; (b) Parenchymatous; (c) A combination of (a) and (b). Etiologically divided into: (a) Traumatic; (b) So-called muscular rheumatism; (c) Syphilitic; (d) Septic. Then goes on to say: (e) "One sees finally abscesses occur in muscles under conditions as yet not made out, under conditions spoken of by the Vienna school as 'spontaneous pyæmia.' General symptoms are chill, high fever, disturbance of heart, severe, widespread pains; death in few days. Such processes may be of spontaneous origin, more commonly due to other septic diseases, especially typhoid."

A similar allusion I find in Fürster. In Lobstein a case of death where the only lesion was a myositis (general?) and local patches of pneumonia.

In none of the more recent works on pathology do I find any mention of a myositis, widespread in area and independent of some preëxisting centre of infection.

## Reports of Societies.

### MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT. SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

APRIL 13, 1887. Meeting called to order, at 8 o'clock, by Dr. F. I. KNIGHT, Chairman.

First paper, read by Dr. HENRY JACKSON:

#### A CASE OF ACUTE, INFECTIOUS, UNIVERSAL MYOSITIS.<sup>1</sup>

After the reading of this paper, Dr. FITZ said the chief interest in this case, apart from its rarity, lies in its etiology. It is well known that the muscular

<sup>1</sup>See page 488 of the Journal.

system bears a similar relation to infective agencies to that presented by the spleen, kidneys, and liver. Granular degeneration of the heart is always sought for, and is usually found. In typhoid fever, the hyaline degeneration of muscle is to be expected, and occasionally results in the rupture of the abdominal rectus, with the production of a hæmatoma. Such granular and hyaline changes are usually independent of extensive interstitial changes, but, in the infection of wounds, accompany the abscesses and purulent infiltrations, which may extend a long distance from the point of infection. In a dissecting wound of the hand or finger, the intervening structure may present little or no change, while a suppurative myositis may be present in the corresponding shoulder or scapular region of the individual. In typhoid fever also, muscular abscesses, even multiple in various muscles — may occur in addition to the more common degenerative changes.

In the case reported, the multiplicity of the lesions in remote parts of the body suggests the transfer of a virus through the blood-current. The described appearances of the spleen and heart give evidence of a general infection, while the condition of the muscles indicates the presence of pyogenic bacteria, as well as of those agencies which produce parenchymatous changes.

Multiple, miliary lesions of distinctly bacterial origin are usually due to a bacterial endocarditis, the malignant or diphtheritic variety. The peripheral lesions which are then found are usually rather hæmorrhagic and necrotic than suppurative, and more often cutaneous and nephritic than muscular. The peripheral lesions may be found without actual destruction of the valve-curtains. Pathogenic bacteria may be transferred, in the course of the circulation, to such deep-seated parts as periosteum and bone-marrow without evidence of disease in the lining membrane of the circulatory apparatus. It does not, therefore, seem remarkable that such cases as the one reported by Dr. Jackson should occur, but that they do not oftener arise.

The case reported by Treves has already been referred to, and Hayem states definitely that there is a sort of subacute, suppurative myocarditis, circumscribed or diffuse, general, infectious, wholly analogous to the malignant forms of periostitis and osteomyelitis. In the discussion of Treves's case, it was made evident that cases of this sort might be hidden under the diagnosis of acute muscular rheumatism, as well as under that of spontaneous pyæmia.

It is evident that the muscular system, in the study of infection, may demand as careful consideration, both clinically and anatomically, as the bones and marrow, both of which have lately contributed such valuable information to the history of infection. The channels of invasion may be extremely narrow: a pimple or a hang-nail, a scratch or a prick, may serve to open the way for a malignant pustule or a phlegmonous inflammation. In Dr. Jackson's case, a diphtheria may have been the primitive disease, or the pharyngeal symptoms may have resulted from the action of the agent which produced the muscular changes. Certainly, the report of this case will call attention to what is, perhaps, less likely to be regarded as a new disease than as a peculiar manifestation of a familiar agent.

DR. BLODGETT asked Dr. Jackson how, or in what

way, the myositis, which is, in this case, thought to be due to an infection of the muscular system by a specific principle, differs from the form of myositis so frequently seen after exhaustive diseases, particularly typhoid fever. After this disease, we not infrequently observe limited areas of muscular tissue, especially in the domain of the abdominal rectus, presenting the appearance of a true myositis, which is followed by hyaline degeneration of the muscular structure, and by loss of substance in the part.

DR. JACKSON. I think the muscular lesion due to typhoid fever and that due to infective myositis are, pathologically, the same. The first process is usually confined to the muscles of the abdomen, whereas, in this case, the same pathological condition was widespread throughout the muscular system.

DR. SHATTUCK then reported

#### FOUR CASES OCCURRING IN HOSPITAL PRACTICE.<sup>2</sup>

DR. MINOT. Dr. Shattuck's case of Tetany corresponds closely with the description of that disease in a paper read by Dr. Lyman, of Chicago, at the annual meeting of the Association of American Physicians, in June last, and printed in the Transactions of the Association. Other cases were reported at the same time by Dr. Carpenter, of Pottsville, Penn. I should say that the disease is not extremely rare in children under four or five years of age. We see the thumbs bent towards the palm of the hand, the other fingers partially flexed, and the toes strongly flexed. There is usually some swelling of the hands and feet. These children are almost always feeble, insufficiently nourished, and often bottle-fed, perhaps undergoing the process of dentition. In one case, that of a child, three months old, under my care, which was artificially fed, immediate improvement took place when a wet-nurse was procured for the patient, who is now fifteen years old, and in good health. I have never seen a case in an adult which I recognized at the time, but possibly that of a physician who consulted me, and also Dr. J. J. Putnam, might come under this category. The movements were very striking, and corresponded to those in one of Dr. Lyman's cases, which were communicated to him by another physician.

With regard to the subject of hæmophilia, I think it remarkable that the now well-known spontaneous hæmorrhage of new-born children (umbilical hæmorrhage), which is to all intents and purposes the same disease, although fatal in eighty-four per cent. of the cases, yet in the few cases which recover does not recur, the hæmorrhagic tendency being, as it were, extinguished, as I have seen in several instances.

DR. PUTNAM. I will merely speak of the case mentioned by Dr. Minot. I have never seen any of these attacks, but it certainly did not suggest itself to me at that time as a case of tetany. The only well-marked case that I have seen occurred in an under-fed child of not more than a year old. In adults I have never seen it. I have seen a large number of nervous diseases at the hospital, probably five hundred a year for a number of years, and I have never seen a single case of this kind.

DR. WEBBER. I remember two cases of tetany; I was asked to see a patient several years ago, the muscles of the legs and trunks were affected, the arms less so. When the attack came on the patient suffered very severely from a strong muscular contraction

<sup>2</sup> See page 498 of the Journal.

which could not be overcome by manual force. Ether had been used to some extent for relief. The drug which gave the most relief was fluid extract of conium, after some doses had been taken at intervals of two hours, the attacks ceased; the man got well. He had had the affection for a number of days before I saw him. The other was a case in which the arms were chiefly affected, the trunk was not affected. The spasms had continued for several weeks, several attacks each day, but nothing I could do gave him any relief. I tried conium, electricity, etc. The attacks were quite painful. The man came to see me several times but obtaining no relief, became discouraged, and I saw no more of him. The attacks were very similar to those described by Dr. Shattuck.

DR. KNAPP. Tetany is so rare an affection that I may be justified in citing a case which resembles some of those spoken of to-night. The patient was a neurotic, poorly-nourished boy of fourteen, who had been at some charitable school, where the food and hygienic surroundings were not of the best, and where, according to his story, he was not very well treated. A week before he came to the City Hospital, he held his breath for some time in order to avoid a disagreeable smell, and after this he began to have cramps, numb spells, and "pins and needles" sensation in his hands and feet. The cramps affected the whole body, and the pain was so severe as to make him cry out. These attacks came on quite frequently. During the cramps he found it difficult to speak or move. They lasted from half a minute to a minute. He had occasional sick headaches and was rather costive. He was not strong, and was rather deficient mentally, and, as I said, was poorly-nourished, and rather emaciated. While in the out-patient room he had an attack which I was able to observe. He seemed nervous and agitated as it came on. He said that the attack began in his feet and went up, the muscles of the abdomen being most affected. He stood up, his limbs were rigid, his arms were by his side with the fingers much extended and somewhat adducted, his face was drawn with an expression of pain — whether from spasm or voluntarily from pain, I could not say, — he made no movement, except a slight general tremor, and he made no answer to my questions, because he could not move his lips and tongue, as he told me afterwards. He understood perfectly what was said during the spasm. Motion relieved the spasm. After recovery from the spasm I examined him, finding nothing abnormal in the chest. Pressure was made over the median nerve and brachial artery, and soon after a second spasm came on. Further pressure, after this, did not excite another spasm, so that I am disposed to regard this as merely a coincidence. I then examined him with electricity. The muscles and nerves of the arms responded to a very mild faradic current. With the galvanic current  $KaSZ = AuSZ$  with  $\frac{1}{2}$  Ma. in the various muscles of the arm. The median nerve responded to  $\frac{1}{2}$  Ma. The boy was sent into the hospital, but I am unable to give any further account of him, except that a diagnosis of pavor nocturnus was made, which was only a part of his trouble.

I am still unwilling to call this case tetany. The spasm involved the muscles of the trunk, which is rare except in the severest forms of tetany; the fingers were extended and adducted, instead of being flexed and adducted as in the hand when it is about to be introduced into the vagina; there was no undue

excitability of muscle or nerve to electricity, and the attacks were not provoked by pressure on the nerve or artery. Such a combination of symptoms, therefore, is not like the symptom-complex of tetany, as given in the books, yet the condition was certainly curious.

DR. WEEKS. I have met one family of bleeders, who did not seem to feel the law of transition laid down by the authorities. Some five or six years ago I was called to a little child about two years of age, who was teething, and had a slight abrasion of the gum from which a persistent hæmorrhage had been going on for some time. I applied styptics, and after a time the bleeding ceased and has never recurred. I learned that the elder boy, some ten or twelve years of age, was troubled in the same way when he was an infant, and had since outgrown the diathesis. The family were of German extraction on the mother's side, the father was an American I believe. The mother seemed quite an intelligent woman, and said that her father was a physician, and that the case of the elder boy troubled him somewhat; he said he knew of no cases of the kind in his family or his father's family. This same boy I was called to treat, some two years afterward. I went to Melrose where the family had moved, and got there perhaps an hour or more after being notified, as I was out when called, and when I got there he had died of epistaxis.

DR. BAKER. I would like to ask whether a tendency to umbilical hæmophilia was ever transferred to the offspring? Whether their children showed it?

DR. WEEKS. I have never seen a case of direct transmission. The case I mentioned was that of a young lady now married; I went to attend a relative of this patient, either a sister or cousin of hers; that is, the sister of the first one who died, was a victim to this disease. My impression was that she was married and left a son about eight or ten years old. He has never had any disposition to bleed. These cases are almost always considered hereditary. The remarkable point was that when the patient recovered, she recovered completely and permanently, and never had another attack.

DR. BLODGETT. I have had an opportunity of learning the history of one case similar to that reported by Dr. Shattuck, of a certain family concerning the history of which I have considerable knowledge. This patient, a male, was one of several children of the same father and same mother. He is the only one who showed a disposition to bleed. On several occasions he bled alarmingly from the nose, the surface was blanched, he became unconscious, and was evidently in the very last extremity. He has not had other forms of hæmorrhage, and the nose-bleed was the only accident he dreaded and from which he expected one day to lose his life. He is now fifty or sixty years old. Certainly the great part of his life has been passed in imminent peril of death from loss of blood, and he has been at death's door from this cause a number of times.

I do not know that I am warranted in calling this a case of hæmophilia, though it was very severe in its character, nothing of the kind ever made me feel like classing this case as similar to the one reported by Dr. Shattuck. I have the genealogy of two or three families in which bleeders abound. I have a note of a brother of the patient having died from the extraction of a tooth. I think the young man may belong to the very rare category of hereditary bleeders.

DR. KNAPP. I should like to ask Dr. Webber if he tried Trousseau's method?

DR. WEBBER. I think one case occurred before I read Trousseau's account, as to the other case I do not remember.

The next paper was by DR. FOLSON.

#### CASES OF MULTIPLE NEURITIS.<sup>3</sup>

DR. WEBBER. Dr. Folsom has given an exceedingly interesting paper. The first case I think is remarkable for its recovery, that the patient should recover where so many nerves have been affected. If I understand correctly, the nerves supplying the glottis were not affected, but that the patient could swallow, and nutrition was kept up; the food did not get into the bronchi. In two patients under my care the disease was fatal from the food entering the bronchi so that the patient could not be properly nourished. I think the milder cases are more common where comparatively few of the nerves are affected, the disease seems to run its course and then there is a change for the better. In a few cases there is such a similarity to rheumatism, with swelling of the limbs affected, and even sweating, that the cases might be mistaken for rheumatism.

Dr. Jackson's account of the case of myositis remind one of some cases of multiple neuritis. I saw one patient six months after quite a severe attack affecting the legs, and had an opportunity of examining the tendon reflexes in the patient, who congratulated himself on his perfect recovery, and came to see me to say that he was perfectly well. I could not elicit any response at all. I suppose a good many cases in which the cause is obscure can be traced to exposure. I had within the last year or so a lady who had neuritis of one arm, all the nerves of the arm and shoulder seeming to be implicated. There was no history which could sufficiently explain the attack, and no special exposure. It is quite possible that such a patient standing on the street or riding in a horse-car with the wind blowing on that side of the body might have been exposed sufficiently to have a neuritis developed, the person being a little more susceptible from being run down or in a condition less capable than usual to stand such an exposure. Blisters seemed to do her more good than anything else. She expressed great relief after using them. She continued their use at her home. She would put a blister on the spot which was tender, with complete relief to the pain. In the more severe cases of idiopathic neuritis after the very first acute period seems to have passed, much benefit may often be obtained from blisters. I found also considerable help in relieving the pain, from a four or five per cent. solution of carbolic acid, keeping it on the part continuously. Occasionally the patient complains of heat, and a burning sensation, but it relieves the pain. I have found nothing that ever stopped the disease; patients seemed to get well themselves after the disease had run its course. I have not had much experience with alcoholic neuritis; I suppose that I doubtless saw and treated such cases before the subject was brought prominently to the profession, and have called them by some other name. I am suspicious that one or two cases of supposed locomotor ataxia may have been neuritis. I have seen one case which I am very sure was neuritis and not locomotor ataxia. I think that was a case in which alcohol played a part in its etiology. In one

case in which I think alcohol caused the disease, alcohol relieved the pain, and the attending physician advised the patient to take whiskey, and he took it and increased his danger and the gravity of the disease in that way. He came out of it remarkably well and comparatively recovered; but alcohol was not recognized at that time as a cause of such symptoms.

The mode of treatment that Dr. Folsom speaks of, massage and electricity, I think is very judicious after the acute stage, and when the tenderness has disappeared. I know of nothing else which restores the functions so readily, but after doing the best we can in some of these cases there is not a complete recovery, there is a remainder of disability of certain muscles, or contracted limbs, thus to some extent incapacitating the patients from moving about in ease and comfort.

I have seen a few cases where even after eight months there was still lack of function when all progress towards recovery had seemed to cease.

DR. PUTNAM. I have only to say that I have been very much interested in this remarkable disease, the prominent features of which have been so vividly presented by Dr. Folsom. In regard to the first case, I do not see sufficient clinical reason for considering it to be of infectious character. This disease is not epidemic with us as it is in the South. I do not see how it materially differs from the alcoholic cases. Some cases are very remarkable for the pain, and in some there is little acute pain, and the duration of the cases is also very different under different circumstances. The fact has not been sufficiently dwelt upon of late that central disease and acute neuritis sometimes go hand in hand.

DR. F. C. SHATTUCK mentioned the chief points of interest in an outbreak of beri-beri, a disease which, as the reader said, may be taken to represent the class of infectious multiple neuritis, one of the sufferers from which he had seen a few days since.<sup>4</sup> There are strong reasons for thinking this disease to be infectious, though we are still entirely ignorant as to what the infection is and what is its avenue into the system. The disease appears under different forms, but in a form which is certainly a common one, differing in some respect from non-alcoholic multiple neuritis, originating in these latitudes. In beri-beri paresthesia is pronounced and cutaneous oedema is marked—dropsy of the internal cavities is not rare—but severe pain and great tenderness along the course of the nerve-trunks are not prominent symptoms.

DR. BLODGETT stated that he had the notes of a strange disease he now thinks to have been a case of beri-beri. The patient was the captain of a vessel sailing from Calcutta. While in that port, he became very ill, and was treated by several physicians, who considered the case to be of syphilitic character. The symptoms were of grave nature, and were confined to the central and peripheral nervous structures. There was considerable disturbance of the sensorium, with pain and swelling of the limbs, which subsided only slowly, and never completely. The patient was never able to resume his duties on board ship, but became erratic and morose, wandering from one locality to another, and only recently after a duration of the disease for more than twelve years, he died in Colorado.

DR. FOLSON. Before primary multiple neuritis was described in the medical text-books, the first cases

<sup>3</sup> See page of 493 this number of the Journal.

<sup>4</sup> Journal, April 14, 1887.

which I saw reported were in German medical journals, and later in those of England and the south of Europe. One which I saw several years ago was in a gentleman not pressed by business, just returned from a long vacation, during which there was no exposure, at least to cold or wet. The first symptoms were a numbness in both legs with inability to lift his thighs high enough to step up on a platform. Afterwards there was great pain and sensitiveness to pressure or motion in the course of all the spinal nerves. The other symptoms were like those of infectious diseases, fever, thirst, loss of appetite, dry skin, coated tongue, headache, elevation of temperature, although of only about a week's duration, and a generally typhoidal appearance, like all the others which I have seen. The important points in treatment are full nutritious liquid diet, quinine, wine if needed, relief of pain and especially the use of massage and galvanism at the earliest time practicable not to increase the pain. In marked paralysis of the extensors of the feet, splints will be required. I have not found carbolic acid so useful for external application as opiate liniments. Although patients in favorable cases can walk and have a fair use of many of their muscles in from three to six months, two or three years, or even more may be required for the best attainable results.

DR. KNAPP. There were certain symptoms in two of the cases reported by Dr. Folsom which seem worthy of special notice, on account of their influence upon diagnosis. Most of the text-books on nervous diseases lay stress upon the existence of bed-sores and of disturbances of the bladder as evidence against multiple neuritis, and in favor of some disease of the cord. Dr. H. C. Wood, in his recent work on "Nervous Diseases and their Diagnosis," is the only author who states definitely that bed-sores may exist in neuritis, although Gowers implies that such a thing may happen. Dr. Folsom's cases show that both bed-sores and vesical disturbances may be present in this disease. In this connection it may be of interest to speak of a case of traumatic neuritis I saw at the City Hospital a year ago. A hod of mortar fell on a young man, cutting his head and striking his shoulder. He developed a paralysis of the whole arm, which recovered in part, leaving a typical form of Erb's shoulder-upper-arm paralysis. His deltoid, biceps, brachialis anticus, supinator, longus, and infra-spinatus were completely paralyzed. There was great atrophy and reaction of degeneration. There was loss of sensation for a time over the lower part of the upper arm. The pain at first was so great that he would often support his arm on his elbow, for relief, but I could get no statement that he kept it constantly in this position, or that great pressure was exerted on the elbow. However that may have been, a typical bed-sore formed over the elbow, lasting several weeks.

tions of the pancreas and stomach. The case, he said, he brought to the notice of the Association on account of the infrequency of the affection, and the obscurity, as regards its diagnosis. Perhaps, however, such cases were not as infrequent as was generally supposed, since many patients died with symptoms similar to those met with in the present instance which were attributed to some other disease; whereas, if autopsies had been made, the primary cause of death might have been found in the pancreas.

In the case in question there were absent three important and common symptoms generally regarded as diagnostic of cancer of the pancreas, namely: jaundice, oedema and fat in the alvine discharges. According to Dr. Norman Moore,<sup>2</sup> jaundice was always found when the pancreas was the primary seat of a new growth. In ten cases coming under his observation in which post-mortem examinations were made, jaundice was present in all. Sir Charles Murchison also referred to jaundice as a common symptom of the disease; but Dr. Louis Starr had shown that it was of clinical importance to note that the ductus coledochus does not always pass through the head of the pancreas but sometimes merely passes over it; in which case, any enlargement of the pancreas could simply push it aside, without giving rise to jaundice. According to Wyss, this happened fifteen out of twenty-two times.

Oedema occurred, according to the majority of authorities, in more than half the cases of cancer of the pancreas recorded; while fat in the alvine discharges was said to be found in nearly all the cases. The same condition, however, might occur, according to Reynolds, when the duodenum, and not the pancreas, was diseased. Dr. Taylor said that he had been unable to find any authority who gave even one pathognomonic sign, and therefore he thought that Da Costa's manner of diagnosing these cases was the most feasible, namely, by exclusion. As to the invasion of the stomach in the present instance, according to Pepper, this disease rarely extended to the stomach, but rather affected the neighboring lymphatic glands, the duodenum, and the liver.

In regard to the possibility of prolonging by operative procedure the life of a patient suffering from cancer of the pancreas, provided the diagnosis could be made out sufficiently early, he thought that the two cases reported by Billroth were of much interest, where he had made a partial resection of the organ; removing the tail in one and a portion of the head in the other, but, of course, not injuring the duct. Both patients recovered from the immediate effects of the operation, but how long they lived, or whether the disease returned, he did not state. Dr. Taylor thought that when he first saw his case but a very small portion of the head was involved, and that if the diagnosis could then have been established, it would have been an excellent opportunity to perform an operation similar to that of Billroth.

#### AMPUTATION OF THE PENIS FOR EPITHELIOMA.

DR. J. R. MACGREGOR presented a portion of a penis which he had amputated for epithelioma of the glans and prepuce. This variety of cancer, he said, was very interesting, not only as regards the result to the patient, but also from its special pathological features. In this case there was a great deal of thickening, and the connective tissue of the part was greatly

#### NEW YORK COUNTY MEDICAL ASSOCIATION.<sup>1</sup>

##### CANCER OF THE PANCREAS.

DR. THOMAS C. TAYLOR read the report of a case of carcinoma of the pancreas, with infiltration of the omentum and walls of the stomach, along the greater curvature, occurring in a female thirty years of age. In connection with it he presented the diseased por-

<sup>1</sup> Concluded from page 485.

<sup>2</sup> St. Bartholomew's Hospital Reports.

increased. At the time of the operation, which was performed six weeks before, much care had been taken to prevent any subsequent constriction of the urethra at the end of the stump, and thus far the result had been altogether satisfactory. The chances were also fair, he thought, that there would not be a reproduction of the growth.

DR. GOSLEY said that it was an interesting fact that, in epitheliomatous growths of the glans or prepuce, there was always antecedent balanitis or balanoprophitis, and the greater proportion of cases occurred in individuals who were the subjects of chronic balanitis. This condition was, for the most part, due to lack of cleanliness on the part of the patient, allowing of the accumulation of smegma behind the glans, and at first there was simply an alteration in the normal epithelium. Afterwards, this went on to be developed into this peculiar form of carcinoma, and the proliferation was rapid enough not only to involve the mucous membrane, but to extend to the cavernous bodies of the penis.

So far as his experience went to show, the amputation operation usually resorted to in this class of cases was insufficient, and was apt to be followed by a recurrence of the disease, more or less rapid, this new development always occurring at the end of the stump. Atresia of the extremity of the urethra was apt to be a very unpleasant consequence of the amputation of the penis, and he related a case which first came under his observation when he was a hospital interne, in which, although there was no return of the cancerous disease whatever, the patient died within two years from pyelo-nephritis, resulting from atresia of the urethra produced in this way. About 1860, having occasion to amputate a penis for epithelioma, Dr. Gosley said he first used the *cérasseur* to break up the cavernous bodies. Then, leaving the urethra fully three-quarters of an inch longer than the stump, he attached it to the free extremities of the cavernous bodies. By this and other devices, therefore, it was not difficult to avoid atresia of the end of the urethra.

In consequence of the frequency with which the epitheliomatous growth recurred, however, he finally made up his mind that, in the next case he met with, he would excise the whole penis; and, accordingly, in April, 1878, he resorted to this procedure in a patient fifty years of age. He dissected out the entire penis, without opening the cavernous bodies, removing the crura and all. In this instance, about one-half of the cavernous bodies had been involved in the cancerous process. The patient was discharged, cured, on the 11th of June following, but he was unable to say what was the subsequent history of the case. Having exhibited this penis, preserved in alcohol, Dr. Gosley went on to say that it seemed to him that a radical operation of this kind gave the patient the best chance of avoiding a recurrence of the disease, for, if the slightest epitheliomatous deposit were allowed to remain, the growth was sure to go on developing again. He believed, therefore, that in the majority of cases it was not only justifiable, but the most proper measure to adopt. It seemed like a formidable operation, but, in reality, it was not, and in the case in which he performed it the patient made a rapid recovery after it.

DR. JOSEPH D. BRYANT said that he had had some experience with amputation of the penis, and he very distinctly recalled three cases of it in particular. In two of them the operation was undertaken for cancer-

ous disease, involving the glans and anterior portion of the penis, and in the third for general carcinoma, involving not only the penis, but the whole system. The latter, as a case of remarkable interest, he related in detail. At the autopsy, it was found that there was scarcely an organ in the body which had not been invaded by the cancerous disease. The kidneys were probably the starting-point of its development, and even the spinal cord was among the structures involved. One of the other patients referred to was a young man of twenty-five, who attributed the origin of trouble to a woman with whom he had had intercourse, whom he believed to be affected with the same disease.

In these cases, he had performed the amputation just in front of the scrotum, cutting the spongy body three-quarters of an inch longer than the corpora cavernosa, and attaching the integument to its extremity. He said that he was fully of the belief that the entire removal of the organ was the only ultimately safe procedure. He could understand, however, that if the growth were very slight, it might be allowable to consult the patient's wishes on the subject, and, if he objected, make the amputation pre-scrotal.

## AMERICAN SURGICAL ASSOCIATION.<sup>1</sup>

ANNUAL SESSION OF 1887.

THURSDAY, MORNING SESSION.

THE Committee of Conference with reference to the Congress of American Physicians and Surgeons reported that they had attended the meeting of conference held in Washington, September 24, 1886. At this meeting the following resolutions were adopted:

*Resolved.* (1) That it is desirable that the following special societies, the American Surgical Association, the American Ophthalmological Association, the American Otological Association, the American Neurological Association, the American Laryngological Association, the American Gynecological Association, the American Dermatological Association, the American Climatological Association, with the Association of American Physicians, shall arrange for a conjoint meeting in the city of Washington, September, 1888, and subsequently at intervals of three years at the same time and place.

(2) That this arrangement shall not interfere in any way with the autonomy of each special Society, and that each Society shall retain the right to withdraw at any time from this conjoint scheme.

(3) That the special feature of the meeting shall be the conjoint assemblage of the special societies on two evenings during the session; on one of which there shall be an address delivered by the president of the conjoint meeting, and on the other there shall be communications by a referee, and co-referee on some subject of general professional interest.

(4) That each special society approving this report is invited to appoint one representative (with an alternate), and that the representatives so appointed shall constitute an executive committee to serve for one year, with power to select such officers for the first conjoint meeting as may be deemed necessary; to propose a programme for said meeting; to make all other

<sup>1</sup> Continued from page 483.

arrangements and to prepare and submit a plan of organization for future meetings.

(5) That all expenses connected with the conjoint sessions shall be apportioned equally by the executive committee among the special societies participating.

Owing to the views entertained by the Committees of the Ophthalmological and Dermatological Associations with regard to the interval of times of meeting they abstained from voting upon the first resolution.

The report was adopted, and Dr. C. H. Masten of Mobile, (with Dr. J. Ford Thompson, Washington, as alternate) was appointed as the representative of the Association.

The following was announced as the Nominating Committee: Drs. J. Collins Warren, J. Brinton, T. F. Poewitt, N. P. Dandridge and D. W. Yandell.

The Treasurer, Dr. P. S. Conner, reported a balance of \$738.46 in the treasury.

#### CYSTOTOMY AND LITHOLAPAXY.

The discussion of papers read on Wednesday was then taken up.

Dr. W. T. BRIGGS, of Nashville. Dr. Dennis, in his paper, held that the time would come when suprapubic lithotomy and litholapaxy would practically be the only operations performed for the removal of stone. My idea is that no special operation is applicable to all cases. The surgeon should have all operations at his command and should select the one adapted to the particular case. In certain cases such as large stones or deformities of pelvis and lower extremities, suprapubic lithotomy is undoubtedly the best operation. There is, however, no reason why in ordinary cases of medium stones, the perineal operation should not be adopted. The operation which I regard as the best is one through the median line. The external wound permits dilatation to any extent. The neck of the bladder is usually resistant, but by making a lateral incision of three lines on each side of the prostate gland, with gradual dilatation, the opening can be enlarged to an extent sufficient to permit the removal of any stone that should be removed through the perineum. I exhibit a number of stones (varying from one inch to one-and-a-half inches in diameter) which were removed in this way, with recovery of the patient. There is no reason why fragmentization of a large stone should not be combined with the medio-lateral operation. The operation is easier than the lateral operation. Incision in the manner mentioned with the removal of all stones at once, will, I think, have a less mortality than litholapaxy.

Taking all kinds of cases at all ages, my first seventy-four cases were operated on by this method without a death. Then I had two deaths; in one a pelvic abscess complicated the case, and in the other there was scrofulosis. Forty-six cases were then operated on with one death. This case died three months after operation of general tuberculosis, with wound ununited. It is probable that in properly prepared patients without organic disease, the mortality will be nothing. In the last two years, I have operated on six old men, with an average age of sixty-six years, all recovering.

Dr. D. HAYES AGNEW, of Philadelphia. As Dr. Briggs has said, we cannot commit ourselves positively to any one operation. The median operation is undoubtedly the safest operation through the perineum. The only damage likely to be done is in extraction, but

this can be avoided by nicking the neck of the bladder, which admits distension to almost any extent. Where the stone is large and yet is one which should come through the perineum, an incision may be made on each side. Drainage is more readily effected by the perineal operation. With antiseptic precautions the success of this operation will be even greater than at present. In cases of large stone the high operation is the best. When one operates year after year through the perineum as Dr. Briggs and others of us have done, with almost universally successful results, he is indisposed to give up what he believes to be a well-trying method for one which is a comparative novelty.

Dr. J. R. WEST, of Richmond, Ind. After seeing Dr. Briggs perform the medio-bilateral operation, I have adopted this method in eight cases, all of which recovered. With one exception all the patients have been old. One case was twenty years of age, and a mulberry calculi weighing 520 grains were removed. The next youngest case was fifty-nine years old, eight stones being removed. In another case, seventy-two years old, twenty-two stones were removed. From the accounts of the supra-pubic operation given yesterday, I infer that the operation is more difficult of performance than the one described by Dr. Briggs.

Dr. H. H. MURD, of St. Louis. My first operations were performed by the perineal method with good results. I then began the use of litholapaxy, which in the majority of cases takes the place of the perineal operation. The supra-pubic operation is of service for the removal of certain large stones and for exploratory purposes. In considering this operation it must be borne in mind that the existence of contracted bladder with adhesions will render the supra-pubic operation difficult or impossible.

Dr. J. COLLINS WARREN, of Boston. During the past year I have seen two cases of the supra-pubic operation, both in the practice of others. One was for stone and the other for tumor. There seemed to be no difficulty in the operation. Both cases recovered without a bad symptom. I have investigated the subject of cystotomy in the female, and reached the conclusion that there was no danger of vesico-vaginal fistula.

Dr. THEODORE R. VARICK, of Jersey City. Two years ago I operated on a boy, fourteen years of age, who had had symptoms of stone for seven years. I started with the left lateral operation, but on account of the size of the stone had to carry the incision to the right side. The stone removed weighed seven ounces and two scruples. There was no perceptible laceration, and the boy recovered completely. In cases where there is hemorrhage, I have used with advantage, the application of water just under the boiling point, saturating a sponge and placing it for a short time on the bleeding surface.

Dr. DAVID Y. YANDELL, of Louisville. I have performed ninety-two operations by the perineum, eight by lithotomy, and six by litholapaxy. I have seen two supra-pubic operations, but it does not seem to me that this operation is an easier or better one than those which I have mentioned. There were seven deaths from the lithotomies. In none of the cases was there any return of the stone. In the eight lithotrities there was a return of the stone in two cases. In the six Bigelow operations there was a return in two cases. The question in my mind is still *sub judice*, and until more evidence has been pre-

sented, I shall adhere to the opinion that the best operation is that made through the perineum.

Dr. JOHN B. ROBERTS, of Philadelphia. I cannot change the opinion which I expressed three years ago, that the high operation is certain to be a very important one. If we wish to make a free exploration of the bladder, the high operation is better than the one through the perineum. In cases of stone operated on by a surgeon without special experience in this direction, I think that the supra-pubic operation is the safer. With reference to Dr. Packard's suggestion to treat retention of urine from stricture by supra-pubic cystotomy, I should consider this too serious a step to take in the first place. My own view is that persistent efforts should be made to introduce a filiform bougie which will drain off the urine. Simple aspiration above the pubes will give a chance for the passage of an instrument through the urethra in two or three days.

Dr. J. E. MICHAEL, of Baltimore. With reference to supra-pubic opening of the bladder for retention due to stricture or prostatic disease, I have had considerable experience in this direction, and have never found such an operation necessary. Supra-pubic aspiration seems to be all that is necessary, and under proper precautions is safe. Then in prostatic cases the use of a soft catheter will accomplish all that can be done without some radical operation is attempted. In cases of stricture this must be treated. As to the advisability of the supra-pubic operation for exploration for some cases of prostatic enlargement and for exceptional cases of foreign bodies, there can be no question.

#### A STUDY OF THE PROCESS OF REPAIR AFTER RESECTION OF THE INTESTINES AND SOME OF THE COMPLICATIONS WHICH OCCUR.

by J. COLLINS WARREN, M.D., of Boston.

The speaker first referred to the anatomy of the wall of the intestines, calling particular attention to the thin submucous fibrous coat, which was the strongest of the various coats of the intestine. The peritoneal and muscular layers as well as the mucous layer are easily rubbed away, but this fibrous coat is exceedingly resistant. In introducing the sutures in cases of wound of the bowel, it is desirable that a few fibres of this fibrous coat be included, but care must be taken not to perforate the mucous membrane. The fact that this has been reached is readily told by the resistance offered to the needle. A number of experiments made upon dogs were then described. The operation consisted in removing a portion of the intestine and a V-shaped portion of mesentery and then bringing the parts together. The Lembert suture was the one used. After the operation the bowel was replaced in as near its normal position as was possible. The dogs were killed at varying times after operation from three to eight days. In these cases the intestines were found matted together around the seat of operation, but a current of water flowed freely through the gut. In one case the abdomen was opened a few days after operation, and this matting together of the various coils of intestine found. The intestine was replaced and the wound again closed. Six months later most of the adhesions were found to have disappeared.

#### SHOULD LAPAROTOMY BE DONE FOR PENETRATING GUN-SHOT WOUNDS OF THE ABDOMEN, INVOLVING THE VISCERA.

by CHARLES B. NANCREFE, M.D., of Philadelphia.

The chief object in presenting this subject to the consideration of the Association, was a medico-legal one. A few years ago in a famous murder trial, the counsel urged the acquittal of the accused on the ground that the fatal result had been induced by the surgeon probing a penetrating gun-shot wound of the abdomen, and many authorities in support of this position were cited. At present the tendency is toward more active interference in these cases. The author asked that after a consideration of the subject the Association, the highest surgical tribunal of the country, express an authoritative opinion upon this question. The questions which must be decided are: what are the tendencies of the injury, are they towards recovery or death? When death takes place, what are its causes? When recovery ensues, what conservative processes occur? How likely are these conservative processes to take place and what favors or prevents them? How reliable are unaided natural methods compared with those which art affords, and should they be imitated or avoided by the surgeon? What are the dangers inherent to the operation of laparotomy and what advantages does it afford.

Reference was made to the experiments of Wegner and Grawitz, showing that the healthy peritoneum can dispose of air, serum, bile and healthy urine. When however, air and putrescible fluids in greater amount than could be disposed of in a short time, were introduced, decomposition occurred and septicæmia resulted. A notable exception was that living, defibrinated blood never decomposed under these circumstances. This seems to prove the truth of the suggestion of the author that the presence of fibrin-ferment and probably its absorption, is one of the dangers of peritoneal traumatism. The ordinary micro-organisms produce no evil effects, provided the quantity of putrescible matter does not exceed that which may be disposed of in a short time. In small quantities, the pathogenic micro-organisms produce no harm. Suppurative peritonitis is produced by these micro-organisms when stagnant fluids are present, capable of nourishing the bacteria, when the surface of the peritoneum has been destroyed by caustic fluids, and when there is a wound of the peritoneum.

The practical application of these experiments teaches that all blood and serum should be removed and free drainage provided; every wounded surface must be coaptated; if a tube is used, the opening must be carefully guarded; the depression of the circulation present during shock, must be removed, and the vascularity of the peritoneum must be kept as near the normal as possible.

When visceral wounds do undoubtedly exist, the tendency of these cases is invariably towards death. Hemorrhage in itself is rarely fatal, but a very small collection of blood may be followed by fatal consequences either through the induction of sapræmia or by furnishing pabulum for the development of organisms productive of suppurative peritonitis. In nearly every case death is due to septic peritonitis, caused by extravasated matters. Of those attacked with peritonitis, ninety per cent. die within twenty-four hours. When recovery ensues, the effused matter is absorbed, and a limited adhesive peritonitis glues the injured organ to the abdominal walls or to a neighboring viscus. This process is successful in about eight per cent. of the cases.

The conservative processes are favored by absent

or slight flatulent fecal, urinary or biliary extravasation, by the absence or slight amount of effused blood or serum, by the favorable relation of the wound with reference to neighboring viscera or the abdominal wall, above all by the aseptic condition of the peritoneum, the wounds and their immediate surroundings, and by complete arrest of the intestinal movements. It is apparent from what has been said that nature's methods are not to be relied on.

What are the dangers of laparotomy? Shock, and the risk of rendering a peritonitis septic and diffused, which might have remained local and simple, are the dangers of the operation, but as we have the power of rendering the inflammation resulting from the manipulations innocuous, shock is practically the only result to be dreaded.

If these facts, and the deductions from them be true, all ball wounds of the abdomen, involving the stomach, intestines, bile or urinary bladder, should be treated by suture, or by resection and suture; injured omentum should always be excised, and the serous surfaces carefully sutured. Wounds of the liver and pancreas are to be treated in the manner to be described. A wounded spleen or kidney is to be removed provided certain contra-indications do not exist. Even penetrating wounds of the abdomen without involvement of the viscera are better treated by exploratory section, than by the expectant method. In many instances unsuspected injuries of the bloodvessels and viscera will be found and appropriately treated. The speaker laid but little stress upon most of the symptoms said to be diagnostic of wounds of the viscera, and held that the diagnosis should be made by the eye alone. The track of the ball should be enlarged under aseptic precautions until it has been determined whether or not the peritoneum has been opened. Then median section should be performed to ascertain the existence of and repair any damage that may have been done. The above remarks can only apply to wounds of the anterior and lateral walls of the abdomen. When the posterior wall is involved it is unavailing to ascertain the fact of peritoneal penetration by direct exploration. In these cases a correct opinion is almost always difficult and often impossible without laparotomy.

The rational signs of peritoneal or visceral lesion were briefly mentioned. The escape of bile, feces, urine, or the contents of the stomach, at once determines the question of visceral penetration. These signs are, however, rare, even when visceral lesion is present. Repeated vomiting of considerable quantities of blood almost certainly points to peritoneal or visceral penetration. This symptom is unlikely to be present even when there are numerous wounds, unless one involves the stomach or upper portion of the small intestine. The passage of blood in quantity by the bowel, is strong presumptive evidence, but it rarely occurs early enough to be of practical diagnostic value for operative purposes. The presence of fluid within the abdomen, within an hour or two after the injury, is a positive indication of peritoneal penetration and probable visceral injury, for only intra-peritoneal hemorrhage could produce such rapid accumulation of fluid. The rapid accumulation of intestinal gas in the general peritoneal cavity is a sure sign of wound of the peritoneum and of the gut. To be of much value it must appear within a short time after the injury. Finally, an amount of hemorrhage which

cannot be accounted for after a careful examination of the parietal wounds, indicates penetration and vascular or visceral lesion.

Profound shock, if not due to hemorrhage, is a contra-indication to operation. The surroundings should not contra-indicate operation in a proper case, provided the operator be expert in abdominal surgery. Most cases will do better if left to nature than they will if operated on by a bungling surgeon. If well advanced peritonitis exists, laparotomy is contra-indicated. Where there is no visceral complication, operation under these circumstances may sometimes be justifiable. Laparotomy, if done at all, should be done at the earliest possible moment that the condition will admit of it. Shock is the only thing that should delay the operation, and this should not do so if the condition is produced by hemorrhage.

In operating, strict antiseptic precautions should be carried out. The incision should always be median, extending from a short distance above the umbilicus to two inches above the pubes. Unless there be free hemorrhage, the small intestines should be carefully gone over, keeping them constantly enveloped in towels wrung out of hot water. Afterwards, the stomach, spleen, kidneys, bladder, etc., must be carefully examined. The source of a severe hemorrhage must at once be sought after. Wounds of the bowel should be secured with the Lambert suture, and dusted with a little iodoform. Wounds of the liver, if occupying its free border, should be coaptated, if possible, with dry, aseptic catgut, which will soon swell and fill the track made by the needle. If this cannot be done, the hemorrhage possibly may be arrested by the thermo-cautery, or, if the bleeding is free, the wound should be plugged with an iodoform-gauze tampon. If, at the close of the operation, the bleeding is almost completely checked, the cautery may be used as a further protection, and the tampon removed. If, however, the bleeding is still free, the tampon should be replaced and allowed to remain permanently. Wounds of the pancreas, spleen, and kidneys are to be treated in a similar manner. If these measures fail, the spleen or kidney is to be removed. Wounds of the bladder had better be united with dry catgut. Contused portions of the bowel should be excised; wounded or contused omentum or mesentery should also be removed. In removing a portion of the bowel, the cuts should correspond to the distribution of a large mesenteric branch. Should the pulse fail during the operation, flushing the abdominal cavity with hot water is often of service. The peritoneal toilet is most quickly and effectively made by irrigation with warm, sterilized water, and subsequent removal with sponges. Wounds of the peritoneum should be united. In closing the abdominal cavity, the peritoneum should be sutured with fine silk or catgut. The muscular aponeurotic and cutaneous structures should then be united with strong silk. The wound should be dusted with iodoform, and the dressing completed by the application of a pad of absorbent cotton and a flannel bandage.

Alimentation should be carried on by the rectum for forty-eight hours, when possible. Where peritonitis comes on after the operation, the treatment will depend upon whether it has developed rapidly or gradually. In the former case there is often evidence of shock from vaso-motor paresis, and in these cases, small doses of morphia, with atropia, will be of service, while large doses of opium may prove fatal. This

should be continued until pain is relieved, and the patient falls into a quiet sleep, from which he is readily aroused.

In the later stages of peritonitis, one or more hypodermics of atropia will, at times, save otherwise hopeless cases. For the control of the vascular processes involved in peritonitis, we have two powerful measures in the ice-coil to the abdomen, and in the use of leeches, if applied early, and the patient has not lost much blood. If the temperature continues to rise despite treatment, it is probable that ptomaines are being absorbed, producing supramia. In such cases, irrigation, with safe antiseptic fluids, is indicated.

In concluding, the speaker stated that everything advanced was to be viewed as more or less provisional, since sufficient experience in the operative treatment of these cases has not been accumulated to warrant positive statements.

#### THURSDAY. — AFTERNOON SESSION.

##### PISTOL-SHOT WOUND OF THE ABDOMEN TREATED BY LAPAROTOMY AND SUTURING THE INTESTINES,

by R. A. KINLOCH, M.D., of Charleston, S. C.

J. B., colored, aged twenty-seven, was admitted into the City Hospital, January 21st, at 7.30 p. m. He had been shot two hours before, in the abdomen, with a pistol-ball (38-calibre). The ball entered one-and-one-half inches to the left of the umbilicus. There was slight shock. The patient seemed to be comfortable, with the exception of a slight pain on the inside of the left thigh, which was intensified by movement. Pulse 88, respiration 24, temperature 99°. At 10 p. m., half-a-grain of morphia was given hypodermically, and shortly afterwards, anaesthesia was induced by the A. C. E. mixture. Penetration of the peritoneum was first determined, and the abdomen was then opened by median incision. A weak carbolic spray was used. The intestines were examined, piece by piece, and wrapped in towels wrung out of a one to ten thousand bichloride-of-mercury solution. The jejunum presented four wounds: two of entrance and two of exit. The ileum had two wounds. The mesentery was perforated in two places, and was also badly torn. There was free bleeding from a mesenteric branch, which was controlled by pressure-forceps, and subsequently, by ligature of silk. All the wounds were closed with the Lembert suture, using a fine, round needle and antiseptic silk. The wounds of the mesentery were brought together as far as was possible, but there was an infiltration of blood which could not be removed. The abdominal cavity was washed out with a weak solution of hydrarg. bichloride. The abdominal wound was closed with silver sutures, and a large rubber drainage-tube introduced. Antiseptic precautions were observed throughout the operation. The next morning vomiting occurred, and an examination of the wound showed that a suture had given way, and a knuckle of intestine protruded. This was returned, and the opening closed. At 5 p. m., the temperature was 102°. Vomiting again occurred, and shortly after midnight the patient expired suddenly.

*Post-mortem.* No adhesion of the parietal peritoneum had occurred. Half-a-pint of dark, sero-sanguinolent fluid was found in the cavity. All the intestinal sutures had held, and there was no fecal extravasation. A circumscribed abscess was discovered in the meso-colon, out of the line of the bullet. The ball

was found behind the body of the fourth lumbar, on the left side.

This was the third case in which the author had performed laparotomy for bullet-wounds of the abdomen, without visceral protrusion. The first operation was performed May 27, 1863, and the patient recovered. This was the first time that laparotomy was done for gun-shot wound without protrusion. In two other cases of such injury, the patients recovered without operation.

##### PISTOL-SHOT WOUND OF THE ABDOMEN, INVOLVING THE LIVER, STOMACH, SUPERIOR MESENTERIC VEIN, INTESTINE, AND KIDNEY. LAPAROTOMY: NEPHRECTOMY: DEATH ON THE FIFTEENTH DAY: AUTOPSY,

by W. W. KEAN, M.D., of Philadelphia.

Miss B., in Vineland, N. J., a plump and healthy, well-developed girl, of nearly eighteen, shot herself with a pistol, calibre No. 32, at 6.30 a. m., April 1, 1887. Dr. O. H. Adams, who arrived in a few moments, found that the ball had entered over the liver, and, after a careful search, found it lying under the skin of the left flank.

I saw her at 2 p. m. She told me that the wound was self-inflicted; hence the pistol had been almost in contact with the body, and the ball had probably passed in a straight line. The wound of entrance was over the ninth rib, which was fractured, four-and-a-half inches above the level of the navel, and three-and-three-quarter inches to the right of the median line. Skin not burned. The ball was located eight inches to the left of the median line, one-and-a-half inches above the level of the navel. There was moderate tenderness over the entire belly; hepatic dulness not changed; stomach resonant from fifth interspace; no cough, no râles, vocal fremitus normal. Renal dulness began at tenth rib, on left side, and was the same on the two sides. There was severe pain in the left shoulder. She had vomited a drachm-and-a-half of clear, bright blood, she told me, immediately after the accident. About a pint of urine, the first since the accident, was drawn by the catheter. It was not bloody. Pulse 104, respiration 30; no material rise of temperature. As, after consultation with Drs. Adams and Bidwell, it was deemed almost certain that the belly was invaded by the ball, exploratory laparotomy was advised, consented to, and begun at 3 p. m., and lasted nearly three hours, with every antiseptic precaution. The ball was easily removed, just under the skin. Neither wound could be traced positively into the belly. On opening the belly, neither blood nor serum escaped, nor was any extravasated food or faeces noticed. There was no peritonitis. Two fingers were passed in, and an effort made to discover the wound of entrance or of exit, without any being revealed by touch. The wound was then enlarged, and the stomach drawn out. A small, round wound near the pylorus was found, and was closed by four sutures (Lembert) of the finest iron-dyed silk, a round, ordinary sewing needle being used. This wound was practically closed by the poulticing mucous membrane. As the ball had entered the stomach, search was made for the necessary wound of exit. None was to be found, but the manipulation showed that a small amount of bloody serum existed in the belly, and a large area of extravasation was seen in the mesentery. But little blood had escaped into the peritoneal cavity. The mesentery was carefully torn through, and a small artery tied. The chief bleeding came from a hole

nearly one-eighth inch in diameter, in a large vein, so large and lax that at first I thought it the vena cava, but its position, just below the head of the pancreas, convinced me that it was a large, superior, mesenteric vein just before it forms the portal vein. After much difficulty, I seized it with hæmostatic forceps, and placed a lateral ligature of chromicized catgut on it.

The anterior border of the liver had been scalloped by the ball, but, as there was no bleeding, it was left alone. In addition, a large wound in a coil of small intestine in the left flank had been found; ten Lembert sutures were used in closing it.

Returning now to the stomach, a very careful search was again made for the wound of exit. It was found, obscured by a slight coating of blood. This was closed by three black-silk Lembert sutures. A systematic investigation of the entire bowel, from the stomach to the sigmoid flexure, showed no other wounds. The left kidney was badly lacerated, and was immediately removed by peeling it out of its capsule, and tying the pedicle with a stout silk ligature. A rubber drainage-tube was inserted through the wound of exit into the abdominal cavity.

The wound of entrance was cleansed and closed by three stitches, and the wound of exit by two. Sublimate gauze, rubber dam, and a wide flannel bandage completed the dressing.

During the day following the operation suppression of urine was threatened, only  $\frac{1}{2}$ ijss being secreted. This was quite albuminous. The next day, however, the amount rose to  $\frac{1}{2}$ xxiv, and on the third day, to  $\frac{1}{2}$ xv, and the albumen gradually disappeared. For the first three days nothing was given her, except a little cracked ice, ice-water, and a little whiskey and champagne. On the fourth day, peptonized milk, in frequent, but small quantities, was allowed, with rectal enemas of the same, and later, other liquid foods. Menstruation appeared regularly, when due, on April 3d, and saw its usual course of four days.

On the 8th she had a chill, lasting twelve minutes, and the temperature rose to  $104^{\circ}$ ; but as the most careful examination revealed no spot of special tenderness, no dullness, no fluctuation, and she was almost, it seemed, in articulo mortis, it was not deemed prudent to reopen the belly.

The next day, the 10th, she improved somewhat. On the 13th she had another chill, with a temperature of  $105.4^{\circ}$ . Had vomited several times, and also had some involuntary evacuations; but as her condition was fair, pulse 136, temperature  $101.4^{\circ}$ , the belly was reopened and explored. The intestines were bright and glistening, and no peritonitis existed.

Surgical bimanual examination revealed no pus or special tenderness at the site of the removed kidney, or, so far as it could be located, at the intestinal wound. No shock followed. The next (14th), she had two bloody motions, and gradually failed, dying on the fifteenth day.

The autopsy, by Dr. H. C. Smith, revealed general peritonitis, except in the pelvis, but no free pus was found anywhere. Only one wound was found in the stomach, near the pylorus, and this was healed, the four stitches being seen in place. The blood in the mesentery was disintegrating and suppurating, though no abscess existed, nor was there any free pus in the peritoneal cavity. The suppurating was chiefly marked along the mesenteric attachment of the intestine. On the other side of the mesentery, corresponding in posi-

tion to this wound, was a spot in the bowel-wall as large as a five-cent coin, which was gangrenous, and in its centre were two perforations of the bowel. No wound was found, except that discovered at the operation. No trouble was found at the site of the removed kidney. Although it was nearly ten hours from the accident to the time when the intestine and stomach were sutured, no intestinal or gastric juice or fluid escaped, though the intestinal wound was so large, and vomiting occurred three times.

The kidney, I believe, has never before been removed at a laparotomy for gun-shot wound, but it was clearly the right thing to do. The day following the operation, the remaining kidney worked badly, only three-and-a-half ounces of albuminous urine being secreted. But the next two days dispelled all anxiety on this score, the urine rising to twenty-four and forty ounces, respectively, and the albumen soon disappeared. The early and marked compensatory enlargement of the right kidney is also of great interest and importance, though, of course, now well known to follow nephrectomy.

#### DISCUSSION.

DR. P. S. CONNER, of Cincinnati. If the temperature remains sub-normal, four, five or six hours, prostration and perforation may be considered almost certain. Diagnostical laparotomy is admirable in certain cases. In private practice we have to be largely governed by the opinions of the patients and their friends. Many of these cases necessarily involve legal investigation, and it is a very simple matter to show that death resulted not from the original injury but from the surgeon's knife. While I think that it is wise to lay down the general rule that penetrating wounds of the abdomen and still more perforating wounds of the viscera should be submitted to laparotomy, at the same time I think we are not justified in laying this down as a hard and fast rule.

DR. MOSES GUNN, of Chicago. When Dr. Sims proposed this operation a few years ago, the profession were not ready to accept it. I think that we are now all prepared to say that it is a proper measure to pursue, but the only question is how to make the diagnosis? We have, as has been said, no positive signs of visceral injury. I think that we are fully warranted in saying that we may resort to laparotomy for purposes of diagnosis when we are in doubt.

DR. T. RICHARDSON, of New Orleans. Looking over the statistics of the Charity Hospital of New Orleans, I find that in the last five years there have been thirty-one cases of penetrating knife wounds of the abdomen, of which twenty-four recovered and seven died. There were thirty-three cases of gun-shot wound of the abdomen with thirteen recoveries and twenty deaths. Laparotomy was performed in one of the fatal cases of gun-shot wound; all the other were treated on the expectant plan.

DR. D. HAYES AGNEW, of Philadelphia. I have very strong convictions in regard to laparotomy. I believe that where there is a reasonable degree of evidence that there is a penetrating wound of the abdominal wall, especially if a shot wound, it is the surgeon's duty to make an exploratory incision. We are not to be deterred by the possibility of some legal technicality if the case should come into court. We are to do our duty without reference to the consequences.

(To be continued.)

SEVENTY-THIRD ANNUAL REPORT OF THE  
MASSACHUSETTS GENERAL HOSPITAL AND  
MCLEAN ASYLUM.

The report of the Massachusetts General Hospital and the McLean Asylum, for 1886 (the seventy-third annual report), contains the usual items of information.

The whole number of patients received at the Hospital in the course of the year was 2,580—1,142 men, 948 women, and 190 children—of whom 21 were under two years old. For the year 1885 it was 2,327—1,351 men, 794 women, and 182 children—33 of whom were under the age of two. The average number of patients in the Hospital was 173 (males 99, females 74), of whom, on the average, 152 had free beds. Last year, the average number of patients was 167, with an average of 150 free beds. The number of new patients treated in the out-patient department during the year was 17,925. At the Convalescent Home, there were, in the course of the year, 308 patients.

The proportion of deaths to the whole number of results among those treated in the Hospital was 7.53 per cent. The number of patients received on account of accident was 471. The average number of paying patients was 21: Americans, 15; foreigners, 6. The average number in private rooms was 6.1. The average number of free patients was 152: Americans, 75; foreigners, 77. The average time of paying patients was 2.78 weeks, and that of free patients, 3.72. The proportion of ward beds occupied by free patients was 85 per cent.; by paying patients, 15 per cent. Of the free patients, 12 per cent. were female domestics; 20 per cent. were laborers; 15 per cent. were mechanics; and 9 per cent. were minors. The surgical patients, as usual, exceed the medical in numbers.

There was received during the year \$70,403.71, of which \$65,383 are for the benefit of the Hospital, and \$5,020 for that of the Convalescent Home. From the report of the Treasurer, it appears that the ordinary expenses of the Hospital, Asylum, and Convalescent Home, taken together, exceed the entire income of

the Corporation by the sum of \$11,730.21. This amount, with the sum of \$12,679.93 for permanent improvements at Belmont, and \$17,342.41 for the construction of the second sanitary tower at the Hospital, makes an aggregate of \$41,759.55. This sum, representing the excess of the ordinary and extraordinary expenses of the Hospital over its income, has been drawn, as usual, from the permanent general invested funds of the Hospital. The excess of the ordinary expenses over the income is substantially due to the number of free beds at the Hospital. That this deficit should cease to exist, without curtailing the number of free beds, large additions to the subscriptions to free beds are considered necessary by the trustees. There were quite numerous changes in the medical and surgical staff during the year, among which may be mentioned the resignation of Dr. Henry J. Bigelow, after a service of forty years, and the declining of a re-election by Dr. George C. Shattuck, after a service of thirty-six years. Dr. John W. Pratt succeeded the late Dr. Whittemore in the administration.

In regard to the beneficent work of the year at the McLean Asylum for the Insane, the Superintendent, Dr. Cowles, reports that the numbers admitted, discharged, and recovered, and the daily average under treatment, differed by only one or two persons from that of last year. With one less recovery, the percentage of recoveries on admissions was increased two-tenths. The number of voluntary cases admitted was one-third of all the admissions. The percentage of recoveries furnished by this class of patients was eight less than its due proportion, showing that no advantage in this regard is derived from this class.

The average number of patients under treatment for six years, and the average cost per week for each patient, are shown by the following figures:

	1881.	1882.	1883.	1884.	1885.	1886.
Daily average number of patients, . . . . .	149	155	164	166	171	169
Average cost per week, . . . . .	\$16.92	\$17.02	\$16.16	\$16.00	\$15.72	\$15.84

This includes all extraordinary expenses for repairs and alterations and improvements.

The little difference in the general results of the last two years emphasizes the fact that the asylum is doing about the maximum amount of work, with its wards fully occupied. Its general condition, and the hope, as well as need, of having new buildings at Belmont in the near future—the erection of which is only delayed by the lack of funds—are, in many ways, limitations to present progress.

The event of the year has been the graduation from the Training School, established a few years ago, of the first class of trained nurses, sixteen in number. A composite photograph of this class shows a high average of intelligence and character, as revealed in the features. Such nurses, trained in attendance upon the mentally afflicted, cannot fail to be of much use in the hospital, and a real blessing to the community at large. Here is a noble field for intelligent, healthy, young women longing for a vocation.

The Treasurer gives the gratifying information that the receipts at the McLean Asylum exceeded the expenses, which were \$144,374, by \$4,004.

#### IS THE FREE DRINKING OF WATER WITH MEALS INJURIOUS?

THE older physiologists generally answer the above question in the negative; most recent authorities see little evil in a moderate—not excessive—ingestion of drinks at meal-time.

Dr. A. W. P. Leuf has published an article in the *Medical News* (April 16, 1887), in which he advocates the free use of water with meals. When ingested during meals, he says, water does good by washing out the digested food, and by exposing new surfaces to be acted upon by the gastric juice. Pepsin is a catalytic body, and a given quantity will work indefinitely, provided the effects of its work are constantly removed, so as to enable this catalytic body to come in contact with new material.

Dr. Leuf also finds that water drank freely before meals is beneficial by thinning and washing out accumulated mucus, increasing the fulness of the capillaries of the stomach, and favoring peristalsis of the whole alimentary tract. The clean hyperæmic mucous membrane is then in excellent condition to receive food. Moreover, the stomach is distended by the drink, and its rugæ to some extent obliterated. Dr. Leuf has found by repeated vivisections of animals, and post-mortem examinations of healthy men dying by violence some time after meals, that the shape of the stomach varies with the degree of distension. The empty stomach, called the "tubular stomach," is of small calibre, the mucous membrane being deeply corrugated or folded, the muscular coat contracted and thickened. Gaseous distension, though frequently observed, is not the rule, nor is it strictly physiological. The flow of mucus is constant, and is especially noticeable during the intervals between the periods of digestion. Mucus is normally secreted during the night, and the gastric walls in the morning are covered with a thick, tenacious coat of this substance. If food enters at this time, it will become covered with a coating of this tenacious mucus, which may for a time hinder digestion. The tubular contracted stomach with its puckered mucus lining, always normal in the morning before breakfast, is not in a condition to receive food. The mucus it contains interferes with proper digestion, and its firm contraction is an obstacle to the free circulation of blood through its vessels. A goblet of water taken before breakfast washes out this mucus, partly distends the stomach, wakes up peristalsis, and thus prepares the alimentary canal for the morning meal. He finds, moreover, that non-irritating liquids pass directly through the tubular stomach; they do, likewise, if the stomach contains food, and in such cases pass along the lesser curvature, they neither mingle with the alimentary bolus, nor impair

the action of gastric juice in the latter. Cold water should be given to those who have the power to react, and hot water to all others. In chronic gastric, especially catarrh, it is very advantageous to drink warm or hot water before meals, and salt may be added with additional benefit in almost all instances.

#### TREATMENT OF ACUTE PHTHISIS.

LEPINE, Professor of the Faculty of Medicine of Lyons, treats acute miliary tuberculosis with large doses of iodide of sodium, fifteen to twenty grammes daily to an adult patient being, in his estimation, not too much. He gives this salt, as constituting, according to him, the most efficient "microbicide" in this disease, and claims good results therefrom. "The iodide of potassium," he says, "has rendered incontestable service in tuberculous meningitis, as many competent observers have proved, as also in the fever of phthisical patients, when this is due to a fresh crop of granulations. Quite recently, Gosselin has vaunted iodoform, and has found that the evolution of tuberculous lesions is retarded, and even prevented thereby." Lepine prefers the sodium to the potassium salt, as being better borne by the economy in the large doses required.

Recent experiments of Raymond and Artaud indicate the possibility of benefits being derived from the prolonged administration of tannin in acute phthisis. These experimenters claim to have rendered hæmorrhagic to inoculation by tubercles by subjecting them for a month to daily doses of fifteen grains of tannin. They also affirm that they have witnessed decided amelioration, in the acute forms of phthisis, from the administration of from fifteen to seventy-five grains of tannin.

#### MEDICAL NOTES.

—Five hundred and seventy-six deaths from cholera were registered at Buenos Ayres during the two months ending February 28, 1887. It is reported that cholera disappeared in the month of March.

—A man died at Key West on the 20th inst., from yellow fever, and his wife and sister are both ill with the same disease. Tampa, the nearest connecting point by sea, has been quarantined against Key West.

—Doctor's office, St. Louis. Enter a lady with a sick dog. "My dear Dr. —, you must not be angry with me, but won't you please cut off this tumor on poor Fannie's flank?" "Well, madam, I would do anything to oblige you, but this is a little out of my line. Why don't you take the dog to a veterinary surgeon?" "But, Doctor, those veterinaries are so expensive. I supposed you could do it just as well." — *St. Louis Republican*.

—In the preface to the last edition of an English medical work entitled "What to Do in Cases of Poisoning," the author, Dr. Murrell, says: "This work

has reached a fifth edition, but it is not my fault, and I disclaim all responsibility in the matter. I am told that it has been the means of saving many lives, and I have no doubt this is true, for I hear that a gentleman who thought of poisoning himself, changed his mind on reading the directions for treatment."

—The *Lancet* quotes Dr. Gluzinski, writing in a Polish journal, as stating that, in cases of catarrhal jaundice, he has found excellent results follow the treatment recommended by Krull, namely, the repeated injection into the bowel of large quantities of cold water. This increases the peristaltic action of the intestines, and removes any mechanical obstacle to the flow of bile. Again, as has been shown by Röhrig and Mosler, who injected large quantities of cold water into dogs, the bile is thus rendered both more liquid and more abundant, so that it more easily overcomes any obstruction. At first, water at 59° F. is injected into the bowel until the patient complains of a feeling of distension in the abdomen. He is then made to retain it as long as possible. Most patients manage to retain two litres for from a quarter to half an hour. The next day the enema is repeated, but with water about 4° higher. The temperature is again raised on each succeeding day, but when 72° have been reached, no further increase is made. The reason of the increase is that the repeated introduction of cold water is apt to irritate the mucous membrane of the bowel. Altogether, four or five enemata are sufficient to produce the desired effect. The increase of the biliary secretion may be judged of by the color of the feces. Of course, the diet is attended to, in order to prevent a recurrence of the affection.

#### BOSTON AND NEW ENGLAND.

—At the annual meeting of the Norfolk District Medical Society, held May 10th, the following officers were elected: President, Dr. William P. Bolles, Roxbury. Vice-President, Dr. G. D. Townshend, Roxbury. Secretary and Librarian, Dr. S. A. Potter, Roxbury. Treasurer, Dr. E. G. Morse, Roxbury. Commissioner of Trials, Dr. J. Stedman, Jamaica Plain. Nominating Councillor, Dr. O. F. Rogers, Dorchester. Censors, Drs. H. C. Ernst, Jamaica Plain; H. W. White, Roxbury; H. W. Broughton, Jamaica Plain; S. M. Crawford, Roxbury; F. W. Vogel, Roxbury. Councillors, Drs. O. F. Rogers, Dorchester; G. E. Meeuen, Roxbury; G. W. Clement, Roxbury; J. W. Chase, Dedham; E. L. Farr, Roxbury; G. K. Sabine, Brookline; G. D. Townshend, Roxbury; C. A. Bemis, West Medway; C. F. Withington, Roxbury; G. O. Allen, West Roxbury; W. C. B. Fifield, Dorchester; N. Call, Roxbury; A. D. Kingsbury, Needham; E. P. Gerry, Jamaica Plain; H. R. Stedman, Roslindale.

—*A propos* of the recent resolutions adopted by the Suffolk District Medical Society, regarding the system of milk delivery in and around Boston, a correspondent writes—"There is a decided need of an inspector of bungs, or the stoppers used in the top of milk cans. This source of contamination seems to be

completely overlooked, but after careful and studious selections of samples of milk, in widely different localities in Boston, during three years or more, I have come to the conclusion that the wooden stoppers are not renewed as often as needed to insure a wholesome, pure taste to the milk. Some of the samples I have tried to use as drink were so bad that no other taste could be found that would assist in smuggling the article into the stomach. Scalding the bungs would perhaps be of a certain advantage, but as cheap as wood can be had, there need be no excuse to keep the bung in use after it has that sour wood taste, such as is often smelled in oysters transported from fifty to one hundred miles away from the salt water and allowed to remain from twenty-four to forty-eight hours in the wooden keg or pail until sold. The taste of the wood in each of the above cases, is identical, and does not take a very keen observer to detect it. Milk distributed in the smaller cities and towns has none of this bad taste."

#### NEW YORK.

—Dr. Cyrus Edson, of the Health Department, lately seized two car-loads of tainted meat, which it was intended to manufacture into bologna sausages.

—By the will of the late Oliver Hoyt, the Methodist Episcopal Hospital, of Brooklyn, receives a gift of \$20,000.

—Dr. Charles L. Dana has been elected Chairman of the Section on Theory and Practice of the New York Academy of Medicine.

—At a meeting of the Board of Charities and Correction, held May 19th, Dr. Charles E. Simmons was elected President, and he is probably the first medical President that the Board has ever had. Dr. Simmons is said to have several plans in view for developing improvements in the management of the interests in charge of the commissioners, among which are the establishment of a model prison on Riker's Island, and the carrying out of the cottage system in the treatment of the insane on the farm at Central Islip, Long Island, recently purchased by the city authorities for that purpose.

—Governor Hill has nominated Dr. Charles Phelps for Health officer of the port of New York, *vice* Dr. Wm. M. Smith, whose term of service has expired, and who will be remembered to have suffered, justly or unjustly, in reputation, from the developments of the recent rag disinfection suits brought in that city. Dr. Phelps is well and favorably known, and his appointment seems to have met with favor from the medical profession.

#### CHICAGO.

—*Regulation of the Practice of Medicine in Illinois.*—Illinois enjoys the distinction of having led our States in the enactment of laws regulating the practice of medicine in a good way—that is, a good way in the eyes of some, perhaps most, of the regular and reputable profession. Whether or not a majority of

its own medical men thought the law a good one, and that it was "driving out the quacks," certainly public sentiment elsewhere regarded this as a fact, hence laws similar in character were enacted in other States. Certainly it has been more difficult than formerly, in Illinois, for irregular practitioners to ply their vocation. Still many quacks of various sorts and kinds — especially those who had practised ten years at the time of the adoption of the law — have thriven in spite of the law and the State Board of Health, which latter is specially charged with the execution of the law. One or two decisions of the courts have made it nearly useless for the Board to attempt to discipline men for any species or degree of irregularity, provided the victim resisted through the courts. An amendment to the law was introduced into the Legislature, now in session, the effect of which would be to stop flagrant quackery at least. This amendment has just now been defeated in the lower house by a considerable majority, it is said through the influence of a powerful lobby of quacks and their friends. The real cause of the defeat of the measure is said to be the fact that it was a blow apparently aimed at the just now very prevalent delusion of the metaphysical cure. It was a mistake on the part of the Board to suppose it could secure a majority of the lower house, to censure even indirectly this new fashionable craze; too many members or influential constituents — men and women — back of them, have already been struck by this particular fog to make such a consummation possible. The haze will probably be passing off two years hence, when the next legislature meets — possibly something better can be done at that time. But the need of a law to protect the community from imposition in this direction will be less at that time, probably, than it is now — if, indeed, the need exists at all, of which there is some question, since there is a truth in the doctrine that as people like to be humbugged by transparent frauds and falsehoods they should be allowed the privilege. Meanwhile, the newest accession to our bench, Judge Tuthill, before he had finished his first month of service, had sent a fellow to jail for a year for imposing on some poor persons as a voodoo doctor, and getting a small fee. This form of remedy seems to be the only thing left. If Judge Tuthill keeps on this way he will make a record.

— The Illinois State Medical Society has just closed an interesting meeting devoted entirely to the business of the society. There was no social feature, the omission being due wholly to the fact that the National Association meets here next month, when the profession and the public will be asked to open their social arms to the visiting profession.

— The profession here is just now contemplating the outrageous position into which a physician may be placed by an unscrupulous advertiser. The vender of a sulphuretted mineral water seized the opportunity of the present popularity of the rectal injections of gas for consumption, to improve his trade by a flaming

advertisement of the water, with a cut of the apparatus used, and fulsome statements that the gas from this water was a sure cure, etc. From reports of a meeting of the Medical Society, he learned the names of a number of physicians who were using the measure, and embodied their names in the advertisement in such a way as to make it appear that they endorsed in full the statements it contained. The performance has been denounced in a card by all the physicians whose names were used, but this only slightly counteracts the effect of the outcry. It is interesting, anent this subject, to note how generally the profession here is now reaching the conclusion — the only one that ever ought to, or could logically have been formed — that the most desirable, as the only definite and exact way to secure the sulphuretted hydrogen for this kind of medication is through the well-known artificial compound with the sulphide of sodium, and not by means of any natural water.

— The Board of County Commissioners has recently removed the appointment of the attending staff of the Hospital from the domain of politics. It has voted the present staff shall remain during good behavior, and that any vacancies in its membership shall be elected by an Advisory Board of five medical men, whom it has appointed. In case of a vacancy, the staff is to nominate three persons from whom the Advisory Board is to elect one. The Advisory Board, as at present constituted, has a representative from each of three regular medical colleges. The full list is as follows: Drs. W. H. Byford, H. A. Johnson, A. Reeves Jackson, A. H. Foster, and R. G. Bogue. For a number of years past it has been the custom of the County Board to change the Hospital staff annually, each one of the five newly elected members of the Board having appointment of one member of the staff, so that the staff was not only constantly changing, but changing according to the personal and political whims of laymen.

### --- **Miscellany.**

#### THE TREATMENT OF CHOREA.

A NUMBER of recent contributions upon this subject are summed up in the *London Medical Record*. Owen noticed in a case of chorea, treated with four and one-half minims of Fowler's solution three times daily (the dose afterwards increased to five minims), one month after the commencement of the arsenic, bronzing of the nipples, armpits and neck occurred; this became more marked during one month in some of the parts affected, and then gradually diminished. Cases of bronzing following the use of arsenic are not common. Frühwald, of Vienna, has treated cases of chorea with arsenic, administred hypodermically and by the mouth, and compared the results. He gave one to three minims of Fowler's solution hypodermically, and considered that the results were more favorable than dosage by the mouth. Improvement began at the end of a week, and cure was complete — that is, there was absence of incoördination — at the end of

three or four weeks. Joffroy has had good results in the treatment of chorea with chloral. He gave to children of ten years of age one drachm daily, and to children of six to eight, forty-five grains daily, divided into three doses. The treatment was continued for from two weeks to two months. Free cured two cases of chorea, which had been unsuccessfully treated by other drugs, with extract of *cimicifuga*. Nauwerck has published the account of a fatal case of chorea, with the details of a carefully conducted *post-mortem*. The case was one of chorea minor, and died of asthenic pneumonia. To the eye no gross change could be detected in the organs after death, except a few vegetations on the mitral valve. There was a systolic murmur during life. A histological examination showed that the peripheral nerves were quite healthy, and that in the central nervous system there were three kinds of changes. In the medulla oblongata and the pons Varolii there were areas in which there was a great amount of perivascular infiltration, and other areas in which there were slight hemorrhages. Both these kinds of changes have been described by Dickinson. No capillary emboli were found. The third change described by Nauwerck is a degeneration of nerve-fibres, chiefly in the cervical region of the spinal cord. The change consisted in an irregular swelling of the axis-cylinder in parts (the so-called "hypertrophy,") and in fatty degeneration with complete disappearance of some axis-cylinders. These changes did not occupy any particular strand or strands of the cord, but were irregularly distributed. According to Nauwerck, their presence might account for the incoördination.

#### CASES OF LETHARGIC TRANCE.

DR. T. MORE MADDEN, writing in the *Medical Press and Circular*, April 27th, on the subject of lethargy or trance, dissents from the general opinion that this phenomena is so rarely met with as to be of little medical importance. He has no doubt that these conditions are of far more frequent occurrence than is generally supposed, and has, moreover, had reason to know that death is occasionally so exactly thus counterfeited, that there is good cause for fearing the probability of living interment in some cases of hasty burial.

He gives five cases which have come under his personal observation, as follows:

"The first is an instance of so-called hysteric trance: A young lady, Miss R., apparently in perfect health, went into her room after luncheon to make some change of dress. A few minutes afterwards she was found lying on her bed in a profound sleep, from which she could not be awakened. When I first saw her, twenty-four hours later, she was then still sleeping tranquilly, the decubitus being dorsal, respiration scarcely perceptible, pulse 70, and extremely small; her face was pallid, lips motionless and the extremities very cold. At this moment, so death-like was her aspect, that a casual observer might have doubted the possibility of the vital spark still lingering in that apparently inanimate frame on which no external stimulus seemed to produce any sensorial impression, with the exception that the pupils were normal, and responded to light. Sinapisms were applied over the heart and to the legs, where they were left on until vesication was occasioned without causing any evi-

dence of pain. Faradization was also resorted to without effect.

"In this state she remained from the evening of the 31st of December until the afternoon of the 3d of January, when the pulse became completely imperceptible, the surface of the body was icy cold, the respiratory movements apparently ceased, and her condition was to all outward appearance undistinguishable from death. Under the influence of repeated hypodermic injections of sulphuric ether and other remedies, however, she rallied somewhat, and her pulse and temperature again improved. But she still slept on until the morning of the 9th, when she suddenly woke up, and to the great astonishment of those about her called for her clothes, which had been removed from their ordinary place, and wanted to come down to breakfast, without the least consciousness of what had occurred. Her recovery, I may add, was rapid and complete.

"The next case of lethargy that came under my notice was that of a boy, who, after an attack of fever, fell into a state of complete lethargic coma, in which he lay insensible between life and death, for forty-seven days. In this case, as in the last, the patient ultimately recovered perfectly.

"In a third instance of the same kind in a lady under my care, the patient, after a lethargic sleep of twenty-seven days, recovered consciousness for a few hours, and then relapsed into her former comatose condition, in which she died.

"The fourth case of lethargy which I have seen was like the first, a case of trance which lasted for seventy hours, during which the flickering vital spark was only preserved from extinction by the involuntary action of the spinal and nervous centres. In this instance the patient finally recovered.

"The fifth and last instance of profound lethargy that has come within my own observation, occurred last autumn in the Mater Misericordie Hospital, in the case of a young woman under the care of my colleague, Dr. Boyd. In that instance, despite all that medical skill could suggest or unremitting attention could do, it was found impossible to arouse the patient from the apparently hysterical lethargic sleep in which she ultimately sank and died."

#### OBITUARY. WILSON FOX, M.D., F.R.C.P., F.R.S.

Our English exchanges bring tidings of the death of this renowned clinical teacher, which occurred from pneumonia, with heart-failure, the latter the result of long-standing cardiac disease, on the 3d of May, in the fifty-seventh year of his age. Dr. Fox was a descendant of the famous Quaker family of that name. He was the son of an eminent manufacturer at Wellington, and was educated first at Bruce Castle, Tottenham, and afterwards at University College, London; he took the degree of B.A. in the University of London, and he subsequently entered the medical faculty of University College. Among his fellow-students were Sir Joseph Lister, Sir Henry Thompson, Sir William Roberts, Dr. Russell Reynolds, and Dr. Graily Hewitt. After a distinguished career as a student, he took the degree of M.B. in 1854, and that of M.D. in the following year. He was House-Physician at University College Hospital, and subsequently held a similar appointment in the Edinburgh Royal Infirmary. He then went abroad, and spent a considerable time in Berlin, Vienna, and other centres of German thought, where he had the advantage of studying under Virchow, Koelliker, and other eminent teachers. On his return he became physician to the North Staffordshire Infirmary, and soon acquired a considerable practice in Newcastle-under-Lyme. Ill-health induced him to resign his appointment, and to return to London, partly in order to place himself under medical care. From this indisposition he completely recovered, and was ap-

pointed Assistant-Physician to University College Hospital in 1861, at the same time succeeding Sir William Jenner as Professor of Pathological Anatomy.

In 1866, he was elected a Fellow of the College of Physicians, and a few years afterwards, a Fellow of the Royal Society. In 1877, he exchanged the chair he held for that of Holme Professor of Clinical Medicine, the duties of which he performed up to the time of his death, and where he made perhaps his strongest impress, through his admirable qualities as a teacher, on the medical mind of his country. In 1875, he was appointed Physician-Extraordinary, and, at a subsequent date he became Physician-in-Ordinary to Her Majesty.

Dr. Fox's contributions to scientific medicine were numerous and important. One of his earliest researches was on the development of muscular tissue, published in the *Philosophical Transactions*. Another was concerned with the origin and structure of cystic disease of the ovary. His attention was afterwards given specially to diseases of the stomach and of the lungs, and he wrote on both subjects for the *System of Medicine*, edited by Dr. Russell Reynolds. His articles on diseases of the stomach were afterwards republished in an enlarged

form as a separate work. The work, however, for which he was best known was his research into the nature of tubercle; to this he devoted the best energies of his life; for many years, even when he was almost alone among English pathologists, he stuck manfully to his thesis that tuberculosis was a peculiar and special process, and that it was not merely ordinary chronic inflammation, as was the popular German opinion, reflected in this country, until Koch's researches were published. Dr. Fox's experimental researches led him to believe that tuberculosis might be produced by the inoculation of indifferent material, and he expressed this opinion in a lecture delivered before the Royal College of Physicians. The publication of Koch's results, while confirming the correctness of his views as to the special characters of the tubercular process, necessitated a re-modelling of his views as to the etiology of the disease. It was owing to this cause that the publication of his great work on diseases of the lungs, at which he had worked with extraordinary industry for many years, was postponed. It may be hoped that the enormous mass of materials which he had brought together, and the large collection of drawings which he had prepared to illustrate it, may not be lost to the world.

## REPORTED MORTALITY FOR THE WEEK ENDING MAY 14, 1887.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2,024: under five years of age 705; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fevers) 515; consumption 283; lung diseases 276; diphtheria and croup 110; diarrheal diseases 80; measles 37; scarlet fever 28; malarial fever 22; cerebro-spinal meningitis 13; whooping-cough nine; erysipelas nine; typhoid fever nine; puerperal fever three; small-pox (Cambridge) one. From scarlet fever, New York 11, Brooklyn seven, Boston, Baltimore, District of Columbia, Pittsburgh, Worcester, New Bedford, Salem and Brockton one each. From malarial fever, New Orleans 10, New York six, Brooklyn four, Richmond and Providence one each. From cerebro-spinal meningitis, New York three, Fall River two, Richmond, Pittsburgh, Worcester, Lowell, Somerville, Brockton and Fitchburg one each. From whooping-cough, New York three, Baltimore two, Boston, Richmond, Pittsburgh and Worcester one each. From erysipelas, New York three, Brooklyn two, Boston, Baltimore, Portland and Fall River one each. From typhoid fever, New York, Boston and Baltimore two each, New Orleans, District of

Columbia and New Haven one each. From puerperal fever, New York, Pittsburgh and Nashville one each.

In the 21 cities and greater towns of Massachusetts, with a population of 1,019,014 (population of the State 1,941,465) the total death-rate for the week was 19.28 against 19.29 and 18.54 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,245,000, for the week ending April 30th, the death-rate was 20.6. Deaths reported 3,647: infants under one year of age 708; acute lung diseases (London) 338; measles 264; whooping-cough 132; scarlet fever 51; diphtheria 43; diphtheria 25, fever 15.

The death-rates ranged from 10.5 in Derby to 35.4 in Cardiff; Birmingham 21.1; Blackburn 30.8; Hull 17.6; Leeds 19.1; Leicester 15.7; Liverpool 27.0; London 18.3; Manchester 27.5; Newcastle-on-Tyne 22.6; Nottingham 18.9; Plymouth 16.9; Sheffield 26.4.

In Edinburgh 20.2; Glasgow 24.9; Dublin 39.3.

The meteorological record for the week ending May 14, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 14, 1887, TO MAY 20, 1887.

TAYLOR, MORSE K., surgeon. Retired from active service May 14, 1887. S. O. 111, A. G. O., May 14, 1887.

WHITE, R. H. Promoted to be surgeon with the rank of major, to take effect from May 14, 1887.

HALL, JEO. D., captain and assistant surgeon. Granted leave of absence for one month, with permission to apply for his month's extension. S. O. 74, Department of Colorado, May 11, 1887.

SUTER, WILLIAM N. Appointed assistant surgeon, with the rank of first lieutenant, to rank as such from May 16, 1887.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE TWO WEEKS ENDING MAY 21, 1887.

GRAVATT, C. U., surgeon. Detached from the United States Steamship "Michigan."

LUMSDEN, G. P., passed assistant surgeon. Ordered to the United States Steamship "Michigan."

ASHBRIDGE, RICHARD, passed assistant surgeon. Detached from the Naval Academy and to the Practice Ship "Constellation."

STREETS, THOMAS H., passed assistant surgeon. Promoted to surgeon.

CURTIS, I. W., passed assistant surgeon. Ordered to the "Quinnchaug."

BAKER, J. W., passed assistant surgeon. Ordered to the Hospital, Chelsea, Mass.

PRICE, A. F., surgeon. Ordered to board duty, Annapolis, Md.

GRAVATT, C. U., surgeon. Detachment from "Michigan" revoked.

LUMSDEN, G. P., passed assistant surgeon. Orders to the "Michigan" revoked.

SKIFFERED, C. A., surgeon. Ordered to the "Quinnchaug."

PEIRSON, R. C., surgeon. Detached from the "Saratoga."

FAIRWELL, W. G., surgeon. Ordered to the "Saratoga."

DIXON, W. S., surgeon. Ordered to special duty, Baltimore, Md.

ROGERS, B. F., surgeon. Ordered to the Marine Rendezvous, N. Y.

WELLS, HOWARD, passed assistant surgeon. Ordered to the "Jamestown."

WISS, J. C., surgeon. Detached from the "Jamestown."

HARVEY, H. P., surgeon. Ordered to the "Iroquois."

WAGGNER, J. R., surgeon. Detached from the "Iroquois."

WHITE, DR. S. SVART, of Frederick, Md., Commissioned assistant surgeon in the Navy, May 19th.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDING MAY 14, 1887.

FISKENVEX, C. S. D., surgeon. Detailed as chairman of board for physical examination of cadets, Revenue Marine Service, May 13, 1887.

STONER, G. W., surgeon. To proceed to Delaware Breakwater as inspector, and to New York and Philadelphia, to inspect unseaworthy property, May 12, 1887.

IRWIN, FAIRFAX, passed assistant surgeon. Detailed as recorder of board for physical examination of cadets, Revenue Marine Service, May 13, 1887.

TATTIE, J. B., assistant surgeon. Relieved from duty at Baltimore, Md.; ordered to Marine Hospital, St. Louis, Mo., May 13, 1887.

#### SOCIETY NOTICE.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the Society will be held at the Medical Library, 19 Boylston Place, on Monday evening, June 6, 1887, at eight o'clock. Readers: Dr. W. C. Holyoke, "An Outbreak of Typhoid Fever in a Children's Home." Dr. P. C. Knapp, "Cerebral Infantile Paralysis."

CHARLES P. STRONG, M.D., Secretary.

#### DEATH.

Died in Hopkinton, Mass., May 6, 1887, George Augustus Warren, M.D., M.M., S.S., aged sixty-eight years.

#### BOOKS AND PAMPHLETS RECEIVED.

Annual Address delivered before the American Academy of Medicine at Pittsburgh, Pa., October 12, 1886. By R. S. Sutton, A.M., M.D., President of the Academy.

A New Clothing Case for the Soldier. By W. Thornton Parker, M.D., Newport, R. I., late A. A. Surgeon U. S. Army. (Patent applied for.) Newport, R. I. 1887.

Twenty-Seventh Annual Report of the Medical Superintendent of the State Asylum for Insane Criminals, Auburn, N. Y. For the Year ending September 30, 1886. 1887.

A CASE OF HYSTERECTOMY FOR THE RELIEF OF PYELITIS FROM OBSTRUCTION.<sup>1</sup>

BY A. T. CADOT, M.D.,

*Surgeon to the Massachusetts General, and to the Boston Children's Hospital; Clinical Instructor in Genito-Urinary Surgery in Harvard University.*

BEFORE proceeding to the consideration of the case I have to report, I wish to allude briefly to the post-mortem examination of another case, which I saw during the last days of life, and which illustrated very well the condition to which my patient might have expected to come, had she not been relieved by operation.

In August, 1886, I saw a lady of over seventy, who had, for years, carried a fibroid tumor of the uterus of moderate size. Many years before, she had suffered much from it, but it had finally become quiescent, and had gradually hardened and settled down into the pelvis. She had been troubled for a long time with frequency of micturition, and about a year and a half before I saw her, after a fall, she had an acute attack of pelvic inflammation, with an aggravation of urinary symptoms.

The urine, at this time, became loaded with pus, and during the year before her death, she on several occasions passed small bits of phosphatic material. The pain in the bladder gradually increased in severity, urination became extremely frequent, with almost constant tenesmus, and she finally died in a uræmic condition, with suppression of urine.

For the notes of the autopsy, I am indebted to Dr. H. C. Ernst, who made the examination.

He found that the fibroid, which sprang from the anterior uterine wall, and weighed four-and-a-half pounds, was almost completely calcified, and was so matted down into the pelvis by inflammatory adhesions, that it was with great difficulty that it could be dissected out, with the bladder and rectum adherent to it.

The bladder was very much contracted, and the walls thinned, evidently by pressure. It contained but a few drops of thick, ammoniacal urine.

The urethra was normal, but the ureters, in their passage over the brim of the pelvis, had been pressed upon by the uterine tumor, so that above this point they were much dilated, having the calibre, on both sides, of a very large lead pencil. Their walls were much thickened and congested, and a little pus was found in each.

The kidneys were large and soft, very dark-red in color, with their capsules extremely adherent. The pelvis were much dilated, and full of masses of phosphatic material.

The secreting substance of the kidneys was diminished in amount, of a dull red color, with well-marked Malpighian corpuscles. The proportions between the medulla and cortex were very little altered.

We had here, then, an obstruction of the ureters by the pressure of a uterine fibroid, leading to chronic pyelitis, and finally, to pyelo-nephritis and death. In this case, the symptoms of obstruction to the ureters came on late in the history of the fibroid, and were possibly due to the settling of the tumor into the pelvis, and to the strong adhesions which it contracted in that position.

In the case which I have now to report, pyelitis occurred as an early symptom, while the removal of the tumor was yet possible.

Christine McL., aged twenty-five, a pale and thin young woman, was referred to me by Dr. J. E. Garland, of Gloucester, in December, 1886. She had a tumor, about the size of a child's head, occupying the lower median part of the abdomen, and projecting deep into the pelvis in Douglas's pouch. The os uteri was to be felt anteriorly, high up, and the body could be indistinctly made out behind the pubes. Above this, a little to the right of the umbilicus, was a second tumor, about as large as a small orange, somewhat movable, but seemingly attached by pedicle to the larger growth below.

In neither of these tumors could any fluctuation be detected, but over the whole anterior surface of the larger one, was a layer of fluid, which the passage of a catheter showed to be in the bladder, which was flattened and pressed up against the abdominal wall.

The patient discovered the existence of a tumor about two years before, since which time its growth had been slow, but steady. At first there had not been much pain, but within the last six months she had had intermittent attacks of abdominal and pelvic pain, which were brought on usually by exertion, and incapacitated her from work.

Micturition had lately been much increased in frequency, often coming with intervals of but half-an-hour. The urine was alkaline, with a specific gravity of 1012. It contained considerable sediment, which consisted of pus, a little blood, bladder and vaginal epithelial cells, and triple phosphate crystals.

The diagnosis was of either a fibroid, or an extremely tense, thick-walled cyst, wedged behind the uterus. The smaller tumor above was thought to be an accessory cyst or fibroid. The condition of the urine, and the character of the micturition, was ascribed to cystitis from pressure. At my advice, she entered the Massachusetts General Hospital.

Owing to absence from the city, I did not see her again for two weeks, when, on my return, I found her in bed in a febrile condition, with evening exacerbations of temperature. She was suffering from pretty severe abdominal pain, and there was considerable tenderness, especially about the small tumor. It seeming probable that suppuration was starting in connection with one or other of the tumors, the patient was etherized, and the abdomen was opened. It was found that the large growth was a fibroid, starting from the posterior uterine wall, and firmly fixed in the pelvis, from which it could not be dislodged by any ordinary force. The smaller one was a little ovarian cyst, which, in consequence, apparently, of the pressure of the fibroid on its pedicle, was in a sloughing condition.

This cyst was removed, and, in view of the feeble, feverish state of the patient, it was thought best, in the absence of special indications, to leave the fibroid. The other ovary was sought, but was fixed so deeply in the pelvis, behind the uterine tumor, that it could not be removed. The fever now disappeared, and the patient recovered quickly from this operation.

During her stay in bed, with the aid of bladder irrigation, the urine lost its alkalinity, and the frequency of micturition came down to about what is normal. Before she was able to be up, however, she began to have pain through the left side of the back, and in the lower part of the abdomen on that side.

<sup>1</sup> Read before the Association of Genito-Urinary Surgeons, at its meeting, May 17 and 18, 1887.

It was now noticed that the pus, which was quite abundant, came intermittently, so that while one passage of urine was almost clear, the next would contain perhaps half-an-ounce of sediment. This made it evident that the bladder must be reasonably free from inflammation, and Professor Wood now made a second thorough examination of the urine, and found evidence that chronic pyelitis was present.

The varying character of the urine showed that probably but one kidney was as yet affected, and the pain in the left side of the back pointed to that kidney as the one at fault. No enlargement of the organ could be discovered. The character of the fibroid and the way in which it pressed down into the pelvis put it almost beyond doubt that that was causing obstruction of the ureter, and consequent pyelitis.

The condition being explained to the patient, she understanding that at her age the disease could not be expected to come to a standstill or go backwards, chose the alternative of an operation for the removal of the fibroid.

This was done on March 1, 1887. An incision was made close alongside of the old cicatrix. In this, as in the former operation, considerable care was taken to avoid wounding the bladder. The tumor seemed firmly fixed in the pelvis, but rather through being wedged there, than by reason of any adhesions.

With the vigorous aid of an assistant pressing up from the vagina, it was finally dislodged and lifted out: the pedicle was constricted by the wire of an écraseur, and the mass was cut off. The body of the uterus was removed with the tumor, and only the lower part of the cervix was left. The pedicle was treated extra-peritoneally, the écraseur being left in place.

The shock of the operation was great, but the patient slowly rallied, and made a good recovery, leaving the hospital early in April. The pains in the abdomen and renal region disappeared after the operation, and the urine slowly cleared up, until, when she was last seen, it was but slightly cloudy.

The patient rapidly regained strength, and towards the end of April was talking of going to work, but a longer rest was advised.

#### INTUBATION OF THE LARYNX AT THE BOSTON CITY HOSPITAL.

BY W. H. PRESCOTT, House Surgeon.

IN view of the prominence which intubation has obtained during the last year, a report of the operations which have been done at the Boston City Hospital may be of interest.

When first brought forward, the operation was viewed with disfavor by the visiting surgeons, and it was not until December 30, 1886, that the first one was performed. In November, one of the staff tried to insert a tube, and probably succeeded, but not being satisfied with the child's breathing, he withdrew it, and performed tracheotomy.

On December 30th, the first operation was done without any difficulty, and the case is reported as No. I. Since then, the operation has been done nine times. In most cases, the relief from dyspnea has been as marked as after tracheotomy, and, as is usual after the latter, the patient immediately fell asleep, although some were disturbed by the cough which the string occasioned. At first, the feeling that it would not be possible to extract the tube (if there was urgent dysp-

nea) prevented the cutting of the silk thread which is attached to the tube at the time of insertion, and this thread was probably the cause of two of the accidents which have happened. In two cases the silk was removed, and no trouble arose, and there was no especial difficulty in extracting the tube.

In one case where intubation was attempted, the child stopped breathing, apparently from spasm of the glottis, and tracheotomy was immediately done. In another case it was found impossible, after several trials, to insert the tube. I know of no reason, except lack of skill.

In two of the cases the membrane covered the parts so completely, that the guiding finger could not distinguish one part from another. In these cases, the tube was easily inserted by keeping in the median line, and waiting for the child to gasp.

Of the following cases, Nos. I and IV occurred in the service of Dr. Bradford; Nos. II, III, and V, in that of Dr. Bolles; Nos. IX and X in that of Dr. Gay; and Nos. VI, VII, and VIII, in that of Dr. Post.

CASE I. C. B., five years old. Eight weeks before entrance had scarlet fever, from which he had never fully recovered. December 13th, was taken sick with diphtheria, and entered the hospital on the medical side, December 21st. On morning of December 30th, became cyanosed for a short time, and afterwards had considerable dyspnea. Transferred to surgical side. Physical examination: Well developed and poorly nourished; membrane on pharynx, tonsils, and uvula; dyspnea; retraction of chest-walls during inspiration; loss of voice. Intubation (string left in) gave immediate relief to dyspnea. Was comfortable for sixty hours, when he became cyanosed again. Tube removed, and found to be plugged with membrane. Tube cleaned and replaced (silk not removed). Tube coughed up, and swallowed inside of five minutes. No symptoms referable to the tube, which was never recovered. No return of dyspnea. Much membrane still left in throat. Child very weak. Gradually failed, and died, evidently from exhaustion, January 9th. No autopsy.

CASE II. O. T., three years old. December 24th. Taken sick nine days before entrance. Slight cough, and some croupy breathing. Two days before entrance "choked up." No further history. Physical examination: Well developed and nourished; breathing harsh and croupy; some retraction; membrane in throat. Steam; poultice to neck. Continued fairly comfortable, with occasional attacks of dyspnea (relieved by the vomiting produced by *vin. ipecac.*), until January 1st, when breathing became labored, and intubation was done. Immediate relief to dyspnea. Coughed up considerable mucus. Was comfortable until next morning, when had an attack of dyspnea. Tube removed, and found to be plugged with thick mucus; cleaned and replaced. No return of dyspnea. Death the same day, from infection.

CASE III. A. L., three years old. January 13th. Four days before entrance, slight cough, with some vomiting. Last night, dyspnea and loss of voice. Physical examination: Well developed and nourished; anxious expression; no cyanosis; no retraction; croupy cough; membrane in pharynx. Steam; stimulants, *tr. ferri chloridi*, gr. v., *t.i.d.* Comfortable until 15th, when breathing became labored. Retraction. Intubation. Much relief (string left in). Next day, restless. Tube coughed up; replaced. Patient quiet and comfortable until 18th, when had "choking spell." Tube

removed. Breathing easy for a few hours, when it became labored. Tube replaced. Comfortable until 22d, when had another attack of dyspnoea, and when the house-officer arrived, he could not find the tube, but the breathing was easy. Next day, the tube was removed from the rectum. No further dyspnoea; and from this time the child made an uninterrupted and rapid recovery, and was discharged, January 27th, well.

CASE IV. G. F., seven years old. February 13, 1887. Previous history not ascertained. Child brought in suffering from extreme dyspnoea, with marked cyanosis and eruption of measles; loss of voice; retraction of chest-walls during inspiration. Intubation was followed by relief to dyspnoea; quiet for a short time, then became cyanosed. Tube removed. Breathing quiet. Death within seven hours of entrance, due to septicaemia.

CASE V. G. H. February 19, 1887. No history. Physical examination: Fairly developed; poorly nourished; nearly moribund; cyanosis; retraction; no membrane on pillars; pulse weak, rapid, and feeble. Intubation gave relief to dyspnoea. Had several slight attacks of dyspnoea. Death next day, from extension and septicaemia.

CASE VI. A. H., fourteen months old. May 5, 1887. Two weeks ago was feverish. Had nasal discharge but no cough. Gradually grew worse, and yesterday had dyspnoea. Mother at same time noticed membrane in expectorations and in throat. Physical examination: Well developed; fairly nourished; nursing; membrane in throat; nasal discharge; retraction; no cyanosis. Intubation (string left in). Child could still nurse. No further dyspnoea. Death in twenty hours, from septicaemic infection.

CASE VII. W. S., five years old. May 13, 1887. Has had enlarged tonsils, with considerable purulent expectoration, for some years. Four days ago had headache and fever. No vomiting; patches in throat; some dyspnoea; very weak; bowels constipated. This morning lost his voice, and had considerable dyspnoea but no nasal discharge. Physical examination showed well-developed and fairly nourished boy. Pharynx, tonsils, and uvula covered with very thick membrane; retraction; cyanosis; loss of voice. Intubation was followed by relief. Failed gradually. Death in two days, from septicaemia.

CASE VIII. R. M., five years old. May 13, 1887. Five days ago complained of sore throat; was better next day. Two days ago began to cough. No nasal discharge. Was hoarse yesterday, and last night had considerable dyspnoea. This morning lost his voice, and dyspnoea became urgent. Physical examination: Well developed and nourished; considerable dyspnoea; loss of voice; retraction; membrane in throat. Intubation (string removed). Very comfortable for twenty-four hours, when temperature began to rise and an eruption (measles) appeared on body. Respirations became more frequent, but without dyspnoea. Tube was removed on the fifth day. Death that night from exhaustion and complications.

CASE IX. J. D., five years old. May 17, 1887. Has been sick a week; dyspnoea yesterday; nothing further obtained. Physical examination: poorly developed and nourished; membrane on pharynx and uvula; dyspnoea; retraction; loss of voice. Intubation (string removed.) Tube lost next day; considerable dyspnoea; not possible to reinsert a tube. Tracheotomy advised, but not allowed. Since then the

condition of the patient has steadily improved. Dyspnoea persisted for some days with occasional paroxysms of difficult breathing. May 22d his temperature was 99°, pulse 115, respirations 28. Pulse good and strong. Appetite very good. Still in hospital. Nothing has been seen of the tube.

CASE X. H. N., five years old. May 21, 1887. Has been sick a few days with cough and sore throat; some dyspnoea; loss of voice. Physical examination: well developed and poorly nourished. Some retraction; dyspnoea; croupy cough; no voice. Steam, poultices, and brandy prescribed. Soon after entrance had a severe attack of dyspnoea, with cyanosis. Intubation (string retained), gave immediate relief to dyspnoea, but pulse very weak and feeble. Patient soon revived, and was very comfortable until 9 P.M., May 22d, when he seemed to have some obstruction. The tube was removed and reinserted, but the child died within five minutes, without cyanosis. Death in thirty-six hours after entrance from heart failure.

There were two mistakes made in No. I; first, leaving the silk attached; second, in not using a larger tube when it was thought necessary to reinsert one. Dr. O'Dwyer says the tube is never swallowed unless the silk is left in; but in Case IX, the silk was removed, and the disappearance of the tube can be accounted for only on the supposition that it was swallowed.

The swallowing of the tube in Case III may have been due to the silk.

Case IV seemed a hopeless one, and the operation was done without any expectation of saving the child's life, but merely to prevent strangulation.

Case VI was of interest from the fact that the child nursed without difficulty, while the tube was in the larynx.

Case VII seemed hopeless when he came in, but the relief to dyspnoea was very marked.

Case VIII illustrates another point made by Dr. O'Dwyer. On inserting the tube there was an increase in the dyspnoea, and the tube was immediately coughed up. It was found plugged with a piece of membrane, two inches long, the lower part of which was a complete cast of the trachea. On the second insertion no further trouble occurred.

In Case IX the silk was removed, and it is not known where the tube has gone, as he had no symptoms from it.

The treatment has been the same as in tracheotomy, namely: light steam, stimulants, poultice over chest; Dobell's solution<sup>1</sup> as a throat spray. A solution of corrosive sublimate (1 to 15,000) was applied to nasal mucous membrane when there was any nasal discharge. Occasionally small doses of the bichloride of mercury were given. Tincture of digitalis, in small doses, was also given when the urine was scanty, and pepsin to assist digestion, when necessary. At first nourishment was given in enemata, but it was soon found that all the nourishment needed could be given by mouth, without difficulty. Semi-solids cause the least trouble. The first and last "swallows" are the ones that cause the coughing which is always set up, and so it is best to let the child take a mug of milk and drink it rapidly. Although this is a rule, Case VIII was an ex-

Water . . . . . ad Oiv.

ception. This child took liquids best from a teaspoon, while lying on its back. Milk, beef-tea, chicken-broth, ice-cream and custards were given.

The advantages of intubation, as compared with tracheotomy, are: (1) There is no wound, and therefore it will be allowed where tracheotomy might not be. (2) There is not added another source by means of which infection may take place. (3) It can be done more quickly. (4) It is less troublesome both in its performance and its after care. (5) There is not as much discharge. (6) The shock is not as great. (7) No anæsthetic is needed.

The great disadvantage is that the parts below the larynx cannot be kept as free from mucus and membrane as in tracheotomy. Although the fact that intubation can be done more quickly has been put as an advantage, I do not wish to imply that it is a simple procedure. It is not easy, and should be done with a great deal of care and very little force. The statement has been made that it is easier to put a tube into the larynx than into the œsophagus; the experience at the hospital does not bear out the statement.

The method of inserting the tube, as done at the hospital, is as follows: The tube with the silk attached having been put upon the obturator the child should be held upright by an assistant, sitting in a chair facing the operator, with its head held firmly and a little forwards. The gag is introduced on the right side and kept as far back as possible. The operator then introduces his left forefinger into the mouth and passes it downward and backward until he feels the epiglottis; he now passes the tube along the palmar surface of his left forefinger (keeping in the median line) until the tube reaches the epiglottis, when, by an upward movement of the right hand, he can easily put it in place. The left forefinger having been placed on the tube the obturator is withdrawn. After a few minutes the breathing being quiet and the tube having again been felt in position the silk suture may be removed and the patient put to bed.

The number of cases is too small to be of much service in forming an opinion as to the relative value of intubation and tracheotomy from the standpoint of percentage of recoveries; for if the statistics of tracheotomy at this hospital are examined, the percentage of recoveries in any given six months will be found to vary from ten per cent, to thirty-five and even forty per cent.

## REPORT ON HISTOLOGY AND EMBRYOLOGY.

BY CHARLES SEDGWICK MINOT.

DURING the past year there have been several important general publications. An American Journal of Morphology, which promises to be of a high scientific character, has been announced by Ginn, Heath & Co., to be edited by Dr. C. O. Whitman, the leading American embryologist. The first number has been unfortunately delayed, so that only the announcement can be chronicled here. From England we have the beautiful memorial edition of Balfour's works in four handsome volumes. With the utmost generosity the family, to whose care we owe this edition, have distributed numerous copies. The papers and essays gain by collation, and reveal advantageously the genius of the young author. His researches represent a body of work such as few men have accomplished at so

early an age. From the very first he tussled with the great problems of morphology, and sought their solution through embryology, for with the insight of superiority he recognized from the start that embryology is the key to comparative anatomy and evolution. In this direction he continued working, but constantly widened his mental horizon. The growth of his power was well shown by his monograph of elasmobranch fishes, and by his comparative embryology, a great monument to his ability. Balfour's original investigations form the first volume of his works. The "Comparative Embryology" is reprinted as volumes II and III. The fourth volume includes the plates only. The examination of Balfour's contributions to science renders his loss keenly felt. To England he was important, for his charming personality greatly enhanced the influence, which belonged to his abilities. He was one of the most valued and beloved officers of the University at Cambridge. The sad accident on the Aiguille Blanche de Peuteret, in July, 1882, robbed England of her ablest embryologist, a man to whom Darwin wrote, after receiving the second volume of his embryology, "I am proud to receive a book from you, who, I know, will some day be the chief of English Biologists."

But to return from a digression which Balfour's name may well pardon. During the past year Oskar Hertwig has published the first part of his human embryology, which promises to sustain and amplify the author's reputation for comprehensive views and clearness of exposition, qualities which, combined with his gifts of observation and industry, have rendered him eminent. We have as yet only the chapters dealing with the history of the sexual products, maturation of the ovum, impregnation, and so forth; and those upon segmentation; the formation of the germinal layers and of the primitive tissues, and finally Chapters XI to XIII, on the fetal envelopes. Hertwig's views on the morphology of the nesoderm, which he groups under the title of the "beclotheorie" are here admirably presented, so that the discussion of them will be greatly facilitated. I may state in this connection that the "beclotheorie" must be very greatly modified. The chapter on the human envelopes and placenta is thoroughly unsatisfactory, since it is far from offering an adequate synopsis of our present knowledge. Save for these and some minor criticisms the treatise deserves unusual praise, and is, I think, fairly to be called indispensable for every student of embryology.

Wood's "Reference Handbook" contains numerous embryological and histological articles. Although many of the former were written by the present reporter, he ventures to refer to them here, as there has been nothing else so extensive published in English on human embryology since the ninth edition of "Quain's Anatomy," in 1882, and during these five years immense progress has been made in this department of science.

Stöhr's "Lehrbuch der Histologie," is capital; for the use of physicians and medical students it is not only the best, but also the only thoroughly excellent manual, I know. The illustrations are admirable, well engraved, faithful to the actual appearances of the specimens, drawn by the ordinary magnifications of the microscope, and nearly all taken from the human subject. The text is singularly concise, clear and instructive, and exhibits familiarity with the most

recent investigations. With each figure are given categorical but sufficient directions for obtaining a duplicate specimen. In short, this little work has been prepared with great pains; it is unusually meritorious, and I take pleasure in giving it my hearty commendation:

#### RIPENING OF THE OVUM.

Within a few years we have gained much knowledge concerning the process of fertilization of the ovum. We may now look forward with considerable confidence to some real comprehension before long of the nature and essence of sexual reproduction. An important contribution has been made by Dr. O. Schultze, the talented son of that Max Schultze, whom every one places as the foremost microscopist of the world. Dr. Schultze has investigated the process of maturation of the ovum in amphibia.<sup>1</sup> It has long been known that in most ova two small bodies, called the polar globules are extruded from the surface of the yolk; the globules consist each of a portion of the nucleus of the egg, surrounded by a little of the yolk. Their general occurrence has led to the hypothesis that their extrusion is essential for the maturation of the ovum; but the hypothesis was rendered doubtful by the failure to find the globules in several classes of animals. Thus among vertebrates they had been found in fishes and mammals, but not in amphibia, reptiles or birds. O. Hertwig<sup>2</sup> hunted for polar globules in frog's eggs unsuccessfully. Schultze has, thanks to better methods and skilful observation, been more fortunate, and not only discovered the polar globules, but also observed other changes in the ripening egg-cell, which must be considered significant. Accepting his memoir as our guide, we may present the following account of the development of the amphibian egg.

The egg-cell enlarges and becomes surrounded by a follicular epithelium, and a thin membrane lying directly against the yolk. This membrane has been usually designated as the zona radiata. The nucleus steadily enlarges; in young ova it is central in position; spherical with a distinct membrane, an intranuclear reticulum, a number of chromatine granules (nucleoli) an abundant nuclear sap, etc. At one side appears a more or less nearly spherical accumulation of dark granules, constituting the mass known as the yolk nucleus, which was discovered by H. Cramer, many years ago.<sup>3</sup> The chromatine granules now arrange themselves around the periphery of the nucleus. The yolk nucleus breaks down and the granules composing it spread themselves out around the nucleus in a spherical layer, which lies about half way between the nucleus and the zona. The portion of the yolk between this layer and the nucleus appears much lighter than the yolk outside the layer. The ovum grows constantly, and the nucleus becomes enormous; the reticulum in it disappears and only the chromatine and the nuclear sap can be distinguished. The surface of the nucleus becomes quite irregular. After a time the division of the yolk into two zones is lost. The chromatine granules partly break up into small ones and before the ovum reaches its full size the granules acquire a characteristic and important distribution within the nucleus. There are still large granules around the periphery; and a cluster of them in

the centre, the large granules of the cluster form a shell around the kernel of small granules. The nucleus approaches the surface of the ovum; the granules of the little kernel in the centre of the nucleus unite into irregular threads; the membrane of the nucleus disappears, and the sap of the nucleus and most of the chromatine mingles with the yolk, but the tangle of threads remains and converts itself into a true spindle, but one of tiny size. Now, it has become well known by the researches of the past ten years, that these spindle figures are phases in the so-called indirect division of nuclei, and that nuclear spindles lying close to the surface of the ovum answers to one of the first stages in the development of the polar globules. In fact, there is here a polar globule of very small size produced. It is known that in the midst of the dark area of the freshly-laid ovum of the frog and other Anura, there appears a lighter spot, the cicatrula of Prevost and Dumas, the Keimpunkt of von Baer,<sup>4</sup> and named by Max Schultze<sup>5</sup> the *fovea germinativa*. This spot may occupy as much as a sixth of the whole surface of the ovum, but in some forms is much smaller; for example, *Bufo vulgaris*. In the midst of this white spot is a still purer white dot, in which again can be seen at least in axolotl eggs a still smaller black point, which was noticed and figured by van Bambeke in 1870, in his article "Sur les trous vitellins," etc.<sup>6</sup> This black point indicates the position of the nuclear spindle, it being due to a small gathering of pigment granules just about the spindle.

At first, the spindle has the peculiarity of lying with its long axis parallel with the surface of the ovum, but during the division of the spindle and the actual extrusion of the globule, the long axis places itself in a radial position. Subsequently, a second spindle is formed out of the part of the first left in the ovum, and a second polar globule is produced. The maturation of the ovum in amphibia, therefore, agrees perfectly with the maturation as it occurs in other classes of animals, at least, in all essential points. There is, in my mind, little doubt that polar globules of like history will be found in the eggs of reptiles and birds, when properly searched for. The significance of the polar globules for the theory of sex, I have pointed out on several occasions. For this reason, Schultze's discovery of the polar globules in a class of animals in which they had not been found before, is particularly important.

In the amphibian ovum, the history of the nucleus shows very clearly that a part of the nucleus only is concerned in the formation of the spindle, and that another part, in these animals, the larger part of the nucleus, mingles with substance of the yolk after the disappearance of the nuclear membrane. Schultze very properly directs attention to this curious phenomenon, which has hitherto attracted little notice, and adds the plausible suggestion that the mingling of the two parts may have a causal relation to the conversion of the indifferent egg-cell into the female ovum. The phenomenon is probably a constant one, but in other ova is less conspicuous than in those of the amphibia, because much less of the nucleus is employed in these animals to form the spindle than in any other known case.

When the first polar globule is formed the yolk begins to contract, and a little perivitelline fluid appears

around the yolk. After the formation of the second globule, the amount considerably increases; most of the fluid accumulates on top of the yolk, within the membrane of the so-called *zona*; the yolk under the fluid is flattened. This space above the yolk was called the "respiratory chamber" by Newport.<sup>7</sup>

In the arthropods, also, polar globules, which had long been sought for in vain, have now been found, both among crustacea and insects. As regards the former class, we have the observations of Grobben on *Moina*, and of Weismann<sup>8</sup> on the parthenogenetic ova of various Daphnida. Still more valuable are the observations of Blochmann<sup>9</sup> on various insects. This author found the eggs of *aphis aceris*, the plant-louse of the maple, a favorable object. The ova are short cylinders; the nucleus lies in the middle of the long side. In the winter eggs (which develop only when impregnated), after they have been laid, the nucleus changes into a nuclear spindle, which divides, after which one part, accompanied by a small amount of hyaline plasma, leaves the egg, so that a first polar globule is formed in the normal manner. The spindle-half left in the egg divides again, thus producing a second globule. In the summer eggs, which develop parthenogenetically, that is, without impregnation, there is a single globule, just as in the parthenogenetic ova of the Daphnida, studied by Weismann. Hence it is probable, as Blochmann points out, that since less matter is expelled in one case than in the other, the separation of the polar globules is of essential physiological importance as a preparation for fertilization.

Blochmann's observations greatly strengthen the hypothesis of parthenogenesis and sex which I published many years ago. According to this hypothesis, the cells include both male and female parts, and to make a female sexual product, the male part must be taken away; it was assumed that the polar globules represent this male portion. I further suggested<sup>10</sup> that, in parthenogenetic ova, the male element is not gotten rid of. Blochmann's observations indicate that it is gotten rid of, but only partially. In *musca*, the common fly, there are also two polar globules formed, of which the first subdivides, making three, as is the case in many ova; but there occurs here the remarkable peculiarity that the globules are not expelled, but melt together into a granular mass, which lies in a vacuolar space at the surface of the egg, and gradually breaks up. Blochmann<sup>11</sup> had previously found evidence of polar globules in ants, wasps, and a species of butterfly (*Pieris Brassicae*), so that these bodies have been found in four orders of insects.

In conclusion, we may put forward with great confidence the generalization that the formation of two polar globules is an indispensable part, and probably the essential part of the process of the maturation of the ovum throughout the animal kingdom from the sponges up.

#### ORIGIN OF THE WOLFFIAN DUCT.

As is well known, the duct, which persists in the adult male as the spermaduct, and in the adult female as a rudimentary structure, is a well-developed longitudinal tube on the dorsal wall of the abdomen of the young embryo, and serves as the excretory duct of the

primitive kidneys, or Wolffian bodies. Hensen, in his paper on the development of the guinea-pig and rabbit,<sup>12</sup> was the first to describe the origin of the duct from the ectoderm of the embryo. Graf Spee, in 1884, repeated and confirmed Hensen's observations, and added some admirable illustrations,<sup>13</sup> which recalled attention to the subject. Two years later, a second confirmation was given by Flemming, who investigated the rabbit.<sup>14</sup> Since then, the same fact has been found true of the thorn-back ray (*Raja clavata*) by J. W. van Wijhe, and in January of this year, Perenyi published a note in the *Zoologischen Anzeiger* to maintain the same mode of origin for the Wolffian duct in frogs and lizards.

We may, therefore, conclude that the canal arises in this manner in all vertebrates. The theoretical bearings of this are very noteworthy. It appears that the primitive excretory apparatus was originally a series of coiled, transverse tubules, opening at one end into the abdomen, at the other into the Wolffian duct. An admirable treatment of the history of the excretory organs of vertebrates, by Balfour, may be found in the second volume of his "Comparative Embryology." Now these tubes bear an obvious likeness to excretory organs of annelids, termed the segmental organs. The resemblance has been generally considered an argument in favor of assuming a common ancestry for worms and vertebrates, or, more strictly speaking, in favor of homologizing the excretory organs of one class with those of the other. There was, however, one serious difficulty in the way of this conclusion, to wit, the tubules in annelids open upon the exterior surface of the body, but those in vertebrates open upon the interior into a longitudinal canal. Formerly, there was no way of explaining the divergence; but Hensen's observation, extended as it has been, reveals a mode of origin of the Wolffian duct, which proves that it really belongs to the exterior, being derived from the ectoderm. Hence organs which open into the Wolffian duct open, morphologically speaking, upon the exterior of the body. Therefore, there is no longer any obstacle to prevent our maintaining a direct homology between the tubules of the Wolffian body and the segmental organs of worms.

Shortly after I had finished the manuscript of the preceding paragraph, I received through the kindness of the author, Prof. A. C. Haddon, a reprint of a paper read to the Royal Dublin Society on February 16th last, in which the theoretical meaning of the ectodermal origin of the duct is discussed excellently. Haddon says in reference to the hypothetical ancestors of vertebrates, "we have only to assume that the lateral area along which they (the transverse or segmental tubules) opened, was grooved, and extended as far as the anus. From the analogy of the neutral groove, there is no great difficulty in further supposing that the groove was converted into a canal, which, becoming separated from the overlying epiblast, might sink into deeper-lying parts of the body;" (p. 469).

#### PLACENTA AND UTERUS.

Two large atlases with plates of sections through the body of pregnant women, have appeared during the year. Both atlases are based upon frozen sections. One, issued by Prof. Waldeyer, gives the relations as found in a normal pregnancy assigned to the eighth

month, the other, edited by Dr. Karl Schroeder, illustrates the dispositions in labor during "*Eröffnungsperiode*." Both works include a valuable text, Schroeder's, including several articles by Hofmeier, Ruge and Stratz. Hofmeier's article is of little value, at least in proportion to its length, but Ruge's is meritorious, and contains better accounts of many features of the pregnant uterus than can be had elsewhere. I have pointed out<sup>12</sup> that a part of Ruge's views cannot be sustained because he was unaware that the layer of fetal epithelium covering the chorion and chorionic villi persists intact through the entire period of pregnancy, although it undergoes remarkable alterations, becomes irregularly thickened, and in the thickened parts undergoes a hyaline degeneration, which produces the canalized fibrine, first accurately described as a normal placental structure by Langhans. A knowledge of the singular history of the chorionic epithelium is important alike for the comprehension of the normal structure of the placenta, and for the elucidation of the pathological changes to which this organ is subject.

Fleischman enters the lists as a defendant of the old view that the chorionic villi lodge in the uterine glands. He maintains that in the fox and cat the glands enlarge and develop irregular diverticula, the septa between them become very small; the villi grow into the glands; the uterine epithelium disappears, first on the surface and there entirely, secondly, in the glands, partially in the cat, completely in the fox. The chorionic epithelium is preserved in both species. This is a return to Bischoff's opinion. Turner asserted that the crypts into which the villi grew, were new formations. Ercolani denied that the villi grew into either glands or crypts.

Colucci<sup>13</sup> in reply to an article by Laulanie,<sup>14</sup> defends Ercolani's conclusion that the maternal portion of the placenta preserves a glandular character in all cases, and furnishes a secretion to nourish the fetus. A summary of Ercolani's views on the placenta is given by Romiti, in his *Embriogenia umana e comparata* and also in Paladino's *Fisiologia*. It seems to me now, however, that Ercolani was in error in considering that his generalization can be applied to all placenta. It does not appear to hold for the human placenta, at least during the latter part of pregnancy. Concerning the precise structure of the human placenta, during the first months of gestation, we possess no satisfactory observations.

The conflicting views have been carefully considered by Tafani in a long memoir<sup>15</sup> in which he reports many new observations. I regret very much that the work has been at hand too short a time for me to have completed the perusal of it in time for this report.

The most important paper on the human placenta, which has appeared since Langhans' memoir<sup>16</sup> in 1877, is in my estimation the very brief article of Prof. Waldeyer, which is crammed with valuable information. By most scrupulously careful injections, he has ascertained that the intervillous spaces are actually channels of the maternal circulation. The veins and arteries as they enter the decidua seratina lose completely all their coats except the endothelial lining. They pass up with this modification of structure through the decidua, giving off very few branches, and finally

open directly upon the decidua surface into the intervillous spaces. Waldeyer leaves it in doubt whether there is any maternal tissue (that is, endothelium) covering the fetal epithelium of the villi, but is inclined to think such a layer is present. I have looked for it again in my own preparations, but cannot discover any trace of it. On the other hand, I have been so fortunate as to obtain some sections which confirm Waldeyer's description of the opening and histological peculiarity of the decidua veins. The original paper is from the *Sitzungsberichte* of the Berlin Academy for 1887.

## Reports of Societies.

### PHILADELPHIA COUNTY MEDICAL SOCIETY.

STATED meeting, May 11, 1887, the Vice-President, E. T. BRUEN, M.D., in the chair.

DR. THOMAS B. MCBRIDE described and exhibited A NEW APPARATUS FOR MAINTAINING THE LITHOTOMY POSITION.

I desire to present to the Society, this evening, an apparatus I have designed for the purpose of supporting the limbs and maintaining the lithotomy position.

It consists of a piece of hard, elastic wood, preferably ash or hickory,  $\frac{3}{8}$  of an inch thick, 1 inch wide, 36 inches long, bent at each end in a semicircle of 6 inches diameter, or a semicircumference of 10½ inches, thus leaving a shaft of 15 inches between the semicircles, and making the finished length of the instrument 27 inches (6 + 15 + 6).

To the shaft, 2 inches from each end, a buckle is immovably fastened by means of leather.

A band of webbing, finished at each extremity with a leather strap, the whole 50 inches long, completes the device.

In using the apparatus, the thighs are flexed on the abdomen and put in the semicircles, the band is placed around the neck and fastened to the buckles.

The advantages are apparent. Its cheapness places

<sup>12</sup> Anatomischer Anzeiger, Vol. II, No. 1.

<sup>13</sup> Mem. Acad. Bologna Ser. IV, Vol. vii.

<sup>14</sup> Revue Vet. Xme Année, No. 3, Toulouse, 1883.

it within the reach of every one. The thoroughness with which it does its work, keeping the patient immovably in the lithotomy position, and maintaining the same relative position of the parts; the fact that it does not interfere with the circulation; the strength, lightness, and remarkable simplicity will, I think, render it a valuable acquisition to the surgeon and gynecologist.

#### AMERICAN SURGICAL ASSOCIATION.<sup>1</sup>

ANNUAL SESSION OF 1887.

REPORT OF A CASE OF VENTRAL HERNIA SUCCESSFULLY TREATED BY OPERATION, WITH A SUGGESTION AS TO THE METHOD OF OPERATING,

by DR. J. EDWIN MICHAL, of Baltimore.

Mrs. F., stout woman, forty-five years of age, had ventral hernia, resulting from a fall several years previously. Great annoyance was experienced in the use of pads and bandages. The longitudinal opening was about two and one-half inches in length. The patient insisted on operation. March 15, 1886, the operation was performed. Antiseptic precautions were adopted. Free incision was made in the median line. The sac was carefully separated from surrounding tissues; it was then emptied of its contents and opened. The sac was cut off close to the margin of the ring. Strong silver-wire sutures were passed a little less than one-half an inch apart, having a hold of one-half to three-fourths inch. The sutures included the peritoneal, muscular and tendinous structure only. These were twisted and perforated shot employed. The wire was then cut off close. The skin and subcutaneous tissues were secured with cat-gut sutures. Half-dozen cat-gut strands were placed in the wound for drainage. The wound united rapidly. In October examination of the wound showed it to be firmly united. The sutures could be felt but gave no inconvenience. In his remarks the speaker stated that his object in using the wire sutures in this manner was the expectation that they would be surrounded by a mass of cicatricial tissue making a permanent closure of the ring. As far as he was aware he had used the wire for this purpose without precedent. A paper on

#### PROGNOSIS IN SARCOMATA OF THE BREAST,

by S. W. GROSS, of Philadelphia, was read by title, and referred to the publication committee.

#### THE MEDICO-LEGAL ASPECT OF CRANIAL AND THORACIC WOUNDS [SUICIDAL].

by DR. D. HAYS AGNEW, of Philadelphia.

The study of this subject had been suggested to him by a recent case occurring in Newport, R. I. The question was as to the possibility of a cranial wound and a wound of the heart being self-inflicted. A colored man was found one morning lying dead under the breakfast table. He had food in his mouth and had a wound of the head and of the heart. The coroner's jury rendered a verdict of suicide and the body was buried. Subsequently it was disinterred and the verdict reconsidered, and the conclusion reached that the man had been murdered. Suspicion then fell upon the son-in-law of the man, who had up to this time borne a good reputation. At the trial five medical experts were called for the prosecution, and their

general testimony was that these wounds were incompatible with the idea of suicide. Subsequently the prisoner confessed that he had committed the murder. As this was an important question the author had investigated it. There are two conditions resulting from injury of the head which would prevent the infliction of a second injury. These are unconsciousness and paralysis of one or both upper extremities. Injury to the brain is not necessarily followed by loss of consciousness or by paralysis. Many cases were cited to show the truth of this statement. Numerous instances of heart injury were given in which after the reception of the accident the individual was able to perform many acts. Cases were also given in which persons in attempting suicide had produced injuries of the head and of the heart. As the result of his study, the speaker concluded that it is possible for a ball to enter the brain without destroying consciousness although for a moment it may cause mental confusion, and that a suicide may shoot himself in the head and after a moment shoot himself in the heart.

In the discussion which followed, numerous cases were related in which the heart or brain had been injured and the individual had lived for some time and had not been unconscious. Cases were also given in which both a wound of the heart and of the brain had undoubtedly been produced by the individual himself.

Adjourned until Friday morning.

FRIDAY, MAY 13. MORNING SESSION.

#### EXECUTIVE SESSION.

Officers for the ensuing year: *President*, Dr. D. Hayes Agnew, of Philadelphia. *Vice-President*, Dr. N. Senn, of Milwaukee, and Dr. F. S. Dennis, of New York. *Secretary*, Dr. Jacob R. Weist, of Richmond, Indiana. *Treasurer*, Dr. Phineas S. Conner, of Cincinnati, Ohio. *Recorder*, Dr. J. Ewing Mears, of Philadelphia, Pa. *Council*, Drs. J. S. Billings, L. McLane Tiffany, Moses Gunn, and R. A. Kinloch. *Chairman of Committee of Arrangements*, Dr. John S. Billings, of Washington. The following were elected to membership: Charles B. Porter, M.D., of Boston; William M. Masten, M.D., of Mobile, Ala.; and Maurice H. Richardson, M.D., of Boston, Mass.

The next meeting to be held at the call of the President.

#### SURGICAL DISEASES OF THE WHITE AND COLORED RACES COMPARED,

by L. McLANE TIFFANY, of Baltimore.

The paper was based on the record of 4,930 cases, studied during a period of thirty-four months in a general hospital. The percentages of the affections were given in detail. The paper was simply intended as a preliminary communication, and as a result of a study of the figures obtained, the following suggestions were made:

(1) Surgical affections follow different courses in the white and colored races, under identical hygienic surroundings.

(2) Surgical injuries and operations are better borne by negroes than by whites.

(3) Surgical diseases involving the lymphatic system, especially tubercular, are more fatal and more rapidly fatal in negroes than in whites.

(4) Congenital deformities are rarer in negroes than in whites.

<sup>1</sup> Continued from page 509.

(5) The surgical differences observed in whites and negroes are due to racial peculiarities.

## DISCUSSION.

DR. CHRISTOPHER JOHNSTON, of Baltimore. My experience indicates that there are individual as well as racial peculiarities. These are most striking in proportion to the pureness of blood. I regard the negro as a good subject for surgical operation. I have never seen carbuncle in negro. I do not recall a cleft palate or hare lip in the darker individuals. Epithelioma is infrequent. Fibromas are quite frequent. I would emphasize the proneness to the development of keloid in the negro. I have found that in the negro, the skin and white tissues are more frequently the seat of certain disease than the same tissues in the white.

DR. P. H. RICHARDSON, of New Orleans, presented a detailed report of the statistics of the Charity Hospital, bearing upon this point. He had found congenital deformities rarely in the negro.

DR. E. H. GREGORY, of St. Louis. I have seen keloid much more frequently in a negro than white, and have never seen multiple keloid in the white race. The ability of negroes to stand operations may be due to his indifference, and that he does not comprehend the magnitude of the operation. The results obtained at the City Hospital of St. Louis, show that the negroes bear operations about as well as whites. It seems to be the generally accepted idea that negroes are more subject to tubercular affections.

DR. W. T. BRIGGS, of Nashville, Tenn. My experience confirms the suggestions of Dr. Tiffany. Negroes are very prone to suppuration. It is extremely difficult to prevent suppuration even under strict antiseptic precautions. Negroes bear operations better than whites, but they do not get well so rapidly. While malformations are less frequent, still they do occur. The rarity of hydrocele in the hospital records may be explained by the fact that negroes do not usually seek advice until the tumor has become so large as to give rise to much inconvenience. Fibroids and fibro-cystoma are very common in the negro. Ovarian tumor is rare, although I have had one case in which the tumor weighed one hundred pounds.

DR. D. W. YANDELL, of Louisville, Ky. I agree with Dr. Briggs in his remarks. I have seen many cases of keloid in the negro, but have not seen a case in the white subject. I have seen but two cases of hydrocele in the negro. I never saw hare-lip in the negro. I have seen but two ovarian tumors in the negro. I never saw epithelioma of the face of a negro. Epilepsy is exceedingly rare in the negro. I never saw a case of internal hemorrhoids in the negro. Tetanus is exceedingly common, especially in the black race. Stricture of urethra is exceedingly common among negroes.

DR. R. A. KINLOCK, of Charleston, S. C. In considering this subject I think we make a mistake in classing all negroes together. I think that in the pure negro suppuration is less likely to occur than in the white race. As a rule I think that the negro is not strumous. Mulattoes are, as a rule, strumous. The pure negro bears operation well, and recovers promptly.

DR. A. VANDER VEER, of Albany. During the past twenty years I have seen a good many negroes, United States prisoners sent to the Albany penitentiary. The vast majority of these die of tuberculosis

of some form. Many of them have soft chancre with suppurative buboes. Where there is true Hunterian chancre, there has been the characteristic bullet bubo seen in the white race. There are a greater number of perineal abscesses and sinuses than in the white. If operation is done there is less probability of urethral fever.

## AN EXPERIMENTAL STUDY OF THE EFFECTS OF PUNCTURE OF THE HEART IN CASES OF CHLOROFORM NARCOSIS,

by B. A. WATSON, M.D., of Jersey City, N.J. The investigation of this subject was suggested to him by the following occurrence: February 20, 1887, he had killed with chloroform a dog. The abdominal and thoracic cavities were opened, about four minutes after the heart had ceased to beat. The assistant seized the heart with his thumb and forefinger and the pulsations at once began, the contractions became full and regular, and continued three minutes. They were again stimulated by a second touch, action continuing two minutes. They were started a third time and continued to beat one-half minute. This observation suggested the possibility of arousing the heart into action even after entire cessation of its movements, by the introduction of a needle into the organ.

The results of sixty experiments on dogs were given in detail. The experiment consisted briefly in producing death by chloroform inhalation, and then withdrawing from one to three or four minutes an aspirating needle was introduced into the heart through the chest walls, the attempt being to reach the right ventricle. In the first fifty cases the chloroform was administered rapidly and air was excluded as far as was possible. In the last ten the chloroform was administered slowly and with a large proportion of air. The first forty animals had already suffered some severe traumatic injury, while the last twenty were perfectly healthy animals. The punctures made in these sixty experiments were as follows: right ventricle 38; left ventricle 6; right auricle 6; superior vena cava 3; inferior vena cava 2; apex of the heart 2; and not stated 1. The resuscitations were as follows: after puncture of the right ventricle nine; right auricle one. The first forty experiments gave only four recoveries, while the last twenty gave six. In only one of the sixty cases did the heart fail to respond to puncture, and in this instance the use of the needle was postponed for four minutes after the cessation of the heart's action and one minute after breathing had stopped.

Should the puncture be carried into one of the cavities of the heart in order that blood may be extracted? In chloroform narcosis the heart is found in diastole and the veins in the lungs are greatly distended with blood. It may, therefore, theoretically be assumed that blood may be advantageously drawn from the right side of the heart. The author was assured that this procedure was practical and advantageous.

The only deaths during these experiments which could be attributed directly to the puncture were those in which the needle penetrated the vena cava. In these cases there was profuse hemorrhage into the thoracic cavity. Punctures made into the auricle are sometimes followed by a flow of blood into the pericardium. Punctures into the ventricle are not attended with any hemorrhage from the interior of the organ, but there may be a few drops of blood from a wounded cardiac vein.

The following conclusions were reached:

*First.* Puncture of the heart, especially of the right ventricle, stimulates muscular contractions, and may be advantageously applied in the treatment of chloroform narcosis.

*Secondly.* The best results are obtained when abstraction of blood from the cavity of the ventricle is combined with the stimulating effects produced by the entrance of aspirator needle.

*Thirdly.* The puncture of the right ventricle is a safer and more efficient operative procedure than the puncture of the right auricle.

#### DISCUSSION.

DR. N. P. DANDRIDGE, of Cincinnati. We should, I think, be careful how we apply the deductions from these experiments to the human being. The conditions under which the experiments were made were different from those under which accidents usually occur in human beings. In the latter case the accident usually occurs after only a small quantity has been taken and often early in its administration. The effect is probably due to a reflex effect upon the inhibitory action of the heart. In the experiments reported puncture was resorted to within one or two minutes after the cessation of the heart's action. In the accidents with chloroform it is not uncommon to have recovery after apparent cessation of the heart's action for a comparatively long period. A large number of experiments are required to test the relative value of this procedure as compared with artificial respiration, the use of nitrite of amyl and particularly with the subcutaneous injection of atropia. This latter can always be done quickly, and has a stimulating effect upon the cardiac and respiratory centres.

DR. JOHN B. ROBERTS, of Philadelphia. The speaker, while he has shown the comparative innocuousness of puncture of the heart with a small needle has also shown the danger of using chloroform as an anæsthetic in any cases, possibly cases of parturition excepted. I doubt whether he could have killed the same number of dogs with ether. His experiments have shown that it is more dangerous to puncture the auricle than the ventricle, which would naturally be suggested by the fact that the auricle has a much thinner wall. Dr. Westbrook, who performed cardiotomy for conditions other than chloroform narcosis, suggested puncture of the right auricle to the right of the sternum. I suggested in 1883, that it would be better to puncture the right ventricle to the left of the sternum.

DR. L. McLANE TIFFANY, of Baltimore. There are two points in which these experiments are open to criticism. It is well known that on dogs, chloroform acts in a very uncertain manner. It is not safe to make deductions from the dog to the human being, under these circumstances. In the second place, I think it is not well to make experiments in the laboratory, and then advise others to try them on the human subject. The experimenter should test the experiments on the human subject, before he recommends the procedure to others.

DR. R. A. KINLOCH, of Charleston. In a recent case of chloroform narcosis in my practice, heart puncture was tried, but without the slightest benefit.

DR. T. J. DUNOTT, of Harrisburg. I know of one case in which the heart was twice punctured with an aspirator needle, and blood drawn from the cavity of

the heart. It was a case of dilatation of the heart with general dropsy, etc. The operation was performed by a homœopathic practitioner under the idea that he was dealing with a case of dropsy of the pericardium. A large quantity of blood was removed, and for a time there was improvement. The symptoms again returned and the operation was repeated, with a fatal result.

DR. B. A. WATSON, of Jersey City. Reference to the details of these experiments will show that in some the heart was excited to action fully three minutes after it has ceased. There are two reasons for selecting the right ventricle in place of the right auricle. In the first place, its walls are thicker, and the risk of hæmorrhage is less. In the second place, there is much more muscular substance in the wall of the ventricle than in the auricle.

With reference to the action of chloroform on the dog, I am well aware of the uncertainty of its action, but this is all against the dog. Where I have attempted to continue the anæsthetic action of chloroform on dogs for two hours, I lost one-half of the animals.

The committee to which was referred the suggestions contained in the President's address, reported that in view of the satisfactory manner in which the work of the present meeting had been prepared, it saw no reason for a change, and did not recommend the appointment of a business committee. It recommended the adoption of the second suggestion with reference to the length of papers. With reference to the abrogation of Article 9 of the Constitution, the committee was in accord with the president, but as this article had been introduced at the express desire of the first President of the Association, it was recommended that it be allowed to remain. The committee recommended the adoption of the suggestion that applications for membership lay over for one year.

#### FRIDAY.—AFTERNOON SESSION.

#### HYPERTROPHY OF THE TONGUE, OTHERWISE KNOWN AS LINGUA VITULI, LINGUA PROFUNDULA, AND MACROGLOSSIA,

by T. J. DUNOTT, M.D., of Harrisburg.

This affection of the tongue, although rare, is mentioned by nearly all surgeons of large experience. The case described by the speaker was that of a girl, twelve years of age, admitted to the Harrisburg Hospital, January 6, 1886. The tongue protruded from the mouth a distance of three and five-eighths inches. The lips were greatly distended, and the angles of the mouth not far removed from the external opening of the auditory canal. The greatest width of the tongue was four and three-quarters inches, and the greatest circumference nine and three-quarters inches. The prolapse of the tongue was only of two months' duration, and had begun without apparent cause. The measurements taken one week after admission showed a decided increase in the size of the tongue. The tongue was removed February 19th. After providing against hæmorrhage, the organ was removed with scalpel and scissors, the section being so made as to secure a conical stump. All the dense fibroid mass was taken away, the weight of the removed portion being over ten ounces. By January 31st, the stump was easily healed. There was no difficulty in keeping the mouth closed. When heard from, March 28d, she could eat and drink without difficulty, and was

gaining flesh rapidly. The paper was concluded with an account of the various operations which had been practised for the removal of the tongue.

## DISCUSSION.

DR. L. McLANE TIFFANY, of Baltimore. The history of the case just given would well apply to a case which I have recently seen. A negro girl, five years of age, had suffered with hypertrophy of the tongue, dating from birth. Ever since the first few months of life, the child had been unable to cover the tongue with its lips. The tongue was removed with the Paquelin cautery. Within a week the patient was eating potatoes and meat, and left the hospital ten days after operation. At this time there was a healthy granulating surface.

## CASES OF VAGINAL HYSTERECTOMY.

by J. FORD THOMPSON, M.D., of Washington.

CASE I. Mrs. A. E., aged forty-five years, white, was seen in April, 1885, suffering with malignant disease of the uterus. There was great destruction of the cervix, the ulceration extending above the internal os. On consultation, it was decided to avoid hysterectomy if possible, but to limit the operation to amputation of the cervix with scraping, etc. During the operation, the peritoneal cavity was opened. It was then decided to extirpate the uterus. The womb was separated from the bladder in front. A ligature was then placed around each broad ligament and tied. The uterus was then split in two. Each half was then brought down the broad ligaments, tied above the temporary ligatures, and the uterus removed. After thorough cleansing, the vagina was lightly packed with iodoform gauze. At the end of the operation the patient was very weak, and notwithstanding all efforts died in the course of twenty-four hours.

CASE II. Mrs. H., white, aged fifty-five years. Came under observation with cancer of the cervix in January, 1887. The posterior lip of the cervix was almost entirely destroyed, and the disease had encroached upon the posterior cul-de-sac. The cervical canal was involved, at least as high as the internal os. The operation was performed February 28, 1887, antiseptic precautions being adopted throughout. The dissection was begun at the posterior part and carried around the cervix. A silk ligature was passed with a long curved needle through the lateral vaginal vault of either side, and tied. The inclosed portion was then cut from the uterus. These ligatures presumably enclosed the uterine arteries and the lower part of the broad ligament. The uterus was then separated from the bladder in front, and a loop of silk was attached to the peritoneum. The posterior cul-de-sac was treated in the same way. The uterus was then tilted through the opening, and the broad ligaments transfixed and tied. There was no loss of blood. The peritoneal flaps were then brought together with two cat-gut sutures and a drainage-tube introduced into each angle of the wound. The vagina was packed with iodoform gauze. The patient recovered without any unpleasant symptoms.

Reference was then made to the history of the operation and the various methods of performing it were described.

## DISCUSSION.

DR. T. R. VARICK, of Jersey City. Whether such operations as this are likely to mitigate suffering

or prolong life beyond the average duration of the disease, if left to take its course without interference, is a question to be yet determined. It seems to me that any operation or method of treatment whose record does not show a prolongation of life beyond the utmost limit of the duration of the disease, if left to itself, is useless and should be avoided.

DR. T. F. PREWITT. I thoroughly agree with the author that extirpation of the uterus is a justifiable operation, and I do not know but that I am prepared to go further and say that on the earliest appearances of epithelioma of the cervix, the whole organ should be extirpated. I believe that ultimately this will be the course adopted.

DR. E. A. GREGORY, of St. Louis. It is one of the rules of old surgery to save every part possible, and I should no more think of removing the entire uterus for epithelioma of the cervix, than I should think of removing the whole lip for limited epithelioma of that part. I think that the surgery of the lips and the surgery of the jaws is applicable to the uterus. I am not willing to sit here and have the old ideas of surgery assailed without some show of resistance.

DR. R. A. KINLOCH, of Charleston. Another of the rules of old surgery was that in malignant disease, we should cut far and wide. The older surgeons, as well as the modern, recognized the fact that malignant disease often spreads too rapidly for us. Here we have an organ suspended in the pelvis and easily isolated. Now, if statistics show that by cutting far and wide without jeopardizing life too much, we can cut short the disease, we are carrying out the rules of old surgery when we do so.

## ANEURISM OF THE LEFT SUBCLAVIAN ARTERY FOR THE CURE OF WHICH THREE METHODS OF TREATMENT WERE EMPLOYED. DEATH.

by T. G. RICHARDSON, M.D. of New Orleans.

The patient, a healthy muscular Irish laborer, came under observation October 19, 1885. Aneurism of the left subclavian artery was diagnosed. The patient had suffered with syphilis, and constitutional measures were first tried. Iodide of potassium in fifteen or twenty grain doses was given three times a day. At the end of a week, no perceptible effect being observed, it was discontinued. Direct pressure was next tried, an elastic band with a compress over the vessel was secured to a belt around the waist. This was continued a month, and although it slightly retarded the growth of the swelling, it had no decided result. The third method, the introduction of surgical pins was next resorted to. Nineteen of these, measuring an inch-and-a-half in length, were passed through the anterior wall of the tumor at different places. The aneurism was still growing rapidly, and all the pins that could be reached were then withdrawn. Some of them had disappeared on account of the swelling which had taken place. An attempt was then made to ligate the axillary artery, but in spite of the utmost care, the lower portion of the aneurism was ruptured in the progress of the operation. The wound was at once packed with lint, dipped in Monsel's solution. The hemorrhage having been stopped, half a drachm of a five per cent. solution of perchloride of iron was injected into the centre of the tumor. At the end of twenty-four hours no coagulation having taken place, a second injection of twice the strength was employed.

The next morning there was an exhausting hæmorrhage ending fatally in a few hours.

**FEMORAL ANEURISM CURED BY ELEVATION AND FLEXION OF THE LIMB,**

by Dr. T. G. RICHARDSON, of New Orleans.

The patient, an Italian, aged fifty-five years, was admitted to the hospital December 11, 1886, with a large aneurism of the femoral artery four inches below the femoral arch. While the case was being studied, the limb was flexed at a right angle at the hip and knee, and suspended on a Smith's anterior splint. The next day the pulsation was greatly reduced and the patient was quite comfortable. The treatment was continued, and at the end of the third day the tumor was solid. The limb was kept in this position for ten days or two weeks. The patient was discharged cured, one week later. The speaker called attention to the fact that there was no direct pressure upon the tumor, and that the result was due entirely to flexion and suspension of the limb.

**WOUNDS THEIR ASEPTIC AND ANTISEPTIC TREATMENT**

by DAVID PRINCE, M.D., of Sacksonville, Ill.

After referring in general terms to the methods in use for the prevention of contamination of wounds, the speaker described an operating-room which he had devised, the object of which was to prevent the entrance of infecting principles. All the air entering this room is filtered through successive layers of cotton. The air is heated by means of gas-burners and to prevent drying of the wound. Steam is permitted to enter with the air.

**SPLENECTOMY,**

by JAMES McCANN, M.D., of Pittsburg.

The paper was the description of a case in which removal of the spleen had been practised, with recovery of the patient. A paper entitled

**THE STUDY OF THE METHODS OF OPERATION PRACTISED, AND OF THE RESULTS OBTAINED IN THE TREATMENT OF CLEFT OF THE HARD AND SOFT PALATES, ILLUSTRATED BY THE RECORD OF FIFTY CASES.**

by J. EWING MEARS, M.D., of Philadelphia, was read by title.

A vote of thanks was then extended to the Surgeon-General for the use of the room; to the Cosmos Club for courtesies extended, and to the officers of the Association for the efficient manner in which the proceedings had been conducted.

The Association then adjourned to meet at the call of the president.

—Mr. O'Brien, a Liverpool surgeon, says in a recent issue of the *British Medical Journal*, that for a few weeks he has had under his care a little boy suffering from an unusually severe attack of whooping-cough, and that the boy's mother informs him that for as much as a fortnight the family cat has had five or six distinct fits of coughing daily, similar in every respect to the boy's, and ending in an expectoration of frothy mucus. The cat is said to be tolerably bright and active between the paroxysms, but is not so lively as formerly, and is in considerably poorer condition.

**THE NEW YORK ACADEMY OF MEDICINE.**

STATED meeting, April 21, 1887.

**DISCUSSION ON THE PRACTICAL VALUE OF OUR PRESENT METHODS OF TREATING THE UPPER AIR-PASSAGES.**

This subject was presented for discussion by the Section on Laryngology, and the first paper was read by Dr. F. H. Bosworth. When the specialists in this department knew very little, he said, they made use of a great deal of machinery; but as they came to know more, the array of machinery had grown less and less imposing, until now all the apparatus that was really necessary, might be readily carried in the overcoat pocket. Notwithstanding the most ingenious devices for their employment, it was a fact, that no case of chronic laryngitis had ever yet been cured by topical applications. The views of laryngologists had greatly changed within the last few years, and they had long since outgrown the idea that chronic laryngitis must be of either tubercular or syphilitic origin. The truth was, that non-specific chronic laryngitis was merely secondary to affections of the parts above.

As to applications to the lower pharynx, they were of no service whatever, and this part of the anatomy did not even belong to the air-passages at all, but to the food-tract. The vault of the pharynx was the seat of certain morbid changes which had been supposed to constitute naso-pharyngeal catarrh. The excessive secretion which was fancied to be characteristic of the condition, however, was an absolute myth. There was, in fact, diminished secretion, (although the secretion was perverted, so that it became thick and inspissated to a degree that it was not removed by the ordinary efforts at expectoration), and the indication was, not for astringent applications to the pharynx, but for some means of treatment which would restore the nasal passages as far as possible to their normal condition. Topical treatment here, therefore, was no use, and in such conditions as hypertrophy of the pharyngeal tonsil, no local measure was of any service, except merely as a palliative. As to nasal catarrh, it was not a hyper-secretion to be cured by astringents. These had all been tried to the fullest extent, and found to be of no avail. The essential symptoms were due to conditions which interfered with the great function of exosmosis of serum, and douches and sprays had never yet cured inflammatory conditions of the upper air-passages, although such applications were undoubtedly of more or less use. The nasal douche had attracted a great deal of attention of late years, and he thought its dangers, as well as its benefits, had been vastly over-estimated. Inhalations had fallen into disuse, and the spray was now deservedly considered the most satisfactory means of local treatment. It was unquestionably of great assistance as a cleansing and palliative measure; but was nothing more than this.

As to any special value to be attached to any particular form of apparatus, there was none. Compressed air was supposed to possess superior advantages for the spray, and the moral effect of the various devices resorted to for employing agency was no doubt good; but with an instrument costing a dollar-and-a-half at retail, as perfect a spray could be produced as with the most elaborate machinery. Millard's atomizer, he thought, was the one which was most convenient and

serviceable. The curative treatment of affections of the upper air-passages, however, consisted in treatment of the nasal tract by the removal of obstructive lesions which gave rise to nasal stenosis; and this was to be carried out with the snare, saw, knife or cautery.

The object sought to be secured by the use of the cautery, was not destruction of tissue. In hypertrophic disease the process involved principally the connective tissue, and the essential feature of chronic rhinitis was a chronic hyperæmia of the bloodvessels, with increased nutrition of the part. The local effect of cocaine was to produce anemia, and, having reduced the existing turgescence with this agent, a mild caustic which would have very much the action of a film of collodion, should be applied. There was nothing so good for this purpose, in Dr. Bosworth's opinion, as chromic acid; a few crystals of which, laid upon the parts, destroyed the superficial layer of the membrane, converting it into a slough which adhered closely to the surface for three or four days; holding it down, as it were, and preventing a return of the turgescence. This simple method by chromic acid was greatly to be preferred to the galvano-cautery, enabling us to accomplish, as it did, all that could be effected with this complicated apparatus, in a manner much more satisfactory in every way. The subject of neoplasms, he said, did not properly come under the present topic of discussion. Acute catarrhal inflammation of the nasal passages was simply a symptom of chronic rhinitis, and as it could be readily eliminated by means of cocaine, did not require further consideration.

In speaking of our methods of examination, he said that the value of the laryngoscope, as generally employed, was greatly over-estimated, and that neither in Tobold's or Sass's instrument was there any optical principle involved. A small head-mirror, with a good light, answered every purpose perfectly well. Laryngologists had ceased to treat by means of machinery when they learned how to successfully treat their cases; and he quite agreed with the sentiment expressed by Dr. Daly at the Copenhagen International Medical Congress, that the sooner they ceased to be throat doctors and became throat surgeons, the sooner would they achieve success in their specialty.

Dr. A. H. SMITH while expressing his belief in the efficacy of topical application in many more or less acute conditions, said that in long established cases of what is known as catarrh, there were serious doubts in his mind as to the benefit of any local treatment that had as yet been devised. In one of the institutions in New York where such cases are treated, there were, during the year 1886, 1,773 patients suffering from chronic nasal catarrh, and in these 1,773 cases, 370 operations were performed, or in a little more than 27 per cent. of the number. About 73 per cent., therefore, were treated by topical means, exclusive of surgical procedures. Hence, it seemed that in nearly three-quarters of all such cases we had to depend on topical applications. But as it was notorious how rebellious to treatment other chronic affections of the mucous membrane, such as conjunctivitis, otorrhea and endo-metritis, were, it was fair to infer that in chronic rhinitis, where it was impossible to reach all the parts affected, as in the others, the results would not be any more satisfactory. Under the most favorable conditions, all we could do, he thought, was to assist the reparatory processes of nature.

It was a question, however, whether in chronic cases the *vis medicatrix nature* was not entirely obliterated. In many instances it really seemed that the natural tendency was to a still wider departure from the normal condition. It was a sheer assumption to suppose that local application would have the desired effect. Not only was a large amount of the nasal mucous membrane in positions inaccessible to local treatment by vapor sprays and powders, but the diseases located in this region were due to causes which had long been operative; and it was of little use to heal a burn while the hand was still in the fire. These remarks, he said, were not applicable to all troubles in the upper air-passages, but to certain chronic affections; and it was only just to ourselves and frank to the public that the professional sentiment in this matter should be made known. Personally, he had long ceased to expect, as he had long ceased to promise, a complete and permanent cure in such cases. As to acute exacerbations, however, they could be successfully treated with anodynes and astringents.

Dr. W. H. THOMPSON said that in his opinion the treatment of chronic disease of the upper air-passages should be directed by two principles. The first of these was the taking cognizance of the cutaneous nerves liable to be concerned in the trouble, and the second, local disinfection. While in some affections, as, for instance, pertussis, infectious germs were taken into the system from the air breathed; in others the origin seemed to be in a quite local chill of the cutaneous surface. The whole body might be exposed in the rain and yet the individual not be nearly so likely to take cold as if he got only his feet wet. In the same way a draught through the key-hole was very liable to give cold.

There were three laws of neuro-vascular irritation which should be taken into consideration in this connection: In the first place, organs in symmetrical pairs were so closely associated in their vaso-motor relations, that an influence affecting one was at once conveyed to the other also. Thus, Brown Squard had shown that the thermometer indicated a fall of fourteen degrees in one hand from the dipping of the other in ice-water, while, in the axilla, the temperature remained unaffected. The second law had reference to the association of the vaso-motor influences of various organs with the surface. Thus, a dash of ether-spray was often efficient in checking hæmoptysis, and the action of all derivatives and counter-irritants depended on this connection. The third law was concerned with the cerebro-spinal vaso-motor connections. The relations between the pelvic viscera and the feet were well understood, as shown, for instance, in the stoppage of the menstrual flow from getting the feet wet, and in the effect of bringing it on by dipping the feet in hot water. In males, the relation between the genito-urinary apparatus and the feet was especially marked. In the same way, there were associations between the feet and the circulation of the pharynx and larynx, and it had even been proposed that children affected with enlarged tonsils should be allowed to go with bare feet, in the hope that the condition might be thereby relieved. Still more intimate were the relations between the nape of the neck and the nasal cavities. Persons suffering from chronic nasal catarrh were often susceptible to influences which had no effect whatever upon others.

As regards the matter of treatment, there were very

few vaso-motor tonics or strengtheners, and there was nothing, in Dr. Thomson's opinion, which could compare with cold as a remedial agent. It was very useful to apply cold water to the nape of the neck on rising in the morning, especial care being taken that the hair should not become even dampened. Sponging of the throat was also excellent, and these cold applications should be kept up for a long period of time. The back of the neck and shoulders should also be well rubbed with olive oil. The second indication was to protect the cutaneous surface against exposure. As in rheumatism, woollen night-shirts and sheets were of great service. During the day-time, also, woollen garments should be worn, and a perforated buckskin shirt, with a comparatively thin woollen under-shirt, he regarded as far superior to any thick flannel. It should be left off only during the heat of summer. The same good results from the wearing of buckskin were met with in various other chronic diseases.

The second principle of treatment, as had been mentioned, was local disinfection. People were protected against the attacks of morbid bacteria only when the forces of life were maintained in a vigorous condition, and the mucous membrane of the air-passages was constantly exposed to atmospheric invaders. The most practical deduction from the matter was that, in chronic disease of this kind, we were first to strengthen cell and nerve nutrition, and, secondly, to use disinfectants by direct application. One reason why our methods of disinfection were at present so inefficient, was that it was impossible to keep up such measures for any length of time together. Such a permanent disinfectant, however, we had in the air of the ocean. It was undoubtedly true that a considerable number of cases were to be attributed to malformations, either natural or acquired; but in those which were not, it was important to know what agents ought to be used. In his opinion, the carbolic acid class, including all coal-tar derivatives, were best for the suppurative diseases. In necrotic cases, on the other hand, remedies of the chlorine group, including bromine, iodine, and sulphur, were indicated, and insufflations of bismuth and calomel had long been used.

Dr. H. H. CURTIS, having remarked that so-called chronic post-nasal catarrh, unaccompanied by stenosis, did not exist, went on to speak of the great value of chromic acid, which, for some time past, he had used, to the exclusion of all other escharotics. When this was applied to the turgescent or hypertrophied bodies, it not only had a most marked beneficial effect upon the parts immediately concerned, but also the vocal apparatus of the patient. Hence such applications were of special service to singers, actors, and others obliged to use the voice in public. This was a reflex effect, and there could be no doubt that there was a distinct correlation between the turbinated bodies and the larynx. In illustration of this point, Dr. Curtis related the case of a prominent operatic prima donna, who presented herself for treatment with a slightly congested condition of the vocal bands. He applied chromic acid to the turbinated bodies, and there was at once a marked improvement in the voice. So much pleased was the patient at the effect thus produced, that on two occasions afterward she came on from Philadelphia, between her performances, expressly to have the application made; and whenever he repeated it, it was always successful in restoring the lost brilliancy of tone. His practice was to apply the

agent in crystallized form by means of a flat copper applicator, and afterward, wash off the parts with Dobell's spray. No bad results from the use of chromic acid, he said, had ever been published. In conclusion, he deprecated the application of strong astringents and other powerful agents to the larynx.

Dr. W. C. JARVIS said that he had always found the spray a very useful means of treatment when it was properly employed; but the expression, "pound pressure," which was so frequently heard in connection with it, meant nothing of itself. Everything depended on the diameter of the pneumatic tube used, and it was only when this diameter was mentioned, together with the amount of pound pressure, that any adequate idea of the force employed could be obtained. Cocaine could be applied more efficiently by means of the spray than in any other way. When thus used, it produced an anaemia of the mucous membrane at once, and it was always noticeable that, in painful conditions, there was a return of the pain just as soon as the anaemia thus caused disappeared. If the cocaine spray was kept up for a considerable length of time with a small tube, we could get beneficial results which could be obtained in no other way.

There were, however, a certain proportion of cases in which cocaine could not be produced, and in these, the application of rhigolene was to be preferred when highly congested growths of the turbinated bodies were to be operated upon. A few seconds was all that was necessary to produce profound rhigolene anaesthesia, and, if a thick covering with any suitable unguent was made use of to protect the parts during the operation, the application of these agents was not attended by any unpleasant results.

The spray was also very useful for cleansing purposes. With a coarse spray, all the advantages of the douche could be obtained, while the hearing was not endangered, as was sometimes the case when the latter was employed. He was in the habit of using ten pounds' pressure with a tube one-eighth of an inch in diameter for a coarse spray, and with a tube of extremely small diameter for a fine spray. There was no method yet devised by which powders could be so satisfactorily applied to the upper air-passages, because in no other way could they be finely subdivided. There was, however, only one agent that was really tolerated in the form of powder, and that was iodoform. Even boracic acid or bismuth was not well borne by the mucous membrane of the upper air-passages, as could be readily tested, even when the latter was in a normal condition.

Chromic acid, he thought, should never be applied for turbinoid turgescence, but for papilloma it was excellent, and in papilloma of the larynx it was really a specific. Nitrate of silver he considered of more or less service in subacute laryngitis, and it was an especially useful agent for mucous patches. By forming a covering and protection for the ulcers, it permitted them to heal. As to surgical procedure, compared with other methods of treatment, he thought it a well-established fact that it was not really worth while to keep on making topical applications for an indefinite period, when, at a single sitting, one could remove the whole trouble. What, then, was the use of worrying with chromic acid, nitrate of silver, or the galvanocautery, Dr. Jarvis asked. The problem to be solved was merely a question of nasal drainage, and he claimed

that there was not a hyper-secretion, but that the trouble was due to distortion of the nasal planes and gutters. The so-called hyper-secretion resulted simply from accumulation, and when the nostrils were permitted to be flushed by the natural secretions, this entirely disappeared. The indication was, therefore, to remove all existing obstruction.

In conclusion, he stated that, in atrophic rhinitis, a cure could not be effected; great relief could be given by means of thorough cleansing and the use of unguents, especially vaseline, applied with the spray. In this manner, patients whose life had been a burden often for many years, on account of the intolerable stench attending the condition of the nasal passages, had, by the simple use of the deturgent douche and vaseline, been enabled to go once more into society without rendering themselves offensive to all around them. This practically constituted a cure in this incurable dry atrophy of the nasal passages.

#### AMERICAN ASSOCIATION OF GENITO-URINARY SURGEONS.

FIRST ANNUAL MEETING. Held at the Laurel House, Lakewood, N. J., May 17 and 18, 1887.

##### FIRST DAY.—MORNING SESSION.

The meeting was called to order by the PRESIDENT, DR. E. L. KEYES, of New York, at 11.30 A. M.

##### THE PRESIDENT'S ADDRESS.

DR. KEYES, in his address of welcome, first alluded to the circumstances which had led to the formation of the Association. Then speaking of the objects of the Association, he said he need not enter into the question of specialism as distinguished from general medicine and surgery. That distinction was being made for us by the circumstances of the times. The concentration of labor certainly yielded more perfect results than its general distribution. There was a field ready, and those who wished might enter in and work. Because a man belonged to this Association did not imply that he at all confined his ability to its peculiar line of study; but it furnished to him an arena in which he might develop his ideas and display the work he had done under the keen criticism of minds familiar with the subject-matter treated, and capable of still further refining, by their discussion, the quality of his work and enhancing its value.

##### A FEW STATISTICS ON THE COMPARATIVE FREQUENCY OF THE CHANCROID.<sup>1</sup>

DR. F. B. GREENOUGH, of Boston, read a paper with this title. He referred to the marked individuality that was given to the chancroid by the textbooks, in spite of which the great difference in the statistics by different observers would show that they must have used a different system or classification. Throughout this divergence of statistics, however, two facts appeared. First, that this lesion had diminished in its relative frequency to the true chancre with the exception of two periods in Paris, that is, during the war and siege (1870-1871) and during the exposition (1875), and that it occurred more frequently in hospital than in private practice. Dr. Green-

ough's records at the Boston dispensary from July 1, 1873, to March 31, 1887, gave a total of 1493 cases, of which 391 were chancroids, 219 true chancres, 931 doubtful, and 52 cases are herpes progenitalis; making the chancroid stand in proportion to other lesions in the ratio of one to three. These records were not satisfactory, as they showed only the diagnosis made at the time of the first visit. In private practice, out of 100 cases seen, ten were chancroids, sixty-three were true chancres, thirteen were doubtful, and fourteen were herpes progenitalis, being a ratio of one to ten. The diagnosis in these cases was much more reliable. Both sets of cases showed diminution in the frequency of chancroid.

DR. F. R. STURGIS said that according to his observation in Charity Hospital, New York, and dispensary practice, the number of cases of chancroid compared with those of chancre were diminishing.

DRS. R. W. TAYLOR, HYDE, MORROW, and ROCKWELL had observed a diminution in the relative frequency of chancroid to chancre. Dr. Hyde thought the need of time in which to form an opinion whether a given lesion would or would not be followed by the manifestations of syphilis should be more generally recognized. Dr. Otis did not agree in so general a condemnation of the cautery. When used early it was of benefit; used late it might do harm. The President agreed in the remarks made regarding statistics, but he expressed his belief in the virulence of chancroidal pus as compared with ordinary pus. He agreed with Dr. Otis that cauterization of virulent sores within the first ten days was good practice. Dr. Greenough closed the discussion.

##### SUPRA-PUBIC CYSTOTOMY FOR VESICAL TUMORS AND LARGE CALCULUS; A RECORD OF THREE CONSECUTIVE SUCCESSFUL CASES, WITH COMMENTS UPON VESICAL SUTURE AND A SUGGESTION FOR DRAINAGE.

The President read a paper with this title. He advocated supra-pubic cystotomy for vesical tumors, for certain foreign bodies, in cases of very large stone, and in certain exceptional instances for exploration. The method should not be adopted as the usual one in stone. He gave statistics showing that it was especially objectionable in children. He had operated for the relief of large fibro-papilloma, for flat villous growth, and for a large calculus. He described his way of dealing with hemorrhage and of applying the vesical suture. A double-curved retractor was exhibited, and a description given of his method of effecting perineal drainage by puncture, probe, and catheter, making only a small perineal incision. The drainage is considered by Dr. Keyes a most essential step in the operation, and the one feature which makes vesical suture safe and likely to be generally effective; while drainage in the perineum avoids one of the discomforts of supra-pubic section, namely obstinate fistule.

He prepares a 30 French red-rubber catheter by passing a string through it. The string being knotted inside the tip. This he passes by means of a long probe inserted through a puncture made upon a broadly-grooved staff, and by aid of a finger in the rectum thus entering the draining catheter through a hole only just as large as itself.

The paper was discussed by DRS. CABOT, ROCKWELL, BRYSON, and OTIS.

<sup>1</sup> To be published in a subsequent number of the Journal.

DR. A. T. CABOT, of Boston, read

A CASE OF HYSTERECTOMY FOR THE RELIEF OF PYELITIS FROM OBSTRUCTION.<sup>1</sup>

In the absence of the author, the secretary read a paper by DR. GEORGE CHISHMORE, of San Francisco, entitled

SOME CASES OF PYELITIS IN WHICH FREQUENT AND PAINFUL MICTURITION WAS THE CHIEF SYMPTOM.

Two cases in particular were cited to call attention to the fact noted in the books, but not sufficiently emphasized, namely, that frequent and painful micturition might be so pronounced a symptom in pyelitis as to mislead the experienced observer as to the nature of the case, and cause him to address treatment to the bladder alone, while the real malady was in the kidneys. In one of his cases in which frequent and painful micturition was the chief symptom, the man had sustained a violent muscular strain in the region of the kidney, and for some years afterward suffered in the extreme, and was treated for cystitis by some of the most distinguished specialists; but finally the abscess of the kidney discharged, and the patient recovered.

In the second case, treatment was directed to presumable cystitis, and at the autopsy the kidney was found riddled with abscesses. He asked, how many times has the healthy bladder been subjected to every variety of persistent treatment while disease of the kidneys has gone on, only shown to be present by post-mortem examination?

He believed that in many cases the diagnosis of pyelitis could be made only by exclusion.

FIRST DAY.—EVENING SESSION.

ON HORNY GROWTH OF THE PENIS, WITH EXHIBITION OF A REMARKABLE CASE.

DR. J. H. BRINTON, of Philadelphia, read the paper, exhibiting a specimen, and referring to those on record. His specimen was from a man on whose penis a horn had existed more than four years, having started from a wart. The wart had itched occasionally and the patient had scratched it for this reason. Gradually it turned into horny substance. It caused no trouble excepting mechanical interference with coition. The horn sprang from the base of the glans, at the coronary border, and was attached to both the glands and prepuce, it was one-and-seven-eighths inches long, one-and-three-eighths inches in circumference; it was curved forward. A peculiar feature in this particular case was the fact that a horny plate surrounding the meatus almost occluded the meatus, so that the urine passed only in drops. The urethra behind the horny plate was not contracted. The horn was cut off and the man left the hospital after about three weeks.

The rarity of horny growths upon the penis was somewhat remarkable. He was surprised to find only fourteen cases recorded in English, German and French literature. A few more cases had been vaguely alluded to. They occurred either as well-marked projecting horns or as rough, flat, horny plates, occupying the glans penis; they were sometimes multiple. The longest on record was three inches.

DR. CABOT had seen a horn, perhaps the size of the thumb-nail, occupying the dorsum of the glans penis,

<sup>1</sup> See page 517 of the Journal.

in a patient of Dr. Bigelow's, about twelve years ago. He could not say whether it had been reported.

DR. J. P. BRYSON, of St. Louis, then read a paper,

ON THE CHOICE OF OPERATION FOR THE REMOVAL OF VESICAL CALCULUS IN CASES COMPLICATED BY PROSTATIC OBSTRUCTION.

It seemed strange to the author how little influence prostatic enlargement has upon the cutting or crushing operation, for stone in the bladder. He believed that very rarely was section made purely for prostatic reasons, that is, with the intention not only of removing the stone, but for reducing the size of the prostate as well, and thus reducing in intensity, at least, the causes which were the most active in the production of stone, as well as lessening the sufferings of the patient in after years. Since 1884, he had operated for stone by prerectal section in four cases, all complicated by a large hypertrophic prostate gland, and had had opportunity to observe one other similar case in the practice of a friend. The age of the patients varied from sixty-five to seventy-four years. The operation in each case was successful. In one of his cases he had occasion again to make an incision and enter the tip of his finger, having failed at the first operation to entirely evacuate all the fragments; in two others opportunity to remeasure the size of the prostate was offered during an operation for return of the stone. In one case he estimated the reduction in size of the prostate after the first operation, to have been about one-third in its length, and in the other about one-fourth: in none was there now any residual urine of importance. He did not believe that any other operation for removal of the stone would have been attended by so marked reduction in the size of the enlarged prostate.

The PRESIDENT remarked that while the success of the cutting operation in the cases reported by Dr. Bryson, and occurring in old people, had been all that one could ask, yet this operation was shown by statistics to have a much larger mortality in the aged than litholapaxy. Whatever the effect of the cutting operation upon the size of the prostate, he thought we should do the crushing operation first, if it were practicable, as it was much less dangerous, and if it failed to relieve the symptoms, to consider afterwards the propriety of any other procedure. He regarded Dr. Bryson's paper as very suggestive.

DR. BRYSON said that in none of his cases was the cutting operation the operation of choice. The effect upon the prostate having been noticed, he thought it was worthy of consideration. The discussion was participated in by Drs. Otis and Cabot.

(To be continued.)

## Recent Literature.

*De l'aphasie et de ses diverses formes.* Par le Dr. BERNARD. 8vo. pp. 271. Aux bureaux du Progrès Medical. Paris: 1885.

This is the work of one of Charcot's pupils, and is based largely upon work done at the Salpêtrière under his direction. The author has studied the literature of the subject very fully, as is shown by the large number of references, and the observations on the cases quoted have been made with the greatest care, and are of the utmost interest, yet the work as a

whole, is not very satisfactory. After a preliminary consideration of the history of the subject, and of the subject of speech and its localization, the author discusses the different forms of aphasia under the following headings: Word-blindness, word-deafness, aphemia (motor-aphasia), agraphia, and the mixed forms of aphasia. He scarcely mentions paraphasia, however, and his grasp of the whole subject fails in comprehensiveness. Although his individual observations are interesting, he does not give the ordinary reader a very clear or systematic conception of one of the most difficult disorders that may arise in diseases of the brain, and therefore the work will appeal only to those who desire a careful clinical study of a number of cases of the different forms of aphasia.

*A Compend of Diseases of the Eye: Including Refraction and Surgical Operations.* By L. WEBSTER FOX, M.D., etc., and GEO. M. GOULD, A.B. pp. 148. Philadelphia: P. Blakiston, Son & Co. 1886.

The above work is the eighth in a series of *Quiz-Compend*s published by the above firm, and does not claim to be an elaborate treatise on ophthalmology, its object being "to supply the medical undergraduates with the most notable points concerning the diagnosis and treatment of ocular disorders, whether pathological or refractive." To compress the whole of ophthalmology within the above limits, resolves the book into a series of definitions of technical terms and diseases, and an empirical statement of the treatment of these various diseases. The book is written in a clear and forcible style, and every word it contains has reason for its insertion. A large proportion, sixty-two pages, is devoted to refraction. This is as it should be, as refraction is rapidly becoming a subject in which the general practitioner should be able to make a diagnosis, at least. The chapter upon operations is clear, concise and accurate.

M. S.

*A Treatise on Simple and Compound Ophthalmic Lenses, their Refraction and Dioptric Formulae.* By CHAS. F. PRENTICE. pp. 40. New York: James Prentice & Son.

This is a book which strives to explain the refraction of the various lenses used by ophthalmic surgeons without recourse to mathematical formulæ but by graphical means. The diagrams are models of neatness, clear, and very nearly explain themselves, but the text is not always an aid to the diagrams; this is more especially the case in the opening chapter, in the method of determining the direction of a refracted ray. The diagrams in the chapter upon asymmetrical surfaces showing two cylindrical surfaces upon one side of a lens, are a very clear and simple demonstration of a subject which has been much befogged in some recent ophthalmic literature. There are appended to the book tables of crossed cylinders and their spherocylindrical equivalents which will be handy for ready references, although the last line in the first table has an error of 0.25 D. in each field.

M. S.

*The Functions of the Brain.* By DAVID FERRIER, M.D., LL.D., F.R.S. Second edition. Re-written and enlarged, with 137 illustrations. 8vo. pp. xxiii, 498. New York: G. P. Putnam's Sons. 1886.

The present edition of Dr. Ferrier's well-known work "has been almost entirely re-written," and "a good deal has been added" since the first edition appeared in 1876; but the author boldly asserts that "the principal doctrines formerly advocated are main-

tained in all essentials unchanged." During the ten years that have elapsed, Dr. Ferrier has remained at the head of English investigators, but in that time Goltz has attacked, with some show of proof, the whole theory of the localization of motor centres in the cerebral cortex; Munk has asserted that those centres were, in part at least, of a sensory nature; Fritsch and Hitzig have continued their investigations; Franck and Pitres have published various observations; Exner has studied the whole subject from the standpoint of human pathology; and Luciani and Seppilli have published, almost coincidently with the present volume, the result of their long-continued observations. Moreover, these various observers, as careful as Dr. Ferrier in their experiments, and far more cautious in their judgments, are still in doubt as to the certainty of their knowledge of the functions of the brain. That in the convolutions about the fissure of Rolando are situated the centres for motion, few to-day will deny, but their exact location and limitation is still an open question, and few of the observers on the Continent will admit the minute localization of the functions of the cortex described, ten years ago, by Dr. Ferrier, and still maintained unchanged by him and his pupils. Furthermore, Dr. Ferrier's methods of investigation are not to be accepted without question. It is a matter of grave doubt whether the electrical stimulation of the brain, which is Ferrier's favorite method, can be limited with sufficient exactness to be of value. Most observers believe that the current is so much diffused as to render the results uncertain. Nor does the actual cautery commend itself to many as the most accurate method of destroying brain tissue. These, however, are the methods which Dr. Ferrier chiefly employs.

We have space to comment especially upon but one portion of the volume—the section on the visual centre. Dr. Ferrier's zeal against Munk leads him to deny that lesion of one occipital lobe can cause hemianopsia, or that lesion of both lobes can cause blindness, and he affirms that "there is not on record a single case of cortical lesion, limited to the occipital lobe, in which hemiopia has occurred." The centre for vision is placed in the angular gyrus and the occipital lobe, the former having most to do with monocular vision, the latter with vision of one-half of each retina. He supports, with but slight variation, Charcot's old theory of the double decussation of the optic tracts. His own experiments, however, seem to us to fail to sustain his position, and the whole section is an instance of false reasoning and hasty judgment, that mars the work. The proof of Munk's hypothesis, given by Seguin at an earlier date than some of the references in the present volume, is disregarded.

Much, however, in the way of assertion and dogmatism may be pardoned to a man who has done so much for the advancement of our knowledge as Dr. Ferrier has already done. The present volume, though marred at times, as we have said, by hasty conclusions and excessive dogmatism, is still full of valuable work. Dr. Ferrier has not only given his own investigations, but he has given an admirable and exhaustive review of the work of others. The volume before us is unsafe for the student beginning the study of cerebral localization; the methods of research are at times defective, the conclusions are not final; yet it is a work essential for the advanced thinker, and a most important contribution to our knowledge of the functions of the brain.

THE BOSTON  
**Medical and Surgical Journal.**

THURSDAY, JUNE 2, 1887.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 91 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HIRD,  
 91 BOYLSTON STREET, BOSTON, MASS.

### DEATH OF PROFESSOR VULPIAN.

In the recent death of Professor Vulpian, whose decease on the 18th ult., in the sixty-first year of his age, was recently announced by the cable, France has lost one of her greatest men of science, who was alike noted as a naturalist, as a physiologist and as a physician.

Vulpian's first great work consisted of a series of lectures on "Comparative Physiology," delivered in 1864, at the Museum of Natural History, and from the chair so long and so ably filled by Flourens. This course of lectures was afterwards published under the title: "*Leçons sur la Physiologie Generale et Comparée du Système Nerveux*," and has had a world-wide popularity. Multitudes of class experiments, related in a peculiarly vivacious style, give this book an extraordinary interest; the various vexed problems of innervation and cerebration receive a new light from comparative physiology as expounded by Professor Vulpian, while a sense of the essential unity of the whole animal kingdom pervades the work.

Next appeared two smaller treatises on "Digestion" and on the "Functions of the Liver"; but the great work of Vulpian is unquestionably his "*Lessons on the Vaso-Motor System*," which appeared in two volumes in 1875. Too much can hardly be said in praise of this work, which is unquestionably one of the most original productions of this age. Here, the most abstruse subjects of physiology are treated in an uncommonly lucid and felicitous style, and illustrated by experiments, many of which were of a very difficult nature. Much has been accomplished by the conclusions to which Vulpian's studies led, in the way of dissipating erroneous notions respecting the rôle of the vaso-motors, and of inculcating right views as to the part which this portion of the nervous system plays in the phenomena of sleep, inflammation, glyco-genesis, hysteria and epilepsy, animal heat production, etc. It is surprising that the work has never been translated.

The work on the vaso-motors was followed by the

"*Leçons sur les Substances Toxiques et Médicamentenses*," a treatise replete with interesting observations (the result of personal experimentation), on the action of medicines; and the "*Clinique Médicale de l'Hôpital de la Charité*," a work full of practical interest to the physician, making up a "year book" of Charity Hospital, in which all the most interesting cases during one year's attendance are recorded and commented on.

Continuing his studies in experimental pathology, Vulpian's next and unfortunately his last work was his two volumes on "*Diseases of the Nervous System*"; the first volume appearing in 1879, the second, which completes the spinal cord, the present year. Vulpian intended to have added to these a third volume on "*Diseases of the Encephalon*."

As a lecturer, Vulpian was always popular; as an experimental physiologist, he was hardly excelled, even by Claude Bernard; as a writer, his style is characterized by vigor, vivacity and clearness—even an occasional diffuseness may be readily forgiven in a writer who is especially solicitous to be understood.

Professor Vulpian was a member of most of the learned societies, and for several years Dean of the Faculty of Medicine, until, through political influence, he was replaced by Beclard, in whose recent death, moreover, France has lost another of her great physiologists.

### ANTIPYRINE AS AN ANALGESIC.

ANTIPYRINE, whose remarkable properties as an antithermic, though everywhere recognized, are still inferior to those of the more recent candidates for favor, has lately come to the front as a remedy of the first utility in allaying pain.

According to Germain Sée, its analgesic properties are especially marked in painful rheumatic or gouty arthritis, and in nervous states characterized by pain. He administered antipyrine to fifteen rheumatic patients, with or without fever and hydrarthrosis, who had been treated ineffectually by punctiform cauterizations and salicylate of sodium. The pain, with the swelling of the joints, disappeared in a few days. It was, however, necessary to continue the administration of the antipyrine in smaller doses for about a week after amendment manifested itself, in order to guard against relapse.

The same happy result was observed in cases of acute gout, whether grafted or not, or chronic gout, with uric deposits. The antipyrine, given in grammes-doses, from four to six times a day, caused disappearance of the pain and swelling in less than a week, and without the heart or the kidneys suffering any damage. But it is (according to the same authority) in nervous troubles of the sensibility that antipyrine produces the maximum of action. A first series of fourteen observations, relative to pains in the head, pertains to four cases of facial neuralgia, one of which was inveterate, and all of which yielded rapidly; to six of chronic mi-

graine, of which five were at once benefited by a two-gramme dose (thirty grains) of antipyrine; to four of headache, due to various causes, in all of which relief was obtained.

A second series comprehends eighteen cases of neuralgia or neuritis and myalgia, to wit, sciatica, neuritis from diabetes or zona, and of which cases two-thirds experienced immediate relief; cases of lumbago, some of long standing, and muscular or nervous pains of a similar character in different parts of the body (neuropathic pains, pains from strain or overwork). The results of antipyrine in these cases were gratifying.

Several months ago, Lépine, of Lyons, announced that antipyrine was of singular utility in controlling the lightning pains of locomotor ataxia. *Sée* confirms this observation of Lépine, and finds antipyrine to be much better for these lightning pains than the newer medicament, antefebriue.

In diseases of the heart and aorta, attended by those paroxysms of *angina pectoris* which often so tax the resources of the physician, large doses of antipyrine have been found to be signally efficacious. *Sée* reports six cases of aortic disease, and three of aneurism, characterized by painful crisis, which yielded to gramme-doses of antipyrine, repeated every hour, until three, four, or five doses were taken. The medicine is generally well borne, and rarely causes vomiting, or any other unpleasant effect. Exceptionally, there may be uncomfortable diaphoresis and depression under the larger doses. Individual idiosyncrasy is a factor to be borne in mind in the administration of any drug, and especially of a comparatively new one.

#### A TRAINING SCHOOL FOR MALE NURSES.

A BUILDING designed as a training school for male nurses is to be erected by Mr. D. O. Mills, in the grounds of Bellevue Hospital, at an estimated cost of \$80,000. It is to be organized on the same general plan as the schools for female nurses now in such general operation. The architectural plans have been approved by the Commissioners of Charities and Correction, and the James R. Wood anatomical and pathological collection is to be placed in a large apartment at the top of the building, which will be separated from the rest of it by a fire-proof wall. On the floor below quarters will be provided for the house-staff of the hospital. Part of the second floor will be given up to the sleeping-rooms of the male nurses, and the rest devoted to lecture-rooms, while the general offices of the institution will be on the ground floor. By a happy coincidence, on the very day that the Commissioners were ordered to tear down the old museum building which has contained the Wood collection for many years, the generous offer of Mr. Mills was made through his friend, Mr. W. H. Osborn, whose wife presented the noble Sturgis pavilion to Bellevue Hospital.

#### THE MEDICAL REGISTER FOR NEW ENGLAND.

PHYSICIANS belonging to the State medical societies of New England, were reminded, last week, that they might look for a new edition of the *Medical Register* in the fall. Dr. Brown, who has, for so many years, prepared this handbook, promises that this edition—filled from cover to cover with valuable information concerning societies, hospitals, schools, and the other matters which the physicians, dentists and pharmacists so frequently need to know about—shall in no way fall behind those already put forth.

Very naturally the earlier editions are out of date; that of the coming autumn will be brought as nearly to the facts as they exist to-day as is possible. It is not to bespeak for the book the cordial sympathy of all medical men as *purchasers*, that we now call attention to it, for their own interest will do that; but we desire to urge each one to do his share in *giving information*. In the same way that Dr. X., among the New Hampshire hills, may desire information concerning the office hours of Dr. Y., the specialist in Boston, or the method of getting a patient into a hospital, or the name of the army medical officer at Fort Warren, so Dr. Y. may wish to know the name of a reliable man in his very town and be glad to learn his qualifications, or the hospital in Boston may be glad to send a patient to a quiet retreat in the country for change of air and scene.

This composite end can be attained if each one and every one will, in turn, give information concerning himself, his hospital or dispensary, his local society, his charitable institution, or home, or retreat. Many new foundations have been created in the past few years; these new factors in the Armamentarium of the practitioner should be known, and can best be known through the agency of some general work on the subject like the *Medical Register*. What you would be glad to know of others, let others know of you.

#### MEDICAL NOTES.

—It is said, that there are twenty-seven distinct schools of "mental healers" in Chicago.

—The United States consul at Callao forwards to the Treasury Department a despatch from Valparaiso, dated April 12, 1887, as follows: "It has been officially declared that the cholera has disappeared from this port. There are only one or two isolated cases," also one from Santiago, dated April 13th, saying: "During the last twenty-four hours there have been four new cases of cholera, and four deaths in the suburbs of this town." He adds: "Peru has so far escaped the pestilence, and we are in hopes that all danger has passed. But the same strict sanitary regulations and precautions are still observed, and the board of health has given no expression of a change of programme since the information above referred to was received. The health of Lima and Callao is satisfactory."

—Some searching questions were asked at a recent sitting of the Austrian Reichsrath, by a Herr Pernerstorfer, according to the *British Medical Journal*, which reflected seriously on the management of the Vienna Allgemeines Krankenhaus, which is the largest hospital in Austria, and one of the largest in Europe, containing, as it does, over 2,000 beds. The charges, though denied in the first instance, are said to have been proved to be substantially correct. The complaints bore principally on the defective commissariat arrangements. These are reported to be at all times unwholesome and scanty, and the patients are alleged to have been kept for days without any food at all. In the whole establishment, there is but one bath, and the nurses, of whom 219 are women, and 19 men, are accused of having practised systematic extortion on the wretched patients, and to have ill-treated those who were unable or unwilling to pay. The Government promised to make a searching inquiry into the system of management, with the object of remedying whatever might be defective.

—A correspondent writing from Boston to the *Therapeutic Gazette* says: "I have never yet seen in any work on materia medica, therapeutics, or toxicology the following method of emptying the stomach in cases of opium-poisoning. I have found it rapid and effective in two cases. It is entirely mechanical, but acts in a very short time. Four to six ounces of sodii bicarb. stirred well into a goblet of water and swallowed. In a few moments follow it by a goblet of good vinegar. The result is, that a perfect fountain of the mixture, with the contents of the stomach also, flies out of the mouth into the basin. I first heard of it from Dr. Henry G. Clark, of this city."

To this the editor replies: "We think that this method of causing emesis has not been widely practised in the profession. It is certainly very heroic, and to one who has never seen the play of this human geyser, somewhat appalling. Probably in a strong, vigorous patient, the plan would not be able either to produce fatal strangulation or rupture of the stomach."

—The following mixture to stop toothache is given in the *Therapeutic Gazette*. It forms an oily liquid, and when introduced into a tooth-cavity, is said to be very effective:

Camphor	gr. lxxv.
Chloral hydratis	gr. lxxv.
Cocaine murici	gr. lv.

#### BOSTON AND NEW ENGLAND.

—The eleventh annual report of the Sea-shore House, at Winthrop, for the season of 1886, shows that the whole number of inmates was 202, of which 152 were patients. The chief diseases represented were cholera infantum, 15 cases; diarrhoea 36; dysentery 7; and debility 58. 110 were "cured," 29 relieved, 4 not relieved, and 9 died. 4 of the deaths were from cholera infantum, and of the 9 who died, 7 were hand-fed. The receipts for the year were \$3,137. Contributions may be sent, for this most worthy charity, to Elliott Russell, treasurer.

—The number of patients admitted during the year to the Washingtonian Home for inebriates, Albert Day, M.D., Superintendent, was 379 (last year 335); of these 163 were natives of Massachusetts, 94 of other States, and 122 of foreign countries. 326 were residents of Massachusetts, and 211 were married men. There were 95 cases of delirium tremens and one death; (last year, 73 cases and two deaths). The receipts from patients were \$11,900.78, which is about the same as in 1885, and \$1,150 less than last year; and the average cost of each patient was \$31.40, \$7.56 less than last year. The expenses of the year, as shown by the Treasurer's report, were \$12,240.07.

—The Barnstable County District Medical Society held its annual meeting at Dennis, May 10th. Officers were elected as follows: Dr. Clement of Centerville, president; Samuel Pitcher of Hyannis, vice-president; F. A. Rogers of Brewster, secretary; C. M. Hurlbut of South Dennis, treasurer; councillors, Drs. Doane, Munsell and Pitcher.

#### NEW YORK AND NEW JERSEY.

—Dr. Thomas F. Rochester, one of the leading physicians of Buffalo and Western New York, died May 24th, of Bright's disease. He was born in Rochester in 1823, and graduated from Geneva College in 1845. He received the degree of M.D. from the University of Pennsylvania in 1848, and afterwards continued his medical studies in the principal European cities for some time. In 1851 he established himself in New York, but, two years later, left the city to accept the chair of Principles and Practice of Medicine and Clinical Medicine in the University of Buffalo. Dr. Rochester was a prominent medical writer and consultant, and during the late war was appointed by President Lincoln to inspect the Union field hospitals. In 1875, he was elected President of the Medical Society of the State of New York, and up to the time of his last illness he was a leading Fellow of the New York State Medical Association, of which he was one of the founders.

—Six physicians on the visiting staff of the Jersey City Hospital have handed in their resignation to the Police Board of Jersey City, the cause of this action being the interference of the latter Board in increasing the staff by the appointment of eight additional physicians and surgeons. This leaves only two members of the old Medical Board, Dr. Reeve and T. R. Varick.

—James Preston died recently at Browntown, New Jersey, at the advanced age of one hundred and five years and five months. Up to the time of his death, he managed and directed the work on a farm of two hundred acres, and when he was in his one hundredth year he walked home from South Amboy, a distance of eight miles, in less than two hours. He was never known to have a sick day, and is said to have attributed his old age and good health, to some extent, at least, to his daily practice of taking a "night-cap" of good, old Jersey apple-jack before retiring.

## GERMANY.

— Prof. A. Vogel has been made honorary professor at Munich.

— The Sixtieth Session of German Naturalists and Physicians will be held at Wiesbaden September 18th to 24th next.

— Prof. Wm. Hack, of Freiburg, the renowned laryngologist and rhinologist, died recently from an attack of apoplexy.

— Dr. Wolfhugel, for some time in the Imperial Health Department of Berlin, has been called to Göttingen as Professor of Hygiene.

— Dr. Nathaniel Lieberkühn, professor of anatomy at the University of Marburg, and son of the discoverer of Lieberkühn's glands, died recently at the age of sixty-five.

— Prof. A. v. Kölliker, of Würzburg, Professor of Anatomy, and late President of the Anatomical Society, has been given the degree of Doctor of Law, by the University of Edinburgh.

— The German Association of Public Health will convene in Vienna September 26th to October 28th, to meet with the International Hygienic and Demographic Congress. The latter will meet in the University building. All governments are requested to send delegates.

— The South German and Swiss Otological Association met in Vienna recently in the clinic of Prof. Pollitzer, which gentleman was president of the Association. As many of the Association were his students this was made the occasion of the celebration of his twenty-fifth year as teacher.

— Prof. Olshausen, formerly of the University of Halle, has been added to the faculty of the University of Berlin, to fill the chair vacated by the lamented Schroeder. Prof. Olshausen took up his work on the 5th of May, and was greeted by an amphitheatre crowded to the last place. He opened with a feeling reference to his predecessor, his worth as a man, teacher, writer and gynecologist. Prof. Olshausen has been succeeded at Halle by Prof. Kaltenbach, of Giessen.

— The Anatomical Society, founded in Berlin, September last, held its session in the Anatomical Institute of the University of Leipzig recently. The meeting was, for so young a society, quite well attended and interesting. The programme was as follows: "The Asymmetry of the Face," Dr. C. Hasse, of Breslau; "Observations on the Brain of Man," Dr. M. v. Lenhosek, of Pesth; "The Mechanism of the Wrist-joint," Prof. Braune, of Leipzig; "Communication on Embryology," Prof. Ruckert, of Munich; "Glands," Dr. Stohr, of Würzburg; "The Development of the Pigment of the Skin and the Nourishment of the Epidermis," Dr. Karg, of Leipzig; "A Chapter in Vertebral Spermatogenesis," Dr. Banda, of Berlin; "The Place of most Acute Vision in Fish Eyes and Experiments with Hematoxylin in Coloring

Matter," Dr. Schieferdecker, of Göttingen; "The Traces of Parietal Eyes in Man," Professor Bardeleben, of Jena; "Morphological Contemplations," Dr. Albrecht, of Hamburg; "New Methods in the Field of Educational Embryology," Dr. Gerlach, of Erlangen. Interesting demonstrations in great numbers were made by different members. Reports were made by Professors Waldeyer and His, the former of Berlin, the latter of Leipzig. Prof. A. v. Kölliker, of Würzburg, was president. The membership was 190, of which 78 were foreigners. From Austro-Hungary 23, Russia 10, Great Britain 8, Switzerland 8, Netherlands, Belgium, Scandinavia, Italy and America each 6, France 1. These consisted of 124 anatomists, histologists, and embryologists, 18 zoologists, 14 pathological anatomists, 10 physiologists, and 10 practitioners.

### DISCELLAP.

#### THE PRIMARY ANÆSTHETIC STAGE OF ETHER.

DR. JOHN H. PACKARD, surgeon to the Philadelphia Hospital writes as follows in the *Polyclinic*: "I would like to say a few words about giving ether for its first anæsthetic effect. This man is now entirely himself. He will have no vomiting, no headache, and will be perfectly comfortable. The effect of administering ether in this way is much like nitrous oxide. Its advantages are very great. A man comes into your office with a painful abscess of the finger and you propose to open it. If you give ether to full insensibility, you have to keep him in your office for two or three hours, which is a great inconvenience. If you do the operation at his house, he has three or four hours of headache and discomfort, whereas, if you give ether to the first insensibility he recovers immediately and perfectly. You can let him sit down and hold one hand up while he holds the ether sponge himself. When the hand drops you have a period of from thirty to ninety seconds, in which the man is in a state of insensibility, during which time you can open an abscess, or reduce a dislocation, or perhaps even replace a hernia. In a few minutes the man is fully recovered, and is able to walk away. I think that this method of administering ether is absolutely free from danger. It has been objected by good authorities on the subject of anæsthetics, that partial anæsthesia is always a condition of peril. Very good; but you do not keep the patient in a state of partial anæsthesia. You simply take advantage of a stage through which he must pass, and therefore you do not add in the least to the danger."

#### GROWTH OF PATHOGENIC ORGANISMS IN WATER.

THE problem, how long will bacteria of known pathogenic powers retain their vitality in potable water is one of growing importance in the development of a sound system of water analysis. The *Polyclinic* refers editorially (May, 1887) to several important communications on this, from trustworthy sources, which

have lately appeared. In the *Zeitschrift f. Hygiene* Meade Bolton discusses the subject, and also Dr. Percy Frankland in the *Sanitary Record*, and Dr. Kraus in the *Archiv f. Hygiene*. The conclusions, as might be expected, do not quite agree. Frankland has shown beyond doubt the great benefit to be derived from filtration, and his latter results show that sporeless bacilli are little likely to multiply in water, but that different species of microbes behave very differently—in other words, no general law can yet be laid down. Kraus' observations appear to be very valuable from a practical point of view. He premises very plausibly that experiments made upon sterilized water, or on samples maintained at blood heat, have but little practical bearing, and that the sample should be in the normal condition. Kraus inoculated samples of river and pump-water with well-known species of pathogenic bacteria, and noted the growth under ordinary conditions. He found that the number of the pathogenic organisms soon began to be reduced, while the non-pathogenic varieties already present in the water increased. At the end of a few days no living pathogenic organisms could be found. This result does not seem strange. Among rapidly multiplying organisms the struggle for existence must be an important factor, and in the average water the microbes normal to it will be likely to be the victors in any such struggle. Something will, of course, depend on the supporting power of the water, and in this relation the amount of the organic matter may retain some significance. Frankland states that while Koch's comma-spirillum multiplies enormously in sewage, it does not in filtered well-water; and Finkler's spirillum, which closely resembles Koch's, could not be made to live a single day in either sewage or filtered water. In this connection may be noted the remarks made by Dr. Buchanan, in the report of the London Local Government Board, to the effect that perhaps the surest protection against pathogenic bacteria will be the agency of the non-pathogenic forms.

#### AN ECONOMICAL METHOD OF PREPARING ANTISEPTIC GAUZE.

DR. GERSTER, of New York, in an article in the *New York Medical Journal* of April 2, 1887, describes his method of preparing gauze as follows:

*Gauze*—that is, *cheese or tobacco cloth*, as it is called by the trade—can be procured at any dry-goods store for a trifling sum of money. Twenty-five yards of this fabric are divided into four equal parts. Each of these is folded eight times, and the piece is rolled up loosely and tied with a string. These four pieces of gauze are next made absorbent by freeing them of their oily contents adhering to the cotton from the gin or mill. They are put into a common wash-boiler, covered with water to which a pound of washing soda or saleratus was added, and boiled for an hour. After this they are rinsed in cold water for ten minutes to free them from the soda, are passed through a clothes-wringer and placed in a stone or glass jar or an enamelled kettle, filled with a corrosive sublimate lotion of 1 to 1,000 strength, to remain therein for twenty-four hours. From this they are passed through the wringer again, and hung up to dry over night, when the air is free from dust. The string put about each piece should not be removed until the time of drying, as it will

keep the folds from getting disarranged. The dried pieces are ready for use, and will keep clean wrapped in a towel or put away in a jar.

Whenever dressings are used, suitably-sized compresses, each having eight folds of cloth, can be cut out of the piece with a stout pair of sharp scissors.

Iodoformized gauze is made by sprinkling iodoform dust from a pepper-shaker uniformly over the moist compress, and rubbing it thoroughly into the meshes between the fingers.

An excellent substitute for gauze in an emergency is common cotton-batting well soaked in a solution of corrosive sublimate (1 to 1,000). The package of batting is unrolled in an ordinary manner, and cut into square pieces of desired size. Each of these is folded into a small square and thoroughly kneaded in a wash-basin filled with the mercuric lotion, till complete saturation is evident. Well wrung out, each piece is unfolded again to its original shape, and is ready for use.

Any clean textile fabric of cotton or linen, soaked in mercuric lotion, will be a good antiseptic dressing.

#### AMPUTATIONS FOR JOINT-DISEASES WHEN LUNG TUBERCULOSIS COEXISTS.

DR. LEWIS S. PITCHER, in an interesting paper upon the above subject in the *Annals of Surgery*, reaches the following conclusions:

1. The probabilities of a spontaneous cure, or prolonged abeyance of a tubercular bone or joint trouble, as a result of expectant and palliative treatment—that is, improved hygiene, rest, counter-irritation—is much greater in children than in adults.
2. The probability of the presence or early development of lung tuberculosis in case of tubercular bone and joint affections, is much greater in adults than in children.
3. Incomplete operations, as drainage and irrigation of joints, évidement, and resections in which all of the diseased tissue is not removed, are less likely to be followed by ultimate good results in adults than in children.
4. Operative interference of a radical character is justifiable at an earlier date, in the history of a bone or joint tubercular affection, in an adult than in a child.
5. When a lung tuberculosis is present, and an operation for the relief of a coexisting bone or joint affection is indicated, as the result of such operation, the lung affection, while in some cases influenced, is more frequently temporarily checked in its progress, and in some instances is apparently entirely removed.
6. Local relapse after an operation for an osteo-arthritis tubercular disease, lung tuberculosis existing, is exclusively conditioned upon incompleteness of the operation—the fact that somewhere tubercular tissue escaped removal—and not upon any influence exerted by the lung affection.
7. In any case of osteo-arthritis tubercular demanding operation, in which a doubt exists as to the possibility of removing absolutely all the diseased tissue by the more conservative methods of arthrectomy or excision, the coexistence of lung tuberculosis would be a circumstance that would add weight to the reasons for having recourse to the more radical operation of amputation.

8. After an amputation in perfectly healthy parts, as prompt healing may be expected in persons suffering from lung tuberculosis, as after such an operation on a healthy person. Relapses at the stump do not occur even in persons with advanced lung disease.

### Correspondence.

#### ACUTE INFECTIOUS UNIVERSAL MYOSITIS.

BOSTON, May 30, 1887.

MR. EDITOR, — Since I read the report of a case of "Acute Infectious Universal Myositis," before the Section

for Clinical Medicine, Pathology and Hygiene, of the Massachusetts Medical Society (published in the *JOURNAL* of May 26, 1887), the case has been published in full in the *Berliner Klinischer Wochenschrift* for April 25, 1887. Prof. Kussmaul gives the disease the name "Pseudo-Trichinose; eine besondere Form von Acuter parenchymatöser Polio-myositis." Contrary to my statement Prof. v. Recklinghausen reports hyaline degeneration of the muscles, but no fatty or granular degeneration. I see no advantage in the name "Pseudo-trichinose," as the disease has nothing to do with trichinosis, and I should much prefer the name "Acute Infectious Universal Myositis," as first given by Kussmaul in his clinical lecture on the case, and again applied by me in my paper upon the same case, as mentioned above.

Yours truly,

HENRY JACKSON, M.D.

#### REPORTED MORTALITY FOR THE WEEK ENDING MAY 21, 1887.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Northampton . . . . .	12,896	3	0	33.33	—	—	33.33	—

Deaths reported 2,393; under five years of age 965; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 462, acute lung diseases 329, consumption 314, diphtheria and croup 152, measles 68, diarrhoeal diseases 63, typhoid fever 32, scarlet fever 27, erysipelas 13, cerebro-spinal meningitis 12, whooping-cough nine, small-pox seven, puerperal fever three. From typhoid fever, Philadelphia 13, Pittsburgh four, New York, Boston and Baltimore, three each, Richmond, New Orleans, Lowell, Lynn, Salem and Waltham one each. From scarlet fever, New York eight, Brooklyn seven, Boston four, Chelsea two, Philadelphia, Milwaukee, Providence, Cambridge, Somerville, and Salem one each. From malarial fever, New York four, Brooklyn and Baltimore three each, New Orleans two, Philadelphia, District of Columbia, Providence and New Haven one each. From erysipelas, New York six, Brooklyn three, Boston two, New Orleans and Milwaukee one each. From cerebro-spinal meningitis, New York three, New Haven two, Baltimore, Newport, Milwaukee, Nashville, Lowell, Fall River and Gloucester one each. From whooping-cough, Nashville two, New York,

Brooklyn, Boston, Baltimore, District of Columbia, Pittsburgh, and Milwaukee one each. From small-pox, New York seven. From puerperal fever, Brooklyn, Providence and Lowell, one each.

In the 22 cities and greater towns of Massachusetts, with a population of 1,036,330 (population of the State 1,941,465) the total death-rate for the week was 21.12 against 20.15 and 22.46 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,245,000, for the week ending May 7th, the death-rate was 20.9. Deaths reported 3,701; infants under one year of age 847; measles 249, whooping-cough 100, scarlet fever 45, diarrhoeal diseases 39, diphtheria 32, fever 22.

The death-rates ranged from 16.0 in Birkenhead to 34.2 in Preston; Birmingham 18.8; Bolton 16.7; Bradford 21.6; Hull 17.5; Leeds 20.7; Leicester 17.5; Liverpool 26.0; London 18.9; Manchester 31.0; Nottingham 17.2; Portsmouth 20.4; Sheffield 19.5; Sunderland 20.5.

In Edinburgh 19.0; Glasgow 22.9; Dublin 36.6.

The meteorological record for the week ending May 21, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending	Barom- eter.	Thermometer.		Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>		Rainfall.
	Daily Means.	Daily Means.	Maximum.	Minimum.	7.00 A. M.	3.00 P. M.	11.00 P. M.	Daily Means.	7.00 A. M.	3.00 P. M.	11.00 P. M.	7.00 A. M.	3.00 P. M.	11.00 P. M.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 21, 1887, TO MAY 27, 1887.

HUBBARD, V. B., surgeon. Granted leave of absence for one month, to take effect on or about June 1, 1887. S. O. 119, A. G. O., May 24, 1887.

ELDER, F. W., captain and assistant surgeon. Found incapacitated for active service by an Army Retiring Board, sick leave still further extended until further orders on account of disability. S. O. 116, A. G. O., May 20, 1887.

BURTON, H. G., captain and assistant surgeon. Granted two months' leave of absence, on surgeon's certificate of disability. S. O. 107, Division of the Atlantic. May 23, 1887.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING MAY 28, 1887.

DEANE, C. W., passed assistant surgeon. Detached from "Dale," and to Hospital, Mare Island.

HARVEY, H. P., surgeon. Orders to "Iroquois" revoked and wait orders.

DICKSON, S. H., passed assistant surgeon. Detached from Navy Yard, Washington, D.C., and to the "Dale."

WAGGENER, J. R., surgeon. Detached from the "Iroquois" and wait orders.

WHITE, STEUART S., assistant surgeon. Ordered to Receiving Ship "St. Louis," Navy Yard, League Island.

DR. JAMES G. FIELD, of Gordonsville, Va., commissioned assistant surgeon in the navy, May 23, 1887.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING MAY 21, 1887.

GOLDSBOROUGH, C. B., surgeon. Leave of absence extended to June 1st, on account of sickness. May 18, 1887.

GUTTERAS, JOHN, passed assistant surgeon. Granted leave of absence for four days, May 21, 1887.

ARMSTRONG, S. T., passed assistant surgeon. To remain in charge of service at Memphis, Tenn., until further orders, May 21, 1887.

DEVAN, S. C., passed assistant surgeon. Leave of absence extended thirty days, May 19, 1887.

CARLINGTON, P. M., assistant surgeon. Ordered to United States Revenue Steamer "Rush," May 18, 1887.

NORMAN, SEATON, assistant surgeon. To proceed to Marine Hospital, Baltimore, Md., for temporary duty, May 20, 1887.

HEATH, F. C., assistant surgeon. Granted leave of absence for thirty days, May 18, 1887.

WOODWARD, R. M., assistant surgeon. Appointed an assistant surgeon, May 20, 1887. Assigned to temporary duty at the Marine Hospital, Baltimore, Md., May 21, 1887.

#### SOCIETY NOTICE.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT.—THE SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HY-

GIENE, will meet at Huntington Hall, Massachusetts Institute of Technology, TUESDAY, JUNE 7, 1887, 7.45 o'clock. Papers: Dr. J. W. Farlow, "Cascara Sagrada, and its use in the treatment of Constipation." Dr. P. C. Knapp, "The measurement of the Galvanic current, with some remarks upon Electrodes." Dr. Albert N. Blodgett, "A Case of Agoraphobia." Dr. F. W. Page will exhibit a gall-stone which was expelled after impaction of eighteen months, (weight 23 grains).

ALBERT N. BLODGETT, M.D., Secretary.

F. I. KNIGHT, M.D., Chairman.

#### SEA-SHORE HOME. RESIDENT PHYSICIAN REQUIRED.

Applications for the position of resident physician at the Sea-Shore Home for Children, at Winthrop, Mass., will be received until June 7th. Term of service about two and one-half months, beginning about June 15th. Residence and board furnished. Additional compensation as may be agreed. Application received from graduates in medicine only. Previous experience in the treatment of diseases of children preferred. For further particulars apply from 2 to 3 P. M. to

H. C. HAVEN, M.D., 19 Exeter St.

#### BOSTON CITY HOSPITAL.

Expected Operations, June 7th, at eleven o'clock: Removal of portion of tongue and lower jaw, for malignant disease; Amputation at hip, for necrosis of femur; Amputation at hip, for hip disease; Excision of knee.

#### BOOKS AND PAMPHLETS RECEIVED.

The Curability of Epilepsy and Epileptoid Affections by Galvanism and the Phosphated and Aromatized Bromides. By C. H. Hughes, M.D., St. Louis, Mo. 1887. (Reprint.)

Transactions of the Pathological Society of Philadelphia. Volume XII. Containing the Report of the Proceedings from September, 1883 to July, 1885. Edited by W. E. Hughes, M.D. Philadelphia: Printed for the Society. 1886.

Closure of the Jaws and its Treatment. By J. Ewing Mears, M.D., Professor of Anatomy and Clinical Surgery, Pennsylvania College of Dental Surgery, Surgeon to St. Mary's Hospital. #### THE POSITION OF THE MASSACHUSETTS MEDICAL SOCIETY; ITS RELATIONS TO MEDICAL PROGRESS, TO THE COMMUNITY IN WHICH WE PRACTISE, AND TO ITS FELLOWS.<sup>1</sup>

BY GEORGE J. TOWNSEND, M.D., OF NATICK, MASS.

MR. PRESIDENT and Fellows of the Massachusetts Medical Society: After nearly four decades of active professional life, a personal experience, embracing the first promulgation of the fact that there are diseases self-limited, culminating in the triumphs of antiseptics, retrospection leads us to consider what part we have played in all this, and suggests the topic to which I would invite your attention to-day.

We are accustomed to various opprobrious epithets: We are Allopaths, Old School Regulars, banded together for our own selfish gain and aggrandizement.

In the recent attempt to change the organization of one of our best appointed hospitals, an eminent lawyer, who should have known better, asks our late much-lamented President "if he would not adopt a system of medicine which would cure fifty per cent. more patients than his own"?—a question containing two manifest absurdities, and which necessarily could elicit no answer.

The distinguished divine who graced our last annual dinner with his presence counselled us charity towards other sects in medicine, and that we should not consider it impossible for a patient to be cured by any other system than our own, as if there could be sects and systems in medicine, as there are in theology.

It would seem as if the time had come for an earnest protest against such misrepresentation, such manifestations of utter ignorance of the true scope and workings of our Society.

Our Charter, in the crude fashion of its time, sets forth the objects for which we are incorporated. In its preamble, it takes for granted that the preservation or recovery of health is essentially necessary to the happiness of society, that it "is closely connected with the knowledge of the animal economy, and of the properties and effects of medicines, and that the benefit of medical institutions formed on liberal principles, and encouraged by the patronage of the laws, is universally acknowledged."

A careful examination of the articles of our incorporation shows that they are only adapted to the carrying out of the objects set forth in the preamble. There is nothing in them, nor in the by-laws enacted under them, which indicates any intention to confer exclusive privileges upon our Fellows, unless, possibly, exemption from enrolment in the militia may be considered such a privilege. Yet many of our Fellows render good service as medical officers of our various military organizations, to say nothing of our Society's record during the Secession War.

Have we, as a body, carried out the objects of our Charter? I can only say, "circumspice." There is hardly a general charity in our State that does not number amongst its workers one or more Fellows of our Society. The strictly medical charities are largely administered by them. Our dispensaries are officered by our younger Fellows, who, fresh from their earnest

student work, devote themselves with a zeal which often imperils health, and even life, to the treatment of the squalid poor. What is their compensation? A stipend that would not pay their office-rent, and the experience they gain; and that experience is of doubtful value to the general practitioner, so different are the conditions under which disease manifests itself in those whose surroundings defy all hygienic influences, and in those who enjoy the comforts and luxuries of life.

The staff of our hospitals is composed of men who have already acquired a position for themselves in the community, many of them known to fame, with world-wide reputations. They give hours, days, months of hard work, without money and without price, their only recompense the satisfaction of relieving suffering, and of advancing medical science.

Our teachers labor faithfully and earnestly in our schools, that they may fit others to succeed them in the work they do so well themselves. Their reward is a pittance that a first-class book-keeper would scorn.

But the medical charities of our cities are evident enough, and need not be enlarged upon. What shall be said of the unobtrusive, unknown charitable work done by our Fellows in the lanes and by-ways of our Commonwealth? Some of our inland towns employ a physician by the year, at a stipend of from fifty to one hundred dollars, to attend the town poor. But a large extent of country is entirely unprovided for, with no dispensary or hospital refuge within reach. Our country physicians, then, devote much time and hard work to the relief of the suffering poor. They take long rides to most inaccessible places, enduring summer heats, and literally breasting winter's snows, without the hope of fee or reward; with no other motive than to alleviate human suffering. In times of distress, in strait of money, in the prevalence of unusual epidemics, these charities amount to a very large proportion—in instances, to not less than a fifth of the physician's yearly work. Surely, such facts as these should protect us from the imputation of selfishness and greed of gain.

In what sense are we regulars? This is an unfortunate term, its converse occurring in our by-laws, as conveying to the minds of the community the idea that the Massachusetts Medical Society enjoins upon its Fellows a definite course or system of pathology and practice, deviation from which constitutes irregularity, than which nothing can be more erroneous. The term, in its application, is, indeed, rather negative than positive. We are regular just so far as we conform to our by-laws, to which we have all given our written assent, and we are irregular when we violate those by-laws, and are guilty of practices forbidden to Fellows. Those practices are, in brief, the professing to cure diseases by any exclusive system of medicine, the advertising, or offering for sale, of secret medicines, and the pretending to cure diseases by such secret medicines, or by any secret treatment.

Are we "Old School," "Allopaths," convertible terms, as usually accepted by the public? We belong to no school whatsoever, certainly, in view of the developments in medicine within the last half-century, not to an old school. As to allopathy, what the term may mean I am sure I do not know; but if, as defined in Dunglison, it means "a method of curing disease by remedies, the action of which, in healthy man, produces morbid phenomena different from those that we observe

<sup>1</sup>Annual discourse delivered before the Massachusetts Medical Society, June 8, 1887.

in the sick person," very few Fellows of our Society would attempt such a feat as all that implies.

This suggests a proposition which underlies the very foundation of our Society, which has already been publicly proclaimed by one of our Fellows, but which cannot be too often reiterated, or too strongly emphasized, which is that there is not, never has been, never can be, any exclusive system of pathology and medicine which can formulate and apply to the modification of disease, as it occurs in its infinite variety of conditions in the human system, all the facts that natural science, pathological research, and clinical observation are every day developing and adding to our store; that whoever attempts to establish such a system begs the question, assumes that the evidence is all in, and that no new fact can be discovered which may militate against his theory. From this, as a corollary, it follows that no exclusive system of pathology and medicine, no "pathy," whatever prefix you give it, can as yet be admitted as either proven or true, nor can it ever be, until medical science is a finality, about which nothing new is to be learned.

Is not this, then, the position of the Massachusetts Medical Society to-day, as at its inception? Seeking only the advancement of medical science, it grants the largest liberty in therapeutics, leaves to the judgment of the attending physician the treatment of every given case, forbidding only pretensions not founded on established facts and exacting only fealty to our Constitution and to our By-laws. These the Society has established as the best means of furthering its objects, the promotion of the health, in consequence the happiness of the community.

A glance, suggestive only in its scope, at some of the more prominent improvements in medicine, in which our Fellows have taken an active part, will best illustrate the relations of our Society to medical progress.

First, on this continent at least, an ever revered Fellow of our Society, our Preceptor-President, promulgated the fact, that there are diseases self-limited, running their course unabridged, though not modified by medical treatment. Though the pendulum swung to the opposite extreme, and in view of later developments, expectancy was carried too far in the treatment of those diseases, rarely has a greater boon been conferred upon suffering humanity, than by the assertion of the fact, that medicine will not cut them short.

How great a change this assertion wrought in treatment is rather amusingly illustrated by experience in one of those diseases, notably, typhoid fever. Going fresh from the teachings and practice of the senior physician of the Massachusetts General Hospital, whose principal medication in this disease was twenty drops of the spirits of nitrous ether, once in four hours, to country practice, we were early confronted by the opposite methods of an experienced and much respected professional neighbor. His treatment of the same disease consisted in the exhibition of fourteen emetics in daily succession, each one, as was triumphantly asserted, bringing up bile, and yet strange to say, his patient lived.

During our student days the only prerequisites for an examination for a degree in medicine, were that we should bring a certificate of a three years' course of study with some reputable physician and of attendance upon two courses of lectures in a college. The examination was oral, a written thesis only being re-

quired. Some of our physicians devoted themselves to the teaching of students in the interval between the lectures, but there was no organized effort to an association for that purpose until about the year 1840, when two of our then progressive young men met on Winter Street. The one proposed to the other to form a school for the instruction of students during a summer term. The proposition was readily accepted, and the subject being broached to two more of our Fellows, they at once enlisted in the work, and the result was the formation of the Tremont Medical School. Of these gentlemen three ably filled chairs in the Harvard Medical School, while the fourth was one of the founders of our most valuable special charitable institutions and a much beloved and respected physician. This school soon outgrew its original proportions and culminated in the present admirable and ever improving curriculum of Harvard Medical College.

Soon came the discovery of ether. Without going into the question of priority in discovery, many of us may yet remember when Morton first publicly demonstrated that insensibility during a grave and delicate operation could be safely produced. This operation was performed by the senior surgeon of the Massachusetts General Hospital himself, an illustrious pillar of our society, whose far-reaching sagacity comprehended at once the vast results foreshadowed by this first experience.

We are familiar now with its powers, rendering operations feasible which would be impossible without it, assuaging pain of every variety, and if not removing woman's primal curse, so far alleviating it, that rigid believers in ancient theology have even objected to its use in their own hour of tribulation, for that cause alone.

Yet those of us who can remember the cries and moans of surgical sufferers, their pains blunted only by full opiates in cases suitable, as the only anæsthetic available, can best realize what Fellows of our Society have done for humanity, by testing the powers and promoting the use of ether.

Though chloroform was soon after discovered, and our transatlantic brethren, ever jealous of Yankee inventions, vaunted its superiority over ether, its lethal qualities, unaverted by every precaution, soon rendered its use of questionable advantage.

In ophthalmic surgery, its last stronghold, it was attacked by a Fellow of our Society, who demonstrated to the British oculist, that ether was as speedy in action, with proper precaution rarely produced vomiting, rendered the eye as quiescent as did chloroform, with a freedom from danger as is possible in using so powerful an agent.

In preventive medicine, a Fellow of our Society, ever earnest in every benevolent work, after persistent and laborious efforts, induced our State to take the lead in establishing a Board of Health, having demonstrated the vast importance as well as feasibility of removing the causes of disease. Though afterward political chicanery and cowardice destroyed its usefulness for a time, and merged it in a triple monster as unpracticable as it was unwieldy, he has happily lived to see it restored to its pristine simplicity and effectiveness. His name should be blessed throughout the community for his efforts to induce a study of the causes of disease, and to impress upon the public the importance of avoiding them.

In surgical progress a few instances will suffice to indicate what our Society has accomplished.

One of our most illustrious Fellows, distinguished alike for his teaching and achievements in surgery, first threw new light upon injuries of the hip-joint, of inestimable value, especially to the general practitioner, who is not particularly versed in surgery.

Previous to his writings, dislocations of the head of the femur were classified and described clearly enough for diagnosis, and the difficulties in reducing them were well recognized. Our only means for attaining that end was the employment of force, hardly inferior to that which caused the injury. Various appliances had been devised for that purpose, which may well be characterized as the triumph of matter over mind.

It was reserved for him to discover the nature and cause of the obstruction to reduction, and in overcoming it, to substitute intelligent manipulation for brute force.

In impacted fractures of the neck of the femur, which had proved to be amongst the most obscure and intractable injuries, the teachings of the same author, summed up in a paper only too brief, have initiated a new era in diagnosis and treatment. The days of false joints and incurable lameness, with a possible suit-at-law for damages, are passed. The sufferer is now restored to usefulness and comfort by treatment epitomized in the one word, immobility, provided only that be sufficiently prolonged, while the necessary deformity resulting from the injury is practically slight.

The same author inaugurated a new era in vesical surgery, perhaps his crowning achievement. Previous to his researches, the only means of removing a vesical calculus was a dangerous and critical operation which the most experienced surgeon rarely approached without trepidation. Lithotripsy was accepted as hardly less dangerous, and as applicable to but few cases.

The converse now obtains. Our transatlantic brethren, while grudgingly acknowledging priority of suggestion, have made what might almost be termed frantic efforts to improve instruments and methods of operating. But rapid lithotripsy, as originated and perfected by one Fellow of our Society, and frequently and successfully performed by his coadjutors in surgery, stands to-day as one of the most important surgical improvements of our time. Without the possibility of a doubt, the sufferer from vesical calculus owes to a Fellow of our Society the discovery and promulgation of the best and safest means for his relief.

In special medicine, the record of our Society has been one of continued and effective progress.

In ophthalmology, especially, much has been done to preserve the integrity and usefulness of an organ, the loss of which renders life a burden.

Some thirty years ago, the treatment of one of the most painful, and to vision, dangerous, diseases of the eye, was, to say the least, as heroic as it was unsatisfactory. About that time, our senior oculist, whose work and writings have made his name a household word throughout our land, first demonstrated that iritis was amenable to treatment as effective as it is simple, and since that time the disease has lost much of its terrors. It is now daily treated by the general practitioner, to the great comfort of the patient, and with little danger of impairment of vision.

The same author has also demonstrated that another formidable disease of the eye, especially dangerous in infancy, can be effectively arrested without the use of

severe measures. Though his methods may be considered as still *sub judice*, and able oculists maintain the greater safety of the more severe treatment, the fact obtains that patients constantly recover from purulent ophthalmia by the systematic and careful use of mild astringents, combined with the most exact attention to cleanliness.

The efforts of another of our oculists, the son of a pioneer in ophthalmology, and one of the founders of the Eye and Ear Infirmary, to disseminate in the community a knowledge of the frequency and danger of color-blindness, should not be ignored. Though this infirmity, until lately but little known, may not be proven as a common cause of the fearful accidents by land and by sea, with which our daily papers teem, its probability as a misleading agent cannot be too strongly maintained.

In dermatology, our specialists have done much valuable work, the good results of which are by no means confined to their own practice. The general practitioner is now, by their researches, enabled to treat intelligently diseases of the skin which, not long since, were a source of perplexity, while want of success in their treatment, so easily recognized by the sufferers, constituted the opprobrium of the attending physician.

One of the most common of those diseases in general practice, eczema, has been demonstrated to be amenable to the persistent use of gentle remedies. Patients are no longer indiscriminately saturated with arsenic, nor scoured with drastic soaps; and though cases are constantly met with discouraging enough from their persistency, it is rarely necessary for the general practitioner to consign them to the specialists.

In other specialties, in laryngology, in otology, and the rest, similar progress has been made, and it may literally be said, in many an instance, that the blind see, the deaf hear, and the dumb speak, in consequence of the faithful labors of our specialists.

(To be continued.)

### DYSTOCIA CAUSED BY TONIC ANNULAR CONTRACTION OF THE UTERUS.<sup>1</sup>

BY CHARLES F. STRONG, M.D.

Assistant Surgeon Free Hospital for Women, Physician to Out-patients, Massachusetts General Hospital.

FOR the case reported below with its full clinical history, I have selected this title to avoid confusion with cases of the true ring of contraction, which it closely resembles, but from which also it differs in several important particulars, namely: the persistence of the cervix complete and entire throughout the whole labor; the high position of the contraction ring in the uterus, the absence of decided thinning of the uterus below the ring. These points I shall allude to more at length, but state them here for the better understanding of the case.

Mrs. X., primipara, twenty-seven, became pregnant in the latter part of May, 1886, and was under my observation from the following summer until her confinement February 18, 1887. The months of gestation were especially free from the usual troubles, and only during the six weeks immediately preceding con-

<sup>1</sup> Read before the Obstetrical Society of Boston, April 9, 1887.

finement, was it necessary for her to receive attention, first, for extreme constipation (a chronic habit), and second, for neuralgia of the diaphragm and intercostal muscles of the left side. About two weeks before confinement the pain shifted to the right side and remained quite constant although not so severe, for a week, and then disappeared. Early in my examination I palpated the position as occiput left posterior. On Friday, February 18th, I saw her at noon and found irregular pains with a little show had occurred since early morning. The cervix was not taken up nor the os open. She kept about all day, and in the evening the pains became more regular, about every fifteen or twenty minutes but only lasted about a minute. The cervix was very slowly being taken up. Chloral was given with the happiest effect, and a corrosive douche 1-3000.

Saturday, February 19th. Progress was very slow but the patient rested between the pains well, and her general condition was perfect. The pains were fairly strong but short. The cervix was still very distinct, and it was not until 4 p.m., that the os opened enough to admit the finger-tip. At 9 p.m. the os was about the size of a silver quarter-of-dollar. The cervix, very little shortened, pains strong and membranes protruding into the cervix. The head bobbed about above the pelvic brim, showing no inclination to engage. This condition of affairs lasted for several hours, the os, or rather the whole cervix slowly dilating—I say the cervix, because the impression given the examining finger, was of the cervix opening without the previous process of thinning or “taking up.” About this time, too, I noticed a peculiar depression of the anterior abdominal wall, a little more marked during pains, about one-third the distance from the umbilicus to the pubes. It gave to the abdomen much the same contour as an over-distended bladder produces. I knew the bladder had not been neglected, but for certain diagnosis passed the catheter, removing only an ounce or two of urine. As the hours went by, the depression became more marked, but although the idea of a ring of contraction presented itself to me I did not think it would be visible through the abdominal walls of a rather plump patient. Another point that interested me was the high position the uterine tumor retained. The delay in the labor was perfectly accounted for by the posterior position of the occiput aided, it seemed to me, by the presence of an unusual amount of liquor amnii, so at 3 a.m., on February 20th (Sunday), I artificially ruptured the membranes after a vain attempt to induce the head to engage without this procedure. At this time the anterior fontanelle presented, the cervix was the size of a silver dollar, and apparently about as long as normally in the eighth month. Manipulation through the cervical canal was difficult, but I succeeded in flexing the head enough to have it enter the pelvis; attempts at manually stretching the cervix did not advance the progress of the head, and I feared to do much in this way lest I should irritate the muscle into a state of rigidity. A good deal of liquor dribbled away, and after a couple of hours the head came well down into the basin of the pelvis, extended and lying quite transverse. At six o'clock, three hours after rupture, the pains losing all force, I gave the patient two hours rest with ether, and made an attempt to further flex the head, unsuccessfully, there being no resistance from above and the head pressing back into the uterus. At this time I determined a

slight narrowing of the antero-posterior diameter at the brim. The cervix extended in its entire circumference from the pelvic brim well down to the perineum. I saw no reason for interfering, as both maternal and fetal condition was good. Pulse 72 and 126 respectively. At eight o'clock I removed the ether (only a few whiffs were necessary to cause perfect rest). The pains started again, and in force to promise speedy termination, but when the head reached the upper part of the perineum, still pushing before it the elongated, undilated cervix, they again died out, reviving at intervals of twenty minutes, short and weak, nor were they materially aided by external pressure. The head was still extended, despite constant effort at flexion by manual and postural treatment. For the first time active interference seemed demanded, and at 11.30, under ether, the cervix was dilated and forceps applied. There was considerable difficulty in locking the blades, but when once in place the exercise of sufficient force to drag the patient along the bed, failed in bringing down the head. I also tried the forceps reversed, with the same result. The difficulty seemed to exist not so much in the disproportion between the size of head and pelvis, as in some elastic force that retained the fetus in the uterus. Removing the forceps I found the head easily repressed and the neck encircled by the cord, which was slipped off without much difficulty. Advancing the hand into the uterus I found the lower segment flaccid and roomy; and tightly surrounding the fetal body just above the pelvis a constricting band of uterine tissue. The band seemed about three-eighths of an inch thick on its lower edge (a very approximate measure). The existence of this ring decided against further trial of forceps, as also did the fact that as soon as the cord was slipped away from the neck it prolapsed and would not stay repressed. The position was as determined before, occiput left posterior. It was not easy to get my hand above the ring, but the anterior position of the fetal abdomen was of some advantage in this manoeuvre. I brought the right foot down to just inside the vulva, but could get it no lower although external manipulation was employed to the head and breech. I could not find the left foot until I followed down the left leg from the groin, because it laid between the upper detached portion of the placenta and the uterine wall, firmly wedged in. Bringing this foot down too, I completed the version rapidly, the head slipping by the ring with so distinct a snap that I thought it was the femur breaking. No trouble was experienced with the aftercoming head. Miconium had escaped freely after the first foot had been drawn down, and the child when born, was pallid, showing no signs of life. Dr. F. M. Briggs, who was assisting me, at once took charge of the child, female, six and one-half pounds, and after hard work resuscitated her. Attempts to express the placenta failed, and I was compelled to peel it from the uterus over a space about half-a-hand-breadth at its lower edge; all the rest of the placenta was free. The uterus contracted well, except on the right (on which side the placenta was attached). There was no hemorrhage nor any perineal tear.

The history of convalescence was uneventful. At no time was the temperature above normal, 99°. The peculiar uncontracted condition of the uterus on the right persisted until the fifth day, and then the normal oval shape was assumed. The baby had a bloody va-

ginal discharge from the second to the sixth day, at times quite profuse. A thorough examination of the patient at the end of the fourth week showed no laceration of the cervix or perineum, and an involuted uterus. The antiseptic precautions used were those suggested by Dr. Wm. L. Richardson in his paper before this Society, and included a thorough washing out of the uterus at the close of all the intra-uterine manipulations with a hot corrosive sublimate solution, 1-2000, followed by a douche of boiled water.

The points that clinically renders this case of especial value, and in which it differs from any other that I have found recorded, is the evident persistence of the cervix as an independent portion of the uterus throughout labor. The ring of contraction in this case certainly could not have been formed from the os internum, because the cervix dilated *en bloc*, as it were, never thinning out or retracting. Also, there was not, as is usually noted, a prominent caput succedaneum, but the head showed rather the absence of a strong propelling force, and this is entirely in accord with the condition as I found it under ether, that is, paralysis of the muscular structures below the ring of contraction, so that, even during a pain, the cervix could be readily stretched, and the lower portion of the uterus exerted no pressure upon the head, which, above the ring, was firmly grasped; nor did the walls mould themselves closely about the fetus, that is, the only expulsive force was in the small portion of the uterus which lay above the ring of contraction.

I did not recognize that marked attenuation of the lower uterine segment, which must have existed had this annular contraction been the usual ring of contraction, formed by shortening and thickening of the longitudinal fibres. Another point that impressed itself upon me was that, at the end of a pain, the head, even after it had entered the pelvis, receded as though snapped back by an *elastic force*, and the uterus immediately resumed its high position. In fact, I could observe no descent of the fundus during the labor. The abdominal depression has often been observed, but this fact, as a fact, had slipped from my memory, so I did not, perhaps, assign to it its proper diagnostic value.

I have ventured to separate from the mass of clinical details these especial points, and so isolate them into prominence, for I believe them to be in a measure diagnostic of a most dangerous complication of labor. The more dangerous because the fatal termination comes suddenly, with no warning, and where all seems well, except that progress is slow. I think, in this case, my patient was in danger perhaps several hours, while I, feeling that ineffectual pains, the usual accompaniment of a posterior position, had wearied the uterus, waited until after a good rest, strong expulsive pains should start up and terminate the labor. I interfered finally, not from any sign of exhaustion, maternal or fetal, but because the head having partially engaged, and making no advance, I wished to avoid too long-continued pressure. Perhaps, in another case, if the labor were tedious, I should sooner introduce my hand for exploration, but I cannot see at what time I could have been certain that I was dealing with a worse complication than inertia uteri and a posterior position of the occiput.

With regard to treatment, I propose to say but one word. There is the choice between forceps, version, or laparotomy, for I cannot think that a case of tonic annular contraction can terminate favorably, unaided.

I differ, perhaps, from most in that I should make a decided effort to employ the forceps before resorting to version, unless I found a decidedly narrow pelvis or a rigid cervix, either of which conditions, by increasing the resistance, would favor rupture of the uterus. I should elect forceps because it appears that it must be easier to drag the fetal body through the constricting ring than to double that same body upon itself, and thus force it through by version. In performing version, bring both feet down before attempting to turn, otherwise a foot or knee hitching above the ring may defeat all efforts. The question as to the limits within which version is safe must be decided in each individual case. In the case reported, the lower portion of the uterus not being as thinned as in those cases where it is formed from the dilated cervical portion, I think version was a fairly safe procedure; but in the thin, paper-walled uterus of the true ring of contraction, if a gentle attempt at version fails, I decidedly favor Caesarian section.

#### A FEW STATISTICS ON THE COMPARATIVE FREQUENCY OF THE CHANCROID.<sup>1</sup>

BY F. B. GREENOUGH, M.D.

THE portrait of the chancre, as given by the textbooks, is certainly clear, concise, and clean cut, such as would lead one to suppose that there would be no difficulty in recognizing a typical case of this lesion. An ulcer, starting as a pustule, appearing always in a few days, as the result of contagion from a similar one, having decided and well-marked characteristics as to its base and edges, with a tendency to affect the lymphatic glands in its vicinity, and capable, in its turn, of reproducing itself by contagion, is certainly very different from any other cutaneous lesion.

In spite of this individuality, the very different results given by the statistics of different observers as to its comparative frequency, would seem to show that they cannot have used the same rules in their classification of venereal lesions. Through all this diversity of statistics, however, a pretty constant regularity is to be found in two directions: first, that since the time following the period, which Bumstead has so appropriately called that of confusion, in venereal disease, when the chancre began to be accepted as distinct from the true syphilitic chancre, there has been a steady diminution in its comparative frequency; and second, that it is found to occur much oftener in hospital or public practice than in private; in other words, that the lower classes are more subject to its contagion than the upper ones.

A marked exception to the first statement is, however, noted and exhaustively treated of by Mauriac, when, at two different periods, in 1870 and 1871, the chancre increased in a most extraordinary manner for a time in Paris. The early statistics on this subject give, out of 341 venereal ulcers observed at the Midi, 215 chancreids, in a period of three months. M. Puche collated all cases at the same hospital from 1840 to 1850, getting a total of 10,000, the ratio being nearly 4 to 1 in favor of the chancreids, that is, 8,045 to 1,955. These figures are taken from an early edition of Bumstead's admirable work, in which it is also stated that the French observers have found that

<sup>1</sup> Read before the Association of Genito-Urinary Surgeons, at its first annual meeting, May 17 and 18, 1887.

in private practice this ratio is reversed, that is, that the true syphilitic chancre occurs more frequently than the chancreoid. In a table drawn up by Fournier, the proportion given is: chancreoids, 82; syphilitic chancres, 252; ratio, one-third. Fournier's explanation of this difference is that men of the lower classes frequent old prostitutes, who, being syphilized, are protected from another attack, whereas they are liable to an indefinite number of chancreoid contagions.

This explanation would be perfectly satisfactory were the primary lesion the only source of syphilitic contagion in a woman, but inasmuch as the secondary manifestations, such as mucous patches, broken-down papules, etc., are equally so, it is hardly conclusive.

From my own experience, and judging from the comparatively few cases in which I have been able to examine a suspected woman, I should say that the cases where a man was infected from a primary lesion were very rare, and that in the great majority of cases the source of the contagion was some constitutional manifestation, of the existence of which the woman often was unaware. That this difference in ratio exists between hospital and private practice is shown by several of the best French syphilographers' statistics. Is it not possible that many cases may apply for treatment as out-patients on the first appearance of a venereal sore, which looks like a chancreoid, and is entered on the books as such, but which, if kept sight of and watched, as would be the case in private practice, would be found, in the course of time, to develop induration, inguinal reaction, etc., and turn out to be a case of syphilitic infection? That a large proportion of the cases from which the statistics are derived in Paris are only seen as out-patients, is shown by Mauriac's tabulation of his cases at the Midi, during the year 1880, from which it appears that, out of 969 cases of chancreoid without buboes which were seen, 80 were admitted into the hospital, and 889 were "consultants." To return to the comparative frequency, it can be said that all the earlier statistics give to the chancreoid a very decided preponderance numerically over the true chancre, Bassereau placing the proportion during 1837-1838, in Ricord's service, as high as 30 to 1. Later observers have universally noted a change in this respect. The edition of Bumstead and Taylor of 1879, which gives a very complete *résumé* of the literature of the subject up to that date, gives the ratio of the chancreoid to the true chancre, during the years 1869 and 1870, as nearly two of the latter to one of the former.

Mauriac, in his "Maladies Vénériennes," 1883, treats this subject most thoroughly, and, without going into details, it may be said that there was a gradual diminution in the frequency of cases of chancreoid, relatively to those of the true chancre, up to 1870-71, during which year the ratio of 3 to 1 was reached. From 1871 to 1875, the relative frequency of the chancreoid decreased, its ratio being in that year as low as 1 to 10. This ratio increased again from that period up to 1880, when it was a little over  $1\frac{1}{2}$  to 1. These two rises in the ratio, that is, in 1870-71, and after 1875, are considered by Mauriac to be due—the first to the Franco-German War, the Commune, and sieges of Paris, and the consequent license; and the second to the great influx of workmen to prepare for, and strangers to visit, the Exposition in 1878. His explanation of the steady tendency of the ratio to decline when no such disturbing factors exist, will be re-

ferred to later. The first series of statistics of my own that I have to give are, in certain respects, very unsatisfactory. They are taken from the case-books of my service in the Department for Skin and Venereal Diseases at the Boston Dispensary, starting from July 1, 1873. Having carried them up to March 1st of the present year, they cover a period of thirteen years and nine months. The entries in the books give the name, age, sex, residence, and diagnosis of the case on the date of the patient's first applying for treatment. Future developments are not recorded, as a rule, although there is a space of about two inches on one line, under the heading of "Remarks," which can be utilized in any case which is especially interesting or important.

The system of classification which I have adopted for lesions supposed to be the result of venereal contagion, is to enter as chancreoids those cases which show typical chancreoid character, and as primary lesions, or indurated chancre, those that evidently belong in that category. The quite large number of cases, which, when first seen, are doubtful in their nature, are entered as chancres. Besides these three classes, my records show that a certain number of patients came for advice, supposing that they had contracted venereal disease, who had herpes progenitalis. These Dispensary statistics, therefore, will not give the proportion of cases of chancreoid to those of true chancre seen, but will show that out of so many cases of venereal sores, a certain number were chancreoids. Inasmuch as a case would be put down in the doubtful class, because there was something about it which pointed to the possibility of its turning out to be a true chancre, the chances are that the great majority of these doubtful cases did, in time, develop into such, and I am convinced that such has been the case, but it is only a conviction, not backed up by evidence. Again, some of the cases entered as chancreoids, later developed induration, inguinal adenopathy, and were followed by secondary symptoms. The ratio, as given by my table, between the chancreoid and other lesions, is probably not very different from what it would be between the chancreoid and true chancre, had it been possible to follow up each case until its character was pronounced.

CASES OF VENEREAL SORES SEEN AT THE BOSTON DISPENSARY, FROM JULY 1, 1873, TO MARCH 31, 1887. SERVICE OF F. B. GREENOUGH, M.D.

YEAR.	Chancreoids	Doubtful	Indurated Chancre	Herpes Pro- genitalis	Total	Ratio of Chancreoids to total
1st. July 1, 1873 to June 30, 1874	7	41	3	5	56	1:8
2d. July 1, 1874 to June 30, 1875	11	48	5	0	64	1:1.6
3d. July 1, 1875 to June 30, 1876	2	49	8	0	59	1:28

14th. July 1, 1886 to March 31, 1887	25	83	19	2	99	1:4
Total	391	951	219	52	1593	1:4

The absence of something corresponding to my

"doubtful" column in the French hospital statistics, seems to me to detract somewhat from their value, as there are certainly many cases, which when first seen, no diagnostician, however skillful he may be, can determine the nature of with certainty. A consideration of the preceding tabulation shows, that while there are some irregularities in it, notably in the third year, where a most extraordinary and inexplicable divergence is found, there exists a fairly constant ratio, the frequency of the chancreoid rather diminishing during the last four years, and in all of them being less than that given by the earlier statisticians.

The second set of statistics which follow, while much less, numerically, are more reliable and consequently more important. They are collated from a hundred cases that have consulted me in private practice, for venereal lesions, or lesions supposed to be venereal following exposure. In these cases the diagnosis was not made at the first visit, but has been taken from the case-books as resulting from a continued observation of the patients. The cases have not been selected, but have been taken by going back from the present time until a hundred were obtained. Even under these favorable circumstances I have found it necessary to have a column for doubtful diagnoses. It is of course a very much smaller number than come under this head, than in the Dispensary practice, but nevertheless there are certain patients, some of which I saw only once in consultation, at which time the diagnosis was doubtful, and others of whom I lost sight before the true character of the lesion could be definitely settled. The following is the tabulation of 100 cases seen in private practice.

Chancreoid	10
True Chancres	63
Doubtful	13
Herpes Progenitalis	14
Total	100

Ratio of chancreoids to total lesions  $\frac{1}{10}$ .

Ratio of the chancreoid to the true chancre, a little less than  $\frac{1}{5}$ .

These statistics therefore agree with those of other observers both as far as showing that the chancreoid is less frequent in hospital or dispensary practice, than in private, and that it is very decidedly less seldom seen at the present time than formerly. What the cause for this falling off in its comparative frequency is, is a very interesting question, on which I have a few suggestions to offer. Mauriac, who devotes several chapters to the discussion of this subject, gives reasons, which with one exception, which will be referred to later, are strictly local. Briefly stated these are: the more perfect police regulations regarding the tolerated houses of prostitution and registered prostitutes, and the great improvements that have been made in the general sanitary and hygienic condition of Paris. He refers to the fact that a chancreoid in a woman is apt to be a more decided lesion, and more easily seen on examination than some of the syphilitic lesions which would be contagious. This fact is of some importance with us, as although we have no system of inspection of public women, one can easily conceive that that class of prostitutes who depend upon the men of good social position for their living, would not be likely to infect a patron knowingly, whereas they might conceivably give him syphilis from some relapse of which they themselves were entirely ignorant. In 1876, I read a paper before the Boston Society for Medical

Improvement "On the Treatment of the Chancreoid," the main object of which was to protest against what at that time, was universally laid down in the text-books as the proper treatment for the chancreoid, destructive cauterization, which was, however, even then, by no means invariably practiced. The reasons advanced were briefly, the painfulness of the treatment, the almost certainty of producing an inflammatory phymosis in cases where the prepuce was long, the masking of the diagnosis by setting up a pseudo induration of inflammatory origin, the likelihood of starting a suppurating inguinal adenitis, and last, but most important, the fact that the lesion did better when treated in a milder way. The ten years and more that have elapsed since then have only confirmed me in the correctness of the views advanced, and I have not since then once used cauterization in the treatment of a chancreoid. It may not be apparent what connection there is between the treatment and the frequency of this lesion, but if I am correct in assuming that destructive cauterization is worse than useless, the older syphilographers were entirely mistaken, and such men as Ricord, Diday and Clerc went on for years needlessly putting their patients to great pain, unless there has since their time been some change in the character or type of the disease. And such I believe must be the case. In the paper which I have referred to, which appeared in the *Boston Medical and Surgical Journal*,<sup>2</sup> I made the statement, that in my opinion, besides being less commonly met with in practice than formerly, we did not see such severe cases of chancreoid, one destroying much tissue, and resulting in a deforming cicatrix, being very rare. Of the correctness of this statement also, I am still further convinced, not having seen since that time a single case where decided loss of tissue resulted from a sore, which came under my observation in an active state. I have no doubt but what, if I visited Deer Island or Tewksbury, or the Chelsea Marine or Naval Hospitals, I could see such, but I believe many fewer than twenty to thirty years ago. It was with much pleasure that I came across the following statement by Mauriac, which I translate. After describing the serious result of phagedenic action on chancreoids in the past, he says,<sup>3</sup> "Phagedenism which so frequently formerly interfered with the cure of chancreoids, which made them very serious and even disastrous affections, has become an entirely exceptional phenomenon. We scarcely see two or three cases yearly in our service, and even those are of a benign character, and are not difficult to control."

That a disease may in the course of time become modified as to its severity, is, I think, shown in the case of syphilis, as far as its manifestations on the skin go. We certainly see fewer of the ulcerative syphilides in proportion to the number of cases treated at the present time, than were seen twenty or thirty years ago, judging from the literature on the subject, and also from the cicatrices seen in old cases. That this difference is in a great measure due to the improved treatment, I have no doubt, but we do see certain cases where through ignorance, or recklessness, practically no treatment at all has been taken, and yet the patients never have any relapse either in themselves or offspring. It must, however, be said that while the large majority of cases of syphilis are com-

<sup>1</sup> Vol. xcvi. January 11, 1877, No. 2.

<sup>2</sup> Leçons sur les Maladies Vénériennes, Paris, 1883.

paratively benign, the lesions of the nervous system are much more frequent than formerly, especially during the early stages of the disease. We must either admit that these nervous lesions have increased in frequency, or else assume that the older writers did not recognize them, and it hardly seems possible to suppose that such close observers could see young patients showing cerebral or spinal symptoms, during an attack of syphilis, as often as we do, without connecting the two together. Apart from the question of possibility of change in type in the chancreoid, what other reasons are there for its less frequent occurrence? The extreme predominance numerically, given to it in the earliest statistics, might be perhaps explained by the fact that it had just been discovered, so to speak, and that Riord's and Bassereau's writings called attention to the fact that there was such a lesion as a local, non-syphilitic sore, and consequently everybody was anxious to avail themselves of the new doctrine. In other words, for a certain time, chancreoids were the fashion in the medical world, and very possibly every lesion that did not show marked induration and glandular enlargement in both groins, was recorded as such. Inasmuch as the earlier syphilographers make no mention of herpes progenitalis, and as their treatment was to cauterize all suspected lesions following exposure, it is more than probable that at that time, many crops of herpetic efflorescences may have been diagnosed as chancreoids. There is another, not very uncommon lesion, which may have been mistaken for a chancreoid, as is not unfrequently done at the present time. I refer to an inflamed sebaceous follicle, on the shaft of the penis, which begins as a pustule with an inflammatory areola, and which when the pustule is destroyed leaves a circular, punched-out looking ulcer, which will only require one or two applications of some strong caustic to make it a very good copy of a chancreoid.

There can be no stronger proof that some modification must have taken place in the chancreoid, a lesion which as described, is one most essentially *sui generis*, than the fact that some of our most distinguished syphilographers have gone so far as to deny its individuality, or at least to claim, that a lesion which is identical with it, may result from immediate contagion from, or artificial inoculation with, any pus resulting from inflammatory action.

That pus inoculated will produce a pustule, has been proved, but that healthy, non-septic pus brought in contact with the cutis or a mucous membrane can cause an ulcer resembling the chancreoid, has not, at least in my opinion. When we think of the enormous number of cases where inflammatory pus is brought in contact with the skin of the patient suffering from the inflammation, as in cases of amputation, operations for tumors, abscesses, in short, all surgical operations that do not heal by first intention, in which nothing like a chancreoid is found, and then remember what every practitioner who sees venereal disease must have observed, namely, cases where somewhere in a circular line, drawn on the lower abdomen and inner part of the thighs, a circle of which the penis is the radius, a chancreoid is seen as the result of auto-inoculation from chancreoidal pus flowing from the orifice of the prepuce, we must admit that the chancreoid is a fact, even if not as frequently seen as formerly.

There is one form of venereal lesion of which I have seen a great many examples, to which I

want to refer in this connection, and that is what has been very thoroughly described as the *ulcus exulcerans*, or *elevatum*. The reason that I do refer to it, is, that I have often been in doubt as to its nature, that is, as to whether it belonged to the chancreoids, or true chancres, and have thought that it suggested the "mixed chancre" of Diday. The lesions I refer to are always multiple, situated on the free margin of a long prepuce, suggesting inoculation from a sub-preputial sore, or auto-inoculation from each other, or both. They are not larger, as a rule, than a small pea, raised above the niveau, ulcerated on their summit; with the base of the ulceration like that of a chancreoid. They usually are situated in a fold or wrinkle of the free margin of the prepuce, which fold when the prepuce is retracted as far as the usually accompanying phymosis will allow, is reproduced in the lesion as a split. They do not show any marked induration, but evidence of an indurated sore is apt to be obtained under the prepuce. They are always most obstinate against treatment, although they do not show any decided tendency to increase in size. They almost invariably are followed by secondary symptoms. In the few cases in which I have experimentally used specific constitutional treatment, the duration of the lesion has been somewhat, but not markedly shortened.

In cases where we get evidence of an indurated chancre under the prepuce, of course the consequent secondary symptoms are explained, but what is the nature of the raised lesions at the preputial orifice? Their situation is exactly that which would suggest auto-inoculation, namely, in the folds where the sub-preputial secretions would be retained, and also their position with regard to each other is very suggestive, as they are very apt to be found in pairs which come together in exact apposition. Their situation at the preputial orifice also would suggest the possibility of the daily irritation during the act of micturition, having something to do with their obstinacy against treatment, and also, perhaps, having some influence on their peculiar raised character. Certainly I have never seen typical specimens of the lesion I refer to, except in this locality, although something like them is seen at times as a single lesion, in the sulcus, or on the reflected prepuce. I must confess that I have at times in these cases been tempted to make an exception, and try the use of destructive cauterization, but the fact that an already troublesome inflammatory phymosis would be decidedly aggravated, has deterred me from so doing.

There is one other respect in which I think the chancreoid of the present day differs from that of the past, and that is in its being complicated by a suppurating, or virulent bubo. I will not take time to go into statistics of the past, as I have none of my own to offer, except to quote from Rollet's service at Lyons, where out of 140 cases, 60, or 1 to 2, had virulent buboes. The fact, however, that chancreoids were liable to have this complication, has been universally admitted, in fact it has been made one of the important diagnostic points. Without having any evidence to fall back upon, I should say that in my experience virulent adenitis was not more frequently seen with the chancreoid, than with the true chancre, and I cannot help thinking that this is due in a measure to the fact that irritating the lesion by caustics is at the present time not usually practised. This is, of course, only my opinion, but I have seen some cases

where an acute adenitis followed at once on the use of caustics.

There are, of course, many points of interest with regard to this subject that I have not even touched; all I have attempted to do has been to lay before you some statistics which I had, with a few suggestions resulting from my observation of the cases. These statistics would go to show, what others on the same subject do, that the chancre is decidedly less frequent at present, than it was formerly; and in addition to the reasons I have given that may have had an influence on that change, I must say, in conclusion, that I believe chancroids are less frequent because we have in a great measure ceased manufacturing them, by cauterizing every sore that is not a typical primary lesion.

#### ABSCESS OF THE KIDNEY FROM OBSTRUCTION TO A URETER.<sup>1</sup>

BY JOHN G. BLAKE, M.D.  
*Visiting Physician, Boston City Hospital.*

MR. B. S., thirty-five years old, first came under treatment five years ago for irritation of the bladder, and symptoms suggesting stone. Pain in the region of the left kidney was constant, but not of such a severe character as to draw attention away from the bladder, which seemed to be the seat of the severest pain. The urine, at this time, was examined frequently, and showed the ordinary conditions found in cystitis: pus, some blood, epithelial scales, and mucus. The treatment was directed chiefly to the bladder, and the existence of a renal abscess was not suspected. In three weeks after beginning the treatment, a quantity of dark-green pus, resembling chewed grass, was found in the vessel, mixed with urine, the quantity of pus being estimated at ten ounces. After a few days, the pain in the side subsided, but the vesical irritation continued without much relief. Permission for an examination under ether was at last obtained, and the bladder carefully sounded, but no stone could be detected. The general condition, however, improved a good deal, and he passed from under my care to resume business.

Six months after I received a note from him, inviting me to call at the Massachusetts General Hospital. He had been again under treatment, and had been examined by Dr. Bigelow, who found a stone, crushed, and removed it. It may here be stated that, three years before this, the patient was attended by a member of this Society, for what proved to be an abscess of the kidney, which ran its course without giving rise to severe constitutional symptoms. At least, this was the patient's statement.

The present attack began February 20, 1887. Since the termination of the illness attending the removal of the stone, Mr. B. had been quite well, and attending to business that necessitated much railroad travel. It was to exposure to cold during one of his frequent trips, that he attributed his last illness. Pain in the side, extending down toward the groin, and resembling that of an attack of gravel, was the first symptom. Local treatment relieved this somewhat, but never wholly. The urine showed no sign of either gravel or pus. Day after day, the pain continued, with a ris-

ing temperature and pulse, and constantly requiring the free use of morphia subcutaneously. On the seventh day he had a chill. There was no doubt about the diagnosis, and the treatment aimed at saving strength and pain until the abscess should evacuate through the ureter and bladder, as it had done twice before. After twelve days, the symptoms began to look more serious, and surgical counsel was sought, with a view to interference, if it were deemed advisable. Dr. Gay examined the case, but decided not to operate, the external evidences of the presence of pus, and the uncertainty of the result making this course, in his opinion, the safest. The favorable termination of the previous attacks justified this conclusion, and held out reasonable hope of a spontaneous cure.

The following day, severe pain, extending toward the nipple, and attended by difficult and gasping breathing, was complained of. It was evident that inflammatory action was progressing upward, and percussion and auscultation gave signs of lung invasion and effusion. From this time, the patient began to sink rapidly. Dr. Cabot saw him next morning, but too late to attempt an operation, even if it had been considered advisable. He died in the afternoon. This is the outline of the case in brief, omitting all details, which are not of necessity. It is reported chiefly for the purpose of bringing before the Society the subject of surgery of the kidney, and the question of operation in cases of like character. It was of special interest to me from the fact that I had, at the same time, two cases of chronic pyelitis under my care at the City Hospital, which did not improve under medical treatment.

As the autopsy showed, there was no possibility of a successful operation in the case. At the same time, the conditions found were of such an unusual character as to be seldom met with. I shall not presume to discuss the surgical aspect, leaving that to others better qualified, but shall be glad to hear the sense of the Society on the general question, as a guide for the future. It may not be out of place to state that the subject of the removal of the kidney was discussed with the patient and his relatives during the early stages of the disease, and would have been agreed to had the present attack terminated favorably. The obstruction of the ureter, found at the autopsy, was suspected as the probable cause of the abscess not emptying, but could not be demonstrated during life. The uncertainty of the duration of the abscess of the kidney before finding an outlet into the surrounding parts, together with the poor success generally attending surgical interference, were considered additional reasons for not operating.

So far as I can learn from conversation with surgeons, the surgical treatment for abscess and kindred affections of the kidney, and the removal of that organ, have not been attended with a degree of success, in this community, which would encourage such methods. Still, these operations have very frequently been performed successfully in other places, and I am not willing to admit that we are wanting either in the skill or the means to obtain equally good results. Larger experience in this, as in other fields, will undoubtedly lead to improved results; and, although the cases are comparatively rare, a sufficient number will come to us to furnish an improvement in statistics, and to stimulate us to more frequent operations.

<sup>1</sup> Read at the Boston Society for Medical Improvement, April 25, 1887.

## RECORD OF AUTOPSY.

by Dr. W. W. Gannett, March 11, 1887, 10.30 A. M.  
Body medium size, well developed, considerably emaciated.

The pericardium contained about 30 cc. slightly cloudy fluid. Both pericardial surfaces covered with a thin, recent, fibrinous false membrane.

The heart showed nothing remarkable as to size, valves, cavities, or muscular substance. The left pleural cavity contained, by estimate, two litres of pus, having a very marked odor of sulphuretted hydrogen. Both pleural surfaces of the left side covered by thick, grayish, shreddy, fibrinous false membranes. The left lung was about the size of the double fist, dense, non-aerated, showing, on section, a dark-red, flesh-like appearance. The right pleural cavity and right lung not remarkable.

Spleen showed nothing unusual.

The urinary tract showed the following appearances: For a distance of one cm. (half-an-inch) above the bladder, the left ureter was of the normal size. Just above this point, was firmly impacted an oblong calculus, about the size of a plum. The ureter, at this point and upwards to the pelvis of the left kidney, was represented by a slightly tortuous tube, three cm. (one-and-one-fourth inches) in diameter. (The ureter, when opened and flattened, measured nine cm. transversely.) This was distended with thin pus. The pelvis of the left kidney was represented by a sac, the size of the fist, distended with thin pus. On section of the left kidney, the calyces were found to be much enlarged, there remaining a layer of renal substance not more than 1.5 cm. in width. The mucosa of calyces showed several grayish-black, circumscribed, shreddy areas, where there was a loss of substance.

In the upper portion of the kidney was a fistulous track, extending from one of the dilated calyces, through the renal substance, to a cavity outside the kidney, to be presently described. The fistula had a diameter of two or three millimeters (one-eighth-inch), the edges being softened, grayish, shreddy, renal tissue. Behind the upper half of the left kidney, occupying the situation of the perinephritic tissue, was a cavity, the size of the fist, with grayish-black, shreddy walls, and filled with a foul-smelling pus. Extending from this cavity upward, through an opening in the cavity, the pus had infiltrated the connective tissue lying to the left of the vertebral column, behind the stomach and pancreas, and reaching the diaphragm. At a point in the diaphragm, a little to the left of the median line, in the posterior third, the tissue was softened, thinned, ragged, with an opening large enough to admit the tip of the little finger. This served as a direct communication between the abscess-cavity below, and the pleural-cavity above.

There was nowhere evidence of peritonitis.

The bladder and right ureter showed no abnormal appearances.

The right kidney was enlarged about one-third, showing, on section, the usual ratio between cortical and pyramidal portions. The renal substance not remarkable.

The gastro-intestinal tract, liver, and aorta showed no appearances worthy of especial note.

**Diagnosis.** Acute fibrinous pericarditis; acute gangrenous pleurisy, with purulent exudation; carnification of left lung; hydro-pyo-nephrosis; circumscribed

necrosis of left kidney, with fistula; calculus in left ureter; dilatation of left ureter; suppurative perinephritis; suppurative inflammation of tissues along vertebral column; circumscribed necrosis of diaphragm, with perforation; compensatory hypertrophy of right kidney.

**Sequence of events, as shown by the autopsy.** Obstruction of left ureter by a calculus, leading to dilatation of ureter above, and pelvis of kidney and calyces, with atrophy of kidney; suppurative process in pelvis of kidney; necrosis of mucosa of calyces and of kidney, leading to perforation of kidney and discharge of pus into perinephritic tissue; perinephritic abscess; extension upwards to diaphragm; perforation of diaphragm; gangrenous pleurisy; death.

## Clinical Memorandum.

## TRANSMISSION OF SCARLATINA BY DISINFECTED CLOTHING.

BY JAMES B. FIELD, M.D., LOWELL, MASS.

On February 3d, Winnie W., aged ten, was taken sick with scarlatina. For many weeks previous there had been no cases of scarlatina in the section of the city in which she resided, and but few cases in the entire city.

On February 5th, 6th, and 8th, three younger sisters were attacked with the disease, taking it, in all probability, from the same source as did Winnie.

The fifth and remaining daughter was severely sick with scarlatina a year ago while in another city. Upon the cessation of desquamation her clothing and that of her mother were thoroughly disinfected, under a physician's direction, by exposure to sulphur fumes and by prolonged boiling.

The trunk containing this clothing arrived in Lowell ten days before Winnie, the patient first mentioned, was taken sick. Upon opening the trunk all the children played with the clothing, dressing up in their mother's and sister's garments.

Although some unrecognized source of contagion is possible, the fact that four children were taken sick with scarlatina at intervals of from ten to fifteen days after exposure to this disinfected clothing, would seem to show that the ordinary methods of disinfection are not always safeguards against contagion.

## Reports of Societies.

## PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. M. GREEN, M.D., SECRETARY.

APRIL 9, 1887, the President, DR. WILLIAM L. RICHARDSON, in the chair.

DR. C. P. STRONG read a paper on

DYSTOCIA CAUSED BY TONIC ANNULAR CONTRACTION OF THE UTERUS.<sup>1</sup>

DR. EDWARD RETNOLDS, present by invitation, asked if a distinction should not be made between the cases in which a spasmodic annular or hour-glass

<sup>1</sup> See page 543 of this number of the Journal.

constriction occurred, and those in which the true contraction ring of Bandl was found. The one being due to an excessive action of the circular fibres in some one zone of the uterus, and, therefore, having necessarily a tendency to clasp the uterine contents as a constricting ring; while the other is formed by the retraction of the upper uterine segment and its consequent excess of thickness over the lower segment, is entirely independent of the circular fibres, and, in its most typical form has no tendency to annular constriction.

DR. GREEN said that normally the fetal head in first pregnancies should descend and occupy the true pelvis in the last week or ten days of gestation. When this descent does not take place, the reason is usually to be found in some pelvic and cranial disproportion, however slight, or in an unfavorable fetal position. When the occiput is posterior the head often fails to descend before labor begins, owing to the fact that the biparietal diameter does not readily pass through that chord of the pelvis which subtends the sacro-iliac arch, this chord being less than either of the oblique diameters through which the biparietal passes in anterior positions. When, therefore, in first labors the head is not found in the pelvis, he believed that the cause of the non-descent should be early sought for and appropriate treatment decided upon before long-continued and futile efforts of the uterus have resulted in a condition of inertia or in the formation of a firm "contraction-ring" with corresponding thinning of the lower uterine segment, which latter condition makes subsequent operative procedures more difficult and dangerous.

When the position of the occiput is anterior, unless the relative disproportion is more than slight, the force of the uterine contractions is usually sufficient to drive the well-flexed head into the pelvis; but in occipito-posterior positions, owing to the reason above alluded to, proper engagement and descent often do not take place: either the head rests on the superior strait in a condition of non-flexion and no progress is made, or the head becomes extended, the brow dips down into the pelvis, giving the appearance of progress, while, however, the larger diameters of the head remain above the brim. In this state of affairs, unless the relative disproportion is more than slight, he would endeavor, with one hand in the vagina and the other on the mother's abdomen, to change the fetus into an anterior position; then, if successful in the manoeuvre, would rupture the membranes, give the uterus time to drive the head into pelvis, and then if necessary deliver with forceps. If, on the other hand, this change of position should prove impossible, or if the pelvic contraction is marked, he would perform podalic version early, while this operation is easy and safe.

If, unfortunately, the case is seen late, after a well-marked "contraction-ring" has formed, version is often a difficult and hazardous operation, and the high forceps operation is scarcely less so: under these circumstances each case must be considered by itself, whether either version or forceps is justifiable, or whether craniotomy should not be performed in the interest of the mother. If the child is dead, the decision of this question is easy.

When after long and futile efforts the uterus has passed into a tonic state and the contraction-ring tightly grasps the fetus, the difficulties and dangers are greatly increased; and it is wise to resort to

surgical anæsthesia, sufficiently prolonged to relax the spasmodic condition of the uterus, before undertaking any operative measure. The speaker's experience with the difficulties of this class of cases had led him to believe strongly in early interference when in primiparae the head had not engaged before the advent of labor, and in multiparae when a few hours of good pains did not drive the head out the pelvis.

DR. EDWARD REYNOLDS reported, by invitation, the following

#### CASE OF PLACENTA PRÆVIA.

I delivered yesterday a case of placenta prævia which may be of interest to the Society.

The patient was a primipara and was within a few days of the expected date of delivery, when on rising from bed at 7 A. M. yesterday she found herself flowing; the hemorrhage lasted some minutes and was described as profuse. Though it left her faint and dizzy, she still kept about on her feet, but fortunately sent at once for medical aid. Her attendant arrived just as she was attacked by a second hemorrhage, in which she lost about 8-10 $\frac{1}{2}$  of blood. He at once put her to bed and the hemorrhage soon stopped, a mere trickle of blood continuing to escape from the vagina.

I was then sent for, and arrived at 9.45 A.M., when her condition was as follows: Labor pains present, weak but regular. Position O. R. A. Fetal heart not heard. Os about the size of a five-cent piece, soft, and completely covered by the placenta, which was implanted to the left, but extended on the right to about an inch beyond the margin of the os. A slight but steady hemorrhage was going on. The pulse, though weak, was only 96, but the lips were blanched, the respiration was quick and sighing, and the patient was restless and uneasy.

As nothing was in readiness for an operation and as she was still losing some blood, I tamponed her while the necessary preparations were being made.

At 10 A.M. she was etherized and the tampon removed; by this time she was noticeably weaker and was jactitating, though, so far as could be seen, no further loss of blood had occurred. The os had enlarged to about the size of a twenty-five-cent piece, and was so soft, that after separating the placenta for about an inch beyond its margin, it was dilated manually in about five minutes, to a size which permitted the passage of the hand. A foot lay just above the os and the child was turned with extreme ease. The separated portion of the placenta was now prolapsed through the cervix and with the half-breech was tightly clasped by it. A finger passed along the child's belly found the cord pulseless (the heart had not been heard) and as all hemorrhage had now ceased, I decided to wait for further dilatation before delivering.

The patient was allowed to recover partly from her ether, and the pains returned. For twenty minutes the pulse was carefully watched and the breech kept closely applied to the lower uterine segment by gentle steady traction on the foot. Then the os having become fully dilated, the ether was again carried to surgical anæsthesia, and a female child was slowly extracted. No hemorrhage followed, but though the uterus was very firmly contracted, efforts at expression by Crêde's method failed to dislodge the placenta, though steadily persisted in for five minutes, when, fearing that hemorrhage might occur, I introduced

the hand and was surprised to find that the upper part of the placenta was so firmly adherent that it was separated with great difficulty, several pieces tearing away and rendering it necessary to re-introduce the hand several times before the last shreds could be detached. About one-third of the placenta was detached, one-third normal, and one-third adherent.

During delivery the pulse never exceeded 120, there was no post-partum hæmorrhage, and on recovery from the ether it fell to 104. Half an hour later it was unchanged, and I left the woman conscious and in very fair condition. All went well for two hours, when a severe collapse occurred and I was again called. For some minutes the pulse had been very rapid and almost imperceptible, but the uterus had never relaxed, no hæmorrhage had taken place, and a reaction had set in before my arrival. Under the free use of stimulants she rapidly improved, and when I last saw her, an hour ago, was in very good condition.<sup>2</sup>

In the management of the case, the policy of version through an imperfectly dilated os, and subsequent slow extraction was chosen, because, as the child was dead, and the mother so much exhausted that any further loss of blood, whether ante-partum or post-partum and however slight, was of grave importance; it seemed to be the wisest course to turn at the earliest possible moment, without attempting complete dilatation, and then to delay long enough to permit dilatation and retraction to occur naturally before emptying the uterus; in the fear that rapid evacuation might bring on a perhaps fatal post-partum hæmorrhage or collapse.

DR. SINCLAIR said he disbelieved in emptying any uterus too rapidly: there was less likely to be post-partum hæmorrhage by delivering slowly.

DR. E. REYNOLDS said that he adopted this policy of slow extraction after version; first, because it has been highly recommended by high authorities in Germany for all serious cases of placenta prævia, even during the life of the child; and, secondly, because both the dicta of authority and his own observations have led him to believe that rapid evacuation of the uterus, not only favors post-partum hæmorrhage, but is in itself an efficient cause of immediate surgical shock, and that it was therefore a thing to be avoided in a case where the child was dead and the mother already much collapsed, provided that the danger of further ante-partum hæmorrhage was carefully guarded against by steady, gentle traction upon the foot, and by keeping a close watch upon the pulse. The result was certainly most happy in this case.

— A free dispensary has been established in a central location at Newport, R. I., through the efforts of the Guild of St. Luke, a society of medical gentlemen and clergymen, founded about a year ago.

— The uncomfortable habit which prevails in some half-civilized countries of making the doctor swallow his own medicine, to prove that it is innocuous, received a most tragic illustration recently in the Argentine Republic, where a physician was murdered by peasants because he refused to drink from a bottle of carbolic acid, which he used for purposes of disinfection.

<sup>2</sup>The further history of the case has been that of rapid and complete recovery.

# BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

APRIL 25, 1887. The President, DR. O. F. WADSWORTH, in the chair.

DR. JOHN G. BLAKE read a paper upon

ABSCESS OF THE KIDNEY FROM OBSTRUCTION TO A URETER,<sup>1</sup>

and showed the specimen from the case upon which it was based.

DR. A. T. CABOT said that the position of the calculus so deep in the pelvis, and its firm impaction in the ureter, would have made its removal through a lumbar incision practically impossible, even could it have been detected.

Possibly earlier in the history of the case it would have been found nearer the pelvis of the kidney, and might then have been successfully removed. It also could not have been reached from the side of the bladder. The speaker had operated on three cases of obstructed ureter. The first patient was a boy with hydronephrosis in which the sac was drained, and he got entirely well.

The second was a young man with long-standing disease of the urinary tract, whose urine contained a large quantity of pus. One kidney swelled up, and an opening was made into what was thought to be the pelvis, and considerable pus was evacuated, with some relief. He lived some months, and when he finally died an examination showed that the cavity which had been drained was a tuberculous abscess of the cortex of the kidney.

The third patient was a young woman with a tumor in the left side of the abdomen, which could be moved from the edge of the pelvis to beneath the ribs. Her urine contained pus intermittently, and the diagnosis of pyonephrosis of a movable kidney was made.

An incision was made in the loin, the kidney was secured to the edges of the wound and then incised; a considerable quantity of pus being evacuated. The cavity steadily closed and the amount of pus diminished until it almost wholly ceased. The opening had so nearly closed that a probe would only enter for half an inch, and she was allowed to leave the hospital, but soon returned with a fresh access of inflammation, the result apparently of want of cleanliness. The sinus after this did not show any tendency to heal.

Several months later she was again seen with commencing Pott's disease for which a brace was fitted. When last seen she was looking well, but the sinus was still discharging.

The appearance of spinal caries in this case suggested the idea that the kidney might also be tuberculous.

DR. E. S. WOOD said that it is by no means uncommon for the pain of pyelitis to be referred to the bladder.

DR. JOHN HOMANS said that his experience in operations upon the kidneys has been limited and fatal. He then proceeded to give the history of his cases. One was a feeble woman who had been suffering for six or seven years from a renal abscess. An incision was made into the abscess, anteriorly through the peritoneum, several calculi were removed and the wound was drained. She improved for a time but finally died. No autopsy was allowed.

<sup>1</sup> See page 549 of the Journal.

His next case was a renal tumor which was sometimes small and sometimes large, according as pus was present in the wound in large quantities, or was absent. He was at first unable to make a diagnosis, and as the patient did not get better, sent her to the Massachusetts General Hospital, where he cut down in the loin upon the kidney, giving exit to a pint or more of green pus mixed with much mucous. The patient was taken home by her friends in a few days, thereby hastening the fatal result, which was probably inevitable.

Another case was one of very painful cystitis and pyelitis, sent to him by Dr. Baker, who had previously opened the floor of the bladder without much benefit. Pus evidently existed in the right kidney, and Dr. Homans incised and drained it, with much relief. There were no calculi. Death followed in four or five months.

He had extirpated a sarcomatous kidney, but suppression of urine occurred in the other kidney, and the patient died in forty-eight hours, not having secreted more than an ounce of urine after the operation. Another large suppurating kidney, supposed to be sarcomatous, he had also removed. This case was likewise followed by suppression of urine and death.

DR. E. H. BRADFORD said that he had had but little experience in the surgery of the kidney. He had operated upon a child with hydronephrosis, in which case an exact diagnosis had not been made. There was a cyst of the kidney or of the kidney and ureter. He had made an incision into the cavity and washed it out. The wound healed without suppuration. He had also operated twice upon adults. The first case was of surgical interest. There was a tubercular abscess of the kidney in a man of thirty-five. This was incised without difficulty and the symptoms were relieved, but the patient died in a few weeks. He had had hip disease as a child, but had recovered. Autopsy showed acetabular disease and an abscess cavity, but the pelvis had apparently recovered. A large indurated mass extended from the acetabulum to near the kidney. The kidney was tuberculous with the tissues about it inflamed. The peritoneum was also inflamed.

The other case was somewhat like one of those of Dr. Homans. He had drained the bladder and afterward opened the kidney. The patient died in four months.

There had been a few other cases at the City Hospital. Dr. Burrell had operated successfully for a calculus in the pelvis of the kidney. The calculus was not found, but the patient recovered. Dr. Gay had also some cases, but of these the speaker did not remember the particulars.

In New York these operations had been quite fatal in the last five years, but if the statistics for a longer time were selected they would probably be better. The English and German results are very encouraging.

DR. R. H. FITZ remarked that the history of the case indicated a pyonephrosis secondary to a hydronephrosis. It seemed probable that the evacuation of the pus, several years ago, was due to the passage of a calculus into the bladder, and not to the rupture of a renal abscess into the pelvis or ureter. The vesical calculus subsequently crushed was likely to have been this dislodged stone.

The final attacks of suppurative inflammation apparently occurred in the urinary tract which had become

gradually dilated to so unusual an extent by a second, obstructing calculus. The communication between the pleural cavity and the dilated renal pelvis was one of the results to be anticipated in the course of a pyonephrosis. Though less frequent than the formations of fistula opening into the intestine, it was, perhaps, more to be feared.

The results of the post-mortem examination suggested that a lumbar incision, with the establishment of drainage, would have obviated the impending danger, although it might not have permitted the extraction of the calculus. The position of the latter indicated the importance of a rectal examination in all cases of suspected abscess of the kidney, although the results of such an examination would usually prove negative.

DR. HAMILTON OSGOOD asked that some surgeon present would be kind enough to say whether there exist reasons against the removal of a suppurating kidney, which do not hold in cases of cancerous kidney; and whether locality or climate have any presumable connection with fatality in surgery of the kidney? The questions, he said, were suggested by the admirable results in a case which he saw at the hands of Krönlein in Zürich, who removed a sarcomatous kidney from a woman. Six weeks after the operation the patient was in robust health.

DR. BRADFORD said that as no one else seemed inclined to answer Dr. Osgood's question, he would say that he thought the reason for a larger percentage of successes in other places, is the fact of a greater number of operations. When one has operated sufficiently often he expects to get some successes.

DR. HOMANS said that it is a dangerous thing to assume that a difference of climate makes a difference in successes. The difference is in operators, in knowledge, skill, and care. If any one can remove the kidney without failures he is willing to own that he is a better surgeon than is Dr. Homans. He does, however, believe that some foreigners have a stolidity not found in Americans, which enables them to bear severe operations. To Dr. Osgood's other question, he said that he believed that the statistics were rather more favorable for the removal of a suppurating than for that of a cancerous kidney.

DR. CABOT said that a non-suppurating kidney is more easily removed, that a kidney that has been first drained is more easily removed at a second operation; that is, that a small thick wall is more easily and safely taken out than a large thin one. It is not so likely to rupture.

DR. OSGOOD remarked that it was only fairness to American surgeons and their material, to say that there does indeed exist a wide difference between Americans and Germans, at any rate, in physical stolidity.

For example, he saw Czerny of Heidelberg, amputate nearly one-third of the stomach at the pyloric extremity. Four days later, the patient, a man, was quite cheerful, was drinking his wine, and Czerny seemed very hopeful about the case.

In Schwalbach, in particular, Dr. Osgood had observed remarkable differences between American and German women. The latter were able to drink their five to eight full glasses daily of the Weinbrunnen water, which is very strong in iron and carbonic-acid gas, while the American women, who were under his care, could not safely drink more than one-third of this amount.

The same peculiar difference was seen in their respective ability to endure baths — the German women remaining in the powerful water fifteen to thirty minutes. If the Americans took baths of more than six to eight minutes in duration, flushing of the face and intense headache with functional disturbance of the heart were the result.

American women who have frequently been abroad learn that it is wiser for them, in case of need, to consult an American, or English, rather than a German physician, finding themselves unable to cope with medical treatment which German women bear with impunity. The difference probably lies in a far more sensitive nerve-tissue on the part of the Americans.

#### DRAINAGE OF ABDOMEN IN TUBERCULAR PERITONITIS.

DR. HOMANS mentioned a case of supposed ovarian disease in which on opening the abdomen, the peritoneal cavity proved to be filled with fluid and the peritoneum itself, studded with tubercle, as was shown by the microscope, a piece being removed for the purpose. The fluid was removed and the wound closed. The patient made a good recovery, after long drainage (eight months) and is now fat and healthy. Another case, supposed to be ovarian cyst, or a cyst of the broad ligament in a seemingly healthy girl of seventeen, who had a fat abdomen, proved to be tubercular peritonitis, with ascites. One Fallopian tube and one ovary which were thickened, were removed, together with bloody serum. The peritoneum was dried as thoroughly as possible, and a glass drainage-tube introduced. The patient recovered and now looks well.

DR. HENRY I. BOWDITCH said that the two cases of tubercular peritonitis related by Dr. Homans, in which improvement took place after laparotomy and antiseptic washing of the peritoneum, reminded him of a similar case related to him by the operator only a few days ago. When the peritoneum was opened it was found studded with miliary granulating tubercles. The microscope revealed the presence of numerous bacilli in a small piece taken for examination. The patient now calls herself well, and has gained several pounds of flesh, and is travelling in Europe.

A question Dr. Bowditch would ask, under the light of these three cases, is whether modern antiseptic abdominal surgery may not ere long decide that in cases of so-called tubercular peritonitis in childhood, hitherto deemed incurable, laparotomy and antiseptic washing of the peritoneum must be performed, or the physician will fail of his duty.

DR. CABOT referred to a case of tubercular peritonitis in a colored girl of nineteen or twenty, transferred to him at the Massachusetts General Hospital. It was supposed that she might have ovarian cyst. Circumscribed fluctuation could be made out. On opening the sac-wall by a cut eleven inches long, the case was found to be encysted tubercular peritonitis. A drainage-tube was used with iodoform and the patient has done well. There is still discharge through a sinus.

DR. E. N. WHITTIER said, the large female ward at the Massachusetts General Hospital was fruitful in abdominal tuberculosis, for in addition to the case cited by Dr. Cabot, transferred to him for surgical treatment, there was that of Caroline Morgan. This young woman entered in June, and on the 22d of July, was tapped, and 106 f3, highly albuminous

fluid were removed from peritoneal cavity. In September, 136 f3 were removed, containing two per cent. albumen; in October, 172 f3; and the fluid re-accumulating in the latter part of the same month, he made an opening in the median line, in the usual place for tapping, and inserted a large soft-rubber drainage tube, and connected this by a smaller tube with a pail partly filled with carbolized water, under the bed. The peritoneal cavity never refilled, and the patient was discharged on the 27th of November, 1886.<sup>2</sup>

#### THE AMERICAN LARYNGOLOGICAL ASSOCIATION.

##### NINTH ANNUAL CONGRESS.

The ninth annual meeting of the Association was held in the hall of the Academy of Medicine, New York, May 26, 27, and 28, 1887. The President, DR. E. FLETCHER INGALLS, of Chicago, occupied the chair.

##### THURSDAY. — MORNING SESSION.

The meeting was opened by the delivery of the

##### PRESIDENT'S ADDRESS.

He referred to

##### INTUBATION OF THE LARYNX.

The history of the operation, and a description of the instruments used in the operation, were given. The method of operation was then referred to. In 1858, an attempt was made, in Paris, to treat stenosis by intubation. Seven cases were operated on, and of these, five died, and two cases recovered, after subsequent tracheotomy. In 1880 O'Dwyer introduced intubation, and gave to the profession one of the most useful operations of modern times. In the after-treatment, while the tube is in position, no liquids should be allowed. Sometimes small quantities of liquid can be taken, but the danger of exciting bronchitis or pneumonia is so great, that fluid should be entirely prohibited. The largest tube that can be introduced is the one most likely to be retained. The danger of the tube being forced into the trachea was referred to. In four or six days, in favorable cases, the swelling and false membrane will have so much diminished that the tube will be coughed up finally, and need not be re-introduced.

The speaker had performed intubation in twelve cases of diphtheritic laryngitis. In three cases, recovery followed. By a coincidence, the cases of recovery were the only ones in which the author had charge of the after-treatment. One case lived eight days, and then died suddenly an hour after the tube had been removed. Another lived eight days, and then died of pneumonia. Details of the cases treated were given. As a result of his experience, he concludes that the treatment after intubation should be: (1) Prohibition of fluids, except by enemata. (2) Some preparation of mercury should be given in large and frequent doses. (3) In case of development of bronchitis and pneumonia, respiratory and cardiac stimulants should be given freely, but cautiously.

<sup>2</sup> I examined this patient on the 29th of April, 1887. There exists to-day no evidence of any abdominal disease. The rational and physical signs were those of tuberculous peritonitis; and this statement is made as a contribution to the opinion that is gaining ground, that there is in permanent drainage of the peritoneal cavity, in uncomplicated tuberculous peritonitis, a method of treatment productive of satisfactory and permanent good results. E. N. W.

By correspondence and study of the literature, he had collected 514 cases, with 134 recoveries. The percentage of recoveries will be greater when more care is exercised in the use of fluids. When medicines fail, no time should be lost in providing for the free entrance of air, either by intubation or tracheotomy. Intubation can be done more quickly, more safely, with less shock to the patient, and less objection on the part of the parents. The operator should be prepared to open the trachea if loosened membrane should be forced down into the trachea. When the tube fails to relieve dyspnea, tracheotomy should be performed, unless there is reason to believe that the latter operation will fail. Where membrane is loose in the trachea, no time should be lost in the use of forceps, which rarely succeed, but tracheotomy should be resorted to. The results obtained by intubation are about as good as tracheotomy at all ages, but apparently better in young children.

#### A STUDY OF SOME OF THE OBJECTIONABLE FEATURES OF INTUBATION,

by CHARLES E. SAJOUS, M.D., of Philadelphia.

At present, statistics favor the operation of tracheotomy, but the author believed that intubation would prove the better operation when the mechanical defects are overcome. The principal objections, according to the degree of danger, are: (1) The tendency to the obstruction of the tube by fragments of membrane. (2) Crowding down of loose membrane during introduction of the tube. (3) Passage of food into the trachea. (4) Momentary arrest of respiration during introduction of tube. (5) Liability of the tube to be coughed out. (6) Slipping of tube into the trachea. The tendency to obstruction was attributed to the limited diameter of the tube; the crowding down of membrane to the length of the tube; the passage of fluid to the weight of the tube; the liability to be coughed out to the limited diameter of the tube; and the slipping of the tube to the weight of the instrument and the formation of the head.

The speaker exhibited instruments on the principle of the bivalve speculum, which were intended to embody the suggestions made above. This tube obstructs the larynx very little, leaving the breathing space almost as great as normal. The author also exhibited an instrument intended to remove loose membrane from the larynx. The instrument consisted of forceps, which could be protruded into the larynx, by an arrangement in the handle, the required distance, and the membrane grasped.

#### DISCUSSION.

DR. F. H. HOOPER, of Boston. I have had no personal experience with the operation, but I have watched certain cases in the Boston City Hospital since last October. Ten cases of intubation have been operated on, with two recoveries. In one case, the attempt to introduce the tube caused spasm, and tracheotomy was performed. In every case, there was immediate relief to dyspnea. In three cases, the tube was coughed up and swallowed.

DR. D. BRYSON DELAVAN, of New York. An interesting question is with reference of feeding. It has been suggested that feeding with a tube introduced into the œsophagus would overcome the difficulty. I think this is worthy of consideration. This plan can also be used in cases of tracheotomy.

DR. MORRIS J. ASCH, of New York. There are a few objections which should be brought to the notice of the profession. One of these is that membrane may be crowded down which is very difficult to remove, even by tracheotomy. Another objection is the difficulty experienced by the ordinary practitioner in the removal of the tube.

DR. B. F. WESTBROOK, of Brooklyn. I do not think that the weight of the tube is what causes the trouble in deglutition, for the muscles which elevate the larynx are quite strong. It seems to me more likely that the difficulty is due to the rigid tube, which holds the larynx open. In normal deglutition, the entrance of the larynx is closed.

DR. S. H. CHAPMAN, of New Haven. One of the most distressing symptoms after the introduction of the tube seems to be thirst. It would be interesting to study the cause of this. Could it not be relieved by the use of enemata and by baths? It may be occasioned by the use of the mercury, which might be introduced in some other way than by the mouth. The use of pilocarpine, which, even in small doses, causes salivation, might be of service.

DR. E. FLETCHER INGALLS, of Chicago. It is so rare that the tube becomes clogged, that it is not necessary to have a skilled attendant. When the tube becomes clogged, it is usually coughed up, and, as a rule, it is not necessary to replace it for two or three hours. The attempt to feed these patients through a tube introduced into the œsophagus has been tried in Chicago, but I have not heard any stress laid on this measure.

#### DESCRIPTION OF A MODIFIED LARYNGECTOMY,

by J. SOLIS COHEN, M.D., of Philadelphia.

The operation is applicable to those cases in which the disease is not too extensive, and has the advantage over complete laryngectomy of leaving the greater portion of the thyroid cartilages undisturbed while the respiratory portion of the larynx is removed. On the cadaver, the operation can be performed in two minutes. In disease limited to the interior of the respiratory tube, especially carcinomatous disease, it fulfills every indication that prompted complete laryngectomy. The advantages claimed for the operation were: (1) Rapidity, ease, and comparative safety for the patient. (2) The small size of the wound. (3) The preservation of the attachment of various important muscles and ligaments. (4) The retention of important structures in their normal relation. (5) A firm, natural support is left for the application of any artificial apparatus. The operation should be performed for complete laryngectomy when not precluded by the extent of the disease.

#### THE PRESENTATION OF INSTRUMENTS

was next in order.

DR. T. A. DE BLOIS, of Boston, exhibited a portable apparatus for compressing air.

DR. E. C. MORGAN, of Washington, presented a universal powder-blower, which could be used in diseases of the nose, throat, vagina, or rectum.

DR. ALLEN, of New York, exhibited an improved form of snare, which could be used with one hand.

The following were appointed as the nominating committee: Drs. Beverly Robinson, of New York, W. C. Glasgow, of St. Louis, and S. H. Chapman, of New Haven. Adjournment of morning session.

## AFTERNOON SESSION.

## THE PATHOLOGICAL NASAL REFLEX. — AN HISTORICAL STUDY.

by JOHN N. MACKENZIE, M.D., of Baltimore.

The fact is established beyond doubt that a causal relation exists between diseases of the nasal mucous membrane and other portions of the respiratory tract and many conditions of distant parts of the body. Hay fever can be traced to the time of Galen. The fact that tickling the nose would arrest hiccough is referred to by Plato. The irritating effects of the odor of flowers was recognized in very early times. Reference was made to the observations of various individuals in regard to reflex conditions due to nasal disease. During the eighteenth century much was written upon this subject.

## HAY FEVER: ANALYSIS OF CASES, WITH RESULTS OF TREATMENT.

by JOHN O. ROE, M.D., of Rochester.

Up to the last hay fever season, the author had treated forty-two cases. A study of these cases tended to confirm the opinions expressed in February, 1883. Some of these views have been modified. Of the forty-two cases twenty-six were males and sixteen females. The attacks came on between May 1st and August 1st. In all, the active symptoms subsided soon after the appearance of frost. In some cases the hay fever dated from a severe attack of cold. In every instance there was disease of the nasal passages. The location of the sensitive areas is not constant, but they are usually most marked over the areas of greatest hypertrophy. The areas have not been confined to the posterior portion of the turbinated bone, nor especially to the anterior portion of the turbinated bones. In the majority of cases the septum was as sensitive as the turbinated bones. Thirty-one patients suffered with asthma. But twelve patients had a distinctly nervous temperament while nine were distinctly phlegmatic.

The plan of treatment adopted is to restore the nasal passages to as near as possible a normal condition and destroy the sensitive areas. These areas are to be destroyed by cauterization. Deep cauterization has been most effective, while superficial cauterization had no marked effect. The condition of the larynx, pharynx and bronchi must not be overlooked. Not infrequently enlarged tonsils will keep up irritation in the turbinated bones. A neglect to cure a bronchitis may account for the return of the disease.

Thirty-five of these cases have practically been cured, seventeen have remained exempt for periods varying from one to nine years, four were not relieved owing to imperfect treatment, and four have been lost sight of. The following conclusions were presented:

(1) All cases of hay fever have the initiative lesion in a diseased condition of the tissues of the nasal fossa.

(2) All diseases of these tissues induce in the ganglionic centres connected with them an abnormal activity which is reflected to other organs.

(3) The sensitive areas in the nose are not found in any particular portion of the cavity. Nor are there any zones which when irritated produce always the same manifestations.

(4) The direction in which the irritation is reflected is always in the line of least resistance. Irritation in

the same region may be reflected in one direction at one time and in another direction at another time.

(5) The disease in the nose may produce disease in other portions of the respiratory tract which may become independent centres of irritation.

(6) The affection recognized as hay fever is due to local irritations brought in contact with the sensitive areas in the nose.

(7) The affection is not *per se* neurotic, nor is the so-called neurotic condition of the person necessary to render a person susceptible to local irritation applied to the air-passages. It is not necessarily associated with the nervous temperament.

(8) The neurotic condition which is often regarded as the cause of the hay fever, is often the result of the local irritation.

(9) By careful and thorough treatment of the disease of the nasal tissue combined with that of other portions of the respiratory passages below, which have become secondary sources of irritation, we need not fail to cure hay fever.

## DISCUSSION.

DR. C. E. SAJOUS, of Philadelphia. At the last meeting I reported some cases in which the use of the cautery had been only of temporary benefit. I now believe that the failure was due to the fact that the cauterization was only superficial. Since I have employed deep cauterization I have cured the disease.

DR. J. N. MACKENZIE, of Baltimore. I regard hay fever as a neurosis. That it is a disease of the nose producing reflex symptoms, I think is not the fact. Where in hay fever disease of the nose is found, the question arises whether this is primary or secondary, or whether it is only an accidental condition. There is, I think, always some more central cause than the affection of the nose. Where the disease is recent it may possibly be arrested by local treatment, but where the affection is of long standing I do not believe that simple local treatment of the nose will overcome the difficulty. Last summer in treating hay fever I made no application to the nose, and I think that my results were better than ever before. I gave in large doses, zinc, *nox vomica*, quinine and arsenic.

DR. F. I. KNIGHT, of Boston. I would ask if any of the members have had any experience with diversion of nervous influence in any of these cases? In one case coming under my notice the attack was arrested by the patient breaking his leg. Another patient had the attack arrested after consulting a disciple of mind-cure.

DR. W. C. GLASGOW, of St. Louis. I think the evidence shows that hay fever is not a local affection, but that it is a general nervous disturbance. It is difficult to judge of the influence of treatment, for in the same individual the severity of the attack varies from year to year. I believe that constitutional treatment is an important element in the case. Unless the disposition toward the disease can be eradicated I cannot believe that a perfect cure can be attained by the destruction of the mucous membrane of the nose.

DR. F. H. HOOPER, of Boston. I have regarded hay fever as a neurosis and have treated it in the manner spoken of by Dr. Mackenzie. This accomplishes great good, especially in young children. I have at present under treatment a case in which there is hay fever with asthma. Until this gentleman came to me a few weeks ago his nose had not been ex-

amed. I found in the right nostril a sharp ridge running along the septum and coming in contact with the inferior turbinated bone. On the left side was a similar ridge. With this exception there is no special disease of the nose.

DR. J. SOLIS COHEN, of Philadelphia. I think that the views of Dr. Mackenzie are very nearly correct. It has been my experience that poor people rarely become the victims of hay fever. I have always thought that in addition to the neurotic element, codling and high living had something to do with the induction of the affection. Many cases occur in those who are overworked and have resorted to stimulants. These patients are often benefited by rest in the mountain or at the seashore. I have obtained benefit by tonic treatment, modifying the diet and restricting the use of meat. The more we look upon this as a constitutional affection and the less as a local condition the sooner will we get at the truth. A large number of these sufferers have obstruction in the nasal cavities, but many have no such obstruction.

DR. J. O. ROE, of Rochester. I consider hay fever as the reflection of some irritation from the nasal chambers, which irritation is produced by some foreign substance coming in contact with the mucous membrane of the nose. Irritation reflected from other situations to the nasal chambers is not hay fever. I think that Dr. Mackenzie includes some such cases. I have never seen any evidence to show that this was a neurosis.

#### ON THE TREATMENT OF ATROPHIC RHINITIS BY APPLICATIONS OF THE GALVANIC CURRENT,

by D. BRYSON DELAVAN, M.D., of New York.

Some years ago Dr. E. L. Shurly, of Detroit, recommended the use of the galvanic current in the treatment of dry catarrh of the pharynx, and related cases in which benefit had followed its use. He also advocated the same treatment in atrophic rhinitis. The author had tried this method of treatment in certain cases. The positive pole of a constant current battery was applied to the nape of the neck, while the negative pole was applied directly to the mucous membrane by an electrode consisting of a copper-wire around which absorbent cotton is wrapped. The strength of current employed varied from four to seven milliamperes. In more recent cases of the affection the effect is marked, but even in the older cases the method is not without benefit. The author had found this measure useful in these cases, and reported illustrations. The objection to the method is the amount of time which it requires.

#### DISCUSSION.

DR. T. A. DeBLOIS, of Boston. I have had the opportunity of applying this method of treatment in two cases, one of atrophic and the other of hypertrophic rhinitis. In the first case there was almost complete loss of smell and taste. The applications were made three times a week for six months. Both cases were improved.

DR. F. I. KNIGHT, of Boston. I would ask what experience the members have had with the use of plugging of the cavity of the nose? I have used this measure and produced relief of the most distressing symptoms. One side of the nose is thoroughly stopped with a piece of absorbent cotton which is allowed to remain three hours during the morning.

It is then removed and the other side is stopped in the same way for three hours in the afternoon. I have never had the least disagreeable effects from the use of the cotton in this way. The bad odor is greatly lessened.

DR. J. O. ROE, of Rochester. I have used the plugs of cotton, but with no other effect than to set up irritation. I have used with marked benefit the application of a weak solution of nitrate of silver, five or ten grains to the ounce, the parts having previously been cleaned. This applied every other day almost entirely relieved the symptoms.

DR. C. E. SAJOURS, of Philadelphia. The good effect obtained by Dr. Delavan was probably due to the irritating effect of the negative pole. I have used in two cases with absolute relief of the symptoms the application of chromic acid in a solution made by simply allowing the acid to absorb moisture from the air.

#### MYALGIA OF THE PHARYNX AND LARYNX,

by DR. S. H. CHAPMAN, of New Haven.

The speaker called attention to certain peculiar conditions of the muscles of the upper air-passages, which occur oftentimes in malarial disorders, and which on account of their severity are brought to the notice of the specialist. The muscles most likely to be affected are the pectoral, the muscles of deglutition and those of the voice.

#### SENSORY AFFECTION OF THE THROAT,

by DR. F. I. KNIGHT, of Boston.

The principal experience of the author had been with hyperesthesia and paræsthesia. In hyperesthesia, the general condition of the patient is, as a rule, not sufficiently considered. The worst cases are alcoholic subjects and those with digestive disorders. These will often yield to withdrawal of the alcohol and regulation of the diet. Astringents are frequently of service. In the cases of paræsthesia which he had seen there had been a feeling of fulness, pressure, burning, globus hystericus or the sensation of a foreign body in the throat. In these cases there is impairment of the general nervous system. The exciting cause may be some disease of the throat. Fatigue usually exaggerates these sensations. He had never met with paræsthesia of the larynx as the earliest symptom of phthisis, as had been claimed by some observers. The prognosis in most cases of paræsthesia is good if a careful treatment be carried out. The treatment of the neurosis of sensation must be claimed to cure the constitutional vice.

DR. W. C. JARVIS, of New York. I recently saw a man complaining of pain on either side of the tongue which had existed for the past two years. He was suffering from the effects of syphilis, and with the neuralgia of the tongue there was frontal neuralgia and pains in other parts of the body. I have another patient who consults me every five or six months on account of a severe pain in the right anterior pillar of the fauces. He believes that it will terminate in cancer. It will disappear for a week at a time and then return. I believe that in this case the trouble is psychical, and that there is no pathological lesion to account for it.

DR. C. E. SAJOURS, of Philadelphia. I have seen two or three such cases. In one there was follicular pharyngitis, and although the pathological condition was cured the pain remained. The pain seemed worse

in damp weather, and the gentleman had the habit of bathing every morning in cold water. The history of the case seemed to indicate a rheumatic trouble, and such may have been its nature.

DR. W. C. GLASGOW, of St. Louis. Many of these cases, I think, are due to malaria and some to the gouty diathesis. Sometimes the trouble is kept up by a single hyperæsthetic follicle. A reduction of the inflammation will be followed by a subsidence of the neuralgia. Sometimes the source of irritation is found with difficulty. In the rheumatic cases there is usually exacerbation at night. These affections in some cases appear to have a tendency to the induction of melancholia. Adjourned.

(To be continued.)

#### AMERICAN ASSOCIATION OF GENITO-URINARY SURGEONS.<sup>1</sup>

DR. P. A. MORROW read a paper on

#### IDIOSYNCRASY AS AFFECTING THE SPECIFIC TREATMENT OF SYPHILIS.

The author first refers to the ample justification of the claims of mercury and iodide of potassium to be ranked as "specifics" in the treatment of syphilis. These agents when introduced into the organism directly attack and cause to disappear the organic lesions as well as the functional disorders created by the syphilitic virus. Experience shows, however, that the action of these drugs is by no means constant and infallible. All syphilis are not equally susceptible to this curative action. The definite peculiarities of constitution which are generally included in the term idiosyncrasy, exert a dominant influence in modifying drug action. The therapeutic action of specific remedies is especially subordinated to conditions of aptitude inherent in the individual.

Idiosyncrasy in relation to the action of mercury and iodide of potassium may be manifest in various modes and degrees of intensity: (1) In an abnormal susceptibility to their physiological or toxic effects. (2) In the production of incidental ill effects which may be associated with the drug's physiological action, or may take the place of it, constituting an aberration of the drug's typical mode of action. (3) In an insensibility or failure on the part of the system to respond to the curative action of these drugs.

Various clinical examples were given illustrating the foregoing propositions, particularly cases of idiosyncrasy against the iodide so marked that the local and constitutional disorders caused by the drug surpassed in severity the symptoms of the disease itself. In one case under recent observation ordinary medicinal doses of the iodide repeatedly caused a multiform eruption consisting of pustular, bullous, nodular, and keloidal lesions, attended with the most pronounced symptoms of constitutional "iodism." The specific lesions were much aggravated under its use.

The various expedients which have been recommended to secure tolerance of these drugs by counteracting their ill effects were enumerated in detail, and their comparative value considered.

In conclusion, the author suggested that the practical significance of idiosyncrasy and its bearing upon treatment had not received from specialists the consid-

eration its importance demands. The rules of treatment had been rigorously and mathematically formulated — so many months of mercury, and after a certain date recourse to the iodide of potassium without reference to the immense variance in the constitution and idiosyncrasies of patients, not only in the toleration of those drugs, but in susceptibility to their curative action.

#### OBSERVATIONS ON THE USE OF OIL OF WINTERGREEN IN THE TREATMENT OF GONORRHOEAL RHEUMATISM.

DR. R. W. TAYLOR, of New York, detailed the histories of about twenty cases of gonorrhoeal rheumatism occurring in the Charity Hospital the past year, in which he had given the oil of wintergreen a thorough trial. In about nine of the cases the disease was of that chronic kind, in old or neglected subjects, in whom no treatment could prove of much benefit. In the others the benefit was marked, and most of them after some weeks recovered entirely. The drug was administered in capsules in pretty large doses, varying according to the circumstances. The urethral secretion also became bland under the action of the drug, and disappeared. Other remedies had in most cases been tried with little or no effect.

#### A FEW PRACTICAL OBSERVATIONS ON THE TREATMENT OF LATE NEOPLASMS OF SYPHILIS.

DR. ALGERNON S. GARNETT was the author of the paper, which in his absence, was read by the Secretary. He thought it was an error to give fixed doses, especially in the latter stages of syphilis, without due regard to the nature of the case. He believed in removing neoplasms, slight or grave, and considered no patient safe as long as there was the slightest evidence of the disease. The iodide of potassium or mercury should be pushed in every stage of syphilis as far as it could be borne. If cachexia in the later stage prevented the free use of mercury, tolerance of the drug must be cultivated until the patient could be put under its full influence. Syphilis, he thought, was not a benign disease at all.

The President exhibited a Reverdin instrument which he had modified for the purpose of performing subcutaneous ligation in varicocele in the manner he had described about two years ago.

#### SECOND DAY. — MORNING SESSION.

Dr. Keyes was re-elected President, and Dr. R. W. Taylor, Secretary and Treasurer.

#### ON TEMPORARY OVERSTRAIN OF THE BLADDER PRODUCING CHRONIC RETENTION OF URINE.

DR. F. N. OTIS introduced his subject by defining the usual causes and varieties of atony of the bladder. It was stated, as generally understood, to result in a loss, more or less complete, of the contractile power of the bladder, from over-stretching. This usually occurred through long-continued obstruction from enlarged prostate or organic urethral structure, especially in elderly persons. It was also recognized as occasionally resulting from sudden overstrain through even a single attack of retention from the same cause. Dr. Otis desired to call attention to this latter form, and especially when it occurred independent of any organic obstruction, but probably as a result of reflex irritation caused by a contracted meatus urinarius or urethral stricture of large calibre. Such

<sup>1</sup> Concluded from page 532.

reflex trouble might, however, result from the irritation of hemorrhoids. Again, the retention might be caused through temporary loss of consciousness or any nervous shock or from sexual excess. However produced, he claimed that a single retention of urine from any cause, might, within the space of a few hours, produce such an overstrain of the muscular structures of the bladder as to necessitate in some cases the use of catheter for the passage of every drop of urine during the remainder of the patient's lifetime. Several cases were cited in proof of the occurrence of acute retention from reflex causes, which were promptly and permanently relieved by division of a urethral contraction. To show in how brief a period overdistention of the bladder might occur, one case was cited, when twenty-three ounces of urine had been secreted within six hours, resulting in atony, involving the complete loss of the voluntary power of urination for several days. Another case where the accidental neglect to urinate on going to bed, had caused a total loss of voluntary power of urination for over two years. Other cases were cited where more or less complete retention had resulted in practically the same way. In none of these was there any prostatic enlargement, or close stricture. There was besides this no general atony of the bladder, as proven by the ability to increase to a normal degree the strength of the flow of urine through the catheter. From this fact, Dr. Otis assumed that the overstrain had been local, chiefly in that portion concerned in opening the vesical orifice. This was claimed to be the point where the greatest strain would occur in a sudden retention of urine. The portion thus weakened was unable to overcome the resistance of the muscular structure of the so-called vesical sphincter, and retention was the result.

In the case above noted where a complete loss of the power of voluntary urination had existed for over two years, removal of anterior strictures had failed to give relief. Subsequent exploration of the parts through a perineal section, failed to show any mechanical obstruction. A division of the structures of the vesical neck, thus weakening their resistance to the detrusor, overstrained and atoned at the base found, promptly restored the power of voluntary urination to some degree, and continued relief of the strain by systematic catheterization for several months, finally resulted in a complete recovery.

Dr. Otis claimed that in cases of sudden overstrain of the bladder by acute retention the damage was most likely to be an overstrain of the muscular structures in the vicinity of the base found, producing a local and not general atony; and that when atony of the bladder was not relieved by measures addressed to restoring the general tonicity of the bladder, the cure might be expedited by a division of the muscular structures of the vesical neck, even if no obstruction like a bar or other obstacle at the neck of the bladder could be detected.

Dr. Otis, in conclusion, summed up the suggestions which, in reviewing the cases cited, appeared most salient:

*First.* The importance of recognizing the influence of even slight urethral stricture in producing sudden retention of urine.

*Second.* The importance of early recognition and relief of such retention by catheter, and in this connection, the author advised against a too rapid emptying of the bladder, and stated that by a gradual with-

drawal of the urine, the danger of syncope, hemorrhage and cystitis were to a great extent avoided.

*Third.* That a localized atony, confined to the base of the bladder, may be present in sufficient degree to prevent voluntary urination while the contractile power of the superior portion of the bladder remains practically undiminished.

*Fourth.* That failure to restore the urinary function in such cases through general medication and local measures, including the removal of possible sources of reflex irritation in the urethra, suggests possible cure even in long-standing cases through incision of the vesical neck.

#### EARLY SYPHILITIC EPIDIDYMITIS.

Dr. J. N. HYDE, of Chicago, read a paper with this title.

The author cited cases which had come under his observation with a view of presenting the negative side of the subject. The following propositions, he thought, rested on fairly sound clinical grounds:

(1) A male patient may suffer from blenorraghic epididymitis on one side, subsequently contract syphilis, yet escape syphilitic involvement of the epididymis. (2) A male patient may suffer from blenorraghic epididymitis involving first one organ, then the other, finally acquire syphilis and escape syphilitic epididymitis. (3) A male patient may suffer from blenorraghic epididymitis of one or both organs, become so irritable as to exhibit by inflammatory accidents sympathy with successive blenorraghic attacks, yet throughout a final syphilis betray no sensitiveness to the last-named disease. (4) A male patient affected at the same time with syphilis and blenorraghia may suffer from an epididymitis evidently a complication of the last-mentioned disease, namely, blenorraghia, and yet escape syphilitic involvement of the organ. (5) A male patient may suffer from tuberculosis, subsequently incur syphilis, yet the epididymis escape involvement. (6) A male patient who has suffered from repeated attacks of blenorraghia, and that lately, may exhibit the typical form of early syphilitic epididymitis.

#### PROSTATOTOMY FOR OBSTRUCTION.

Dr. A. T. CABOT, of Boston, reported two cases of prostatotomy. In one, the operation was followed by almost complete recovery of the function of the bladder. In this case litholapaxy was done on the stone before the operation of prostatotomy. In the other case, although the first result of the operation was satisfactory, a certain amount of incontinence appeared some months later. Dr. Cabot ascribed this to the hypertrophied condition of the bladder which was sufficient to overcome the constrictor muscle weakened as a result of the incision into the membranous urethra. He queried whether in a case like this with good evidence of a hypertrophied bladder, and in which the obstruction was a narrow bar the internal prostatotomy of Mercier might not prove the better operation.

A PLEA FOR THE MORE GENERAL USE OF THE NITRATE OF SILVER IN THE DEEP URETHRA, WITH AN IMPROVED INSTRUMENT FOR ITS APPLICATION.

Dr. KEYES read the paper, and presented an instrument for injecting the deep urethra, which he believed was more suitable and more serviceable than other syringes in general use. His method is to deposit three to five minims of a watery solution of the nitrate

of silver of a strength varying from one to forty-eight grains in the ounce, very accurately in the centre of the membranous urethra, placing it there by the use of an instrument open at its tip. He thinks the method is not suitable in cancer, tubercle, or when the deep urethral symptoms are due to considerable periurethral inflammation, but most beneficial for inflammatory and neurotic surface disturbances of the deep urethra and neck of the bladder. He gave illustrative cases of cure of gonorrhoeal cystitis, relapsing epididymitis, vesical irritability, prostatorrhoea, etc.

In the full discussion on the paper which followed, most of the members expressed hopes of better results from deep urethral injections of nitrate of silver than had hitherto been generally attained. Dr. J. H. Brinton was one of the strongest advocates of this method which he had practised extensively. To relieve the discomfort or pain which the patient experienced after treatment by this or other methods, he had the patient stand by the basin and allow a small stream of water run over the corona of the penis; the relief was almost immediate. Dr. Mastin referred to the practice of Prof. Richardson, consisting in injecting a drachm of almost a saturated solution of nitrate of silver into the bladder in gonorrhoea and chronic cystitis.

Dr. R. W. TAYLOR, of New York, read a paper on  
A RARE FORM OF SEPTICÆMIA FOLLOWING INTERNAL URETHROTOMY.

The operation was performed in 1878 by a colleague, and the case was seen by Dr. Taylor in consultation. The occurrence of the accident complicating urethrotomy is unique in medical literature, and this consideration, together with the fact that the form of septicæmia is little known and only indifferently described by English and American writers, prompted the preparation of the paper. The patient was a perfectly healthy man, aged twenty-eight, who had a tight stricture of the bulbo-membranous junction which was incised by means of Maisonneuve's instrument. The operation was performed with all care. Within twenty-four hours severe pain attacked the perineal region, and soon a reddish boggy appearance was observed. Then the inflammatory action extended, and presented marked features. The integument became edematous, and a distinct emphysematous crackling was felt when pressure was made on the parts. As this rapidly extended, large brown patches of skin developed, which felt as hard as the rind of ham. Besides these there were large ecchymotic spots and deep blue-black lines which were caused by congestion and destruction of the veins. This condition extended over the whole body, which during life was much enlarged by the oedema and gas in the subcutaneous tissue, and after death the body became rapidly swollen beyond recognition and to fully twice its normal size, and was a deep purple, gangrenous mass, covered with large bullae, and emitting a horrible stench. Death took place eighty-seven hours after the operation. The subjective symptoms were rapid pulse, tremulous action of the heart, progressive and distressing dyspnoea, intense restlessness, utter agony and despair. The temperature at first rose, then fell below normal.

The disease was not accurately known until 1870, although many cases of it had been reported, particularly as occurring in the army, navy, and crowded hospitals. The cases were mostly epidemic. It started on the limbs generally, most frequently on the legs. It had

been called many names, but Dr. Taylor preferred the one proposed by Mollière, *septicæmie gazeuse foudroyante*. Reasons were given in support of the view that the disease is caused by a specific septic microbe. The only treatment is thorough amputation of the part in which the septicæmia begins, if that is practicable.

Dr. R. W. TAYLOR, of New York, then exhibited  
SECTIONS OF TUBERCULAR TESTES WITH BACILLI,  
AND THE CO-EXISTENT BACILLI IN THE SPUTUM.

The Association then adjourned to meet next year, time and place to be announced.

#### AMERICAN CLIMATOLOGICAL ASSOCIATION. FOURTH ANNUAL MEETING.

The fourth annual meeting of the Association was held in the Johns Hopkins University, Baltimore, Md., May 31 and June 1, 1887.

#### TUESDAY, MAY 31ST. AFTERNOON SESSION.

The Society was called to order by the President, Dr. FRANK DONALDSON, Sr., of Baltimore, who delivered the

PRESIDENT'S ADDRESS.  
PROPHYLACTIC TREATMENT OF THOSE WHO INHERIT  
A PREDISPOSITION TO PHTHISIS.

He referred to the great mortality of phthisis, but certain statistics compiled in this country and abroad show a decrease in the annual mortality. In England there has been a gain in males of fourteen per cent. and in females of twenty-two per cent.; in Massachusetts there has been a gain of 54 lives per 100,000.

Thirty per cent. of the cases have an inherited predisposition to the disease. The hereditary form when developed offers the least prospect of recovery. Reference was made to the pathology of the disease. Five years have elapsed since the contagion of tuberculosis was alleged to have been discovered, and nearly all observers have now confirmed the views of Koch. There is abundant evidence that human subjects readily yield to the bacillar poison, when previously they have been in perfect health. The bacillus is always present in phthisis, and we must accept it as the full explanation of the manifestations of tuberculosis. The disease may be propagated by the inhalation of the dried bacillus from the expectoration of diseased persons, by persons predisposed to tuberculosis. The various theories which had been advanced to explain heredity were discussed. The prophylactic treatment embrace two elements: (1) The improvement of the general health of the subject, and (2) the protection from contagion. The tuberculous mother should not nurse her child, but if possible it should be given to a healthy wet-nurse. The hygiene of the nursery should be looked after carefully. The room should be well ventilated and kept at a comparatively low temperature. The subject should live much out of doors, especially between the ages of fifteen and twenty years. The beneficial influence of sunlight should be borne in mind. All causes of glandular irritation should be avoided. Scrofulous glands should be dispersed or removed. The physical form of the chest should be enlarged by gymnastic movements. If possible, life should be passed in a high altitude. Olea-

ginous fluids are useful if they can be digested. The milk and flesh of tuberculous animals must be avoided, for cooking rarely destroys the bacilli of beef. If the prophylactic treatment is thoroughly carried out the hereditary proclivity may remain latent and the individual never contract the disease.

## DISCUSSION.

DR. JAMES C. WILSON, of Philadelphia. I think that the position taken by the author is what all should agree to; but, as we know, it is not accepted by all. Pulmonary tuberculosis in all its forms is in all probability an infectious, parasitic disease directly contagious.

DR. B. F. WESTBROOK, of Brooklyn. The anatomical and physiological conditions which predispose to this trouble are, according to the results of certain observations, a disproportion between the size of the heart and the lungs, the heart being smaller in proportion to the size of the lung than in the ordinary individual, and a disproportionately small digestive apparatus. The former condition interferes with the circulation at the apices while the latter condition causes a lack of nutrition.

## THE PHILOSOPHY OF CLIMATIC TREATMENT OF DISEASES OF THE CHEST,

by JAMES R. LEAMING, M.D., of New York.

It is observed that the greatest improvement takes place during the first three weeks of a patient's stay at a new place. The suggestion was made that a line of resorts be established along the Atlantic sea-coast. The patient could begin in the summer at the most northern, and gradually pass southward, making a stay of a few weeks at each place. Having completed the series, the patient may return, taking the stopping-places in a reverse order. This same plan might be applied to the Pacific coast and to the mountains. The speaker also suggested the propriety of State and municipal authorities furnishing sanatoriums for the benefit of those unable to avail themselves of the advantages of existing institutions.

## THE INFLUENCE OF SEA-AIR ON SYPHILITIC PHTHISIS,

by R. J. CURTIN, M.D., of Philadelphia.

The speaker gave in detail the histories of five cases of what appeared to be syphilitic phthisis, in which improvement followed prolonged sea-voyages, and in each case the symptoms returned when the patient again took up his residence on land. He was led to consider the cases observed as cases of syphilitic phthisis for the reasons that there were no symptoms of chronic pneumonia preceding the attack; that the lung trouble followed syphilitic infection, with constitutional symptoms; that the disease was influenced to some extent by constitutional treatment; and that there was no tendency to tuberculosis in these cases. He referred to the observations of Dr. William Porter, who relies upon the following points in reaching a diagnosis of syphilitic phthisis: (1) Abundant expectoration, without signs of softening. (2) A debilitated condition, without marked emaciation, and a rational history of phthisis. (3) Pronounced dyspnea, without evidence of cardiac or pulmonary obstruction to the circulation. (4) Pain along the sternum and the tibial crests. (5) The satisfactory response to treatment. Dr. Porter had examined the sputa in one hundred cases without finding the bacillus. The speaker was

not prepared to say why it was that the sea-air proved beneficial in these cases, while in most of the ordinary cases of phthisis residence on the sea-coast was not desirable.

## DISEASED CONDITIONS FOR WHICH SEA-AIR IS OF DOUBTFUL BENEFIT,

by BOARDMAN READ, M.D., of Atlantic City.  
(Read by title.)

## DISCUSSION.

DR. E. T. BRUEN, of Philadelphia. It is desirable that we should have correct views with regard to the influence of sea-air on pulmonary affections. It is probable that, in syphilitic phthisis, the benefit of the sea-air is due to its influence on the catarrhal processes. In catarrhal affections of the mucous membrane in general, it has seemed to me that residence at the sea-shore was useful. On the other hand, in tubercular phthisis, it has seemed to me that the influence of sea-air was disastrous. I am led to make these remarks because I find so many patients with phthisis recommended to reside at the sea-shore, or to take ocean voyages. I have found that those cases benefitted from prolonged sea-voyages are those in which there is no inherited tendency to tuberculosis.

DR. V. Y. BOWDITCH, of Boston. I should make a great distinction in speaking of the sea-coast air and the pure sea-air. Cases which could not stand the harsh, cold, and changeable air of the sea-coast may be benefitted by a sea-voyage or residence on an island some distance from the shore, where the conditions are similar to those which obtain on a sea-voyage.

DR. F. I. KNIGHT, of Boston. While I am sure that the general feeling is that the coast climate is not suitable for cases of phthisis, yet, in several instances, I have known patients to improve and gain in weight during a stay at some of the coldest resorts on the New England coast.

DR. JAMES C. WILSON, of Philadelphia. I have had no experience with syphilitic phthisis, but with reference to residence at the sea-coast in the treatment of phthisis, I would say that, in my experience, there are three classes of patients with consumption who cannot go to our exposed Atlantic sea-coast without risk: These are, first, those in whom there is active febrile disturbance; secondly, those of a highly excitable and nervous organization; and thirdly, those who suffer from repeated attacks of spitting of blood. Such patients cannot safely reside for any length of time on the Atlantic sea-coast.

DR. F. C. SHATTUCK, of Boston. The author has referred to syphilitic phthisis, that is to say, a destructive process in the lung not due to tubercle but to syphilitic virus. It seems to me to be a difficult matter to determine whether or not there is such an affection. Tubercular phthisis varies so much in its symptoms that the points mentioned I think cannot be relied on. It seems to me that the criterion would be the presence or absence of the tubercle bacillus. The author referred to Dr. Porter as having examined the sputa from one hundred cases of supposed syphilitic phthisis without finding the bacillus. That number is so large for the short time that this test has been available, that it would make us a little doubtful of the methods employed. The fact that the bacillus is not found, is no proof that it is not present. The German Committee on the Collective Investigation of

Disease, studied this matter last year and came to the conclusion that so-called syphilitic phthisis had no real existence. Both syphilis and tuberculosis are common diseases and the one offers no immunity from the other, so that we should expect to frequently find them combined in the same individual.

DR. J. H. MUSSEY, of Philadelphia. I have never seen a case of phthisis which I considered of syphilitic origin. In my experience in the post-mortem room I have come across only one case in which the lesions bore any resemblance to what we should expect to find in syphilitic phthisis. This was the case of a young man with syphilis and cirrhosis of the liver, due to syphilitic interstitial hepatitis; there were also syphilitic gummata in the brain, and the patient died of syphilitic meningitis. There were scattered through both lungs innumerable miliary granules not at all resembling miliary tubercles. These were solid bodies made up of a yellow core which was moderately firm and surrounded by a ring which made up at least one-half of the nodule. The microscopical examination showed these bodies to consist of a ring of firm fibrous connective tissue in the centre of which there were degenerating cells. We were unable to find the bacillus of phthisis, but as has already been stated, the failure to find it is no proof of its absence. I should not call this a case of syphilitic phthisis, but rather a case of syphilis of the lungs.

DR. E. FLETCHER INGALLS, of Chicago. I have been much interested in the remarks of the gentlemen from Boston, but I apprehend that most of us have seen cases in which the syphilitic nature of the disease admitted of no question. Even if the bacilli are found it would be no proof that the case had not originated as a syphilitic trouble and that it had subsequently become tubercular. I recall one case in which the syphilitic manifestations were very prominent. There was consolidation of the lungs, particularly of the middle portion of one lung. There was a history of syphilis and distinct cutaneous lesion. The patient had been in Colorado and returned much worse. On his return to a lower altitude he was put on the use of iodide of potassium and ultimately apparently recovered.

The papers were also discussed by DRs. FORD, of Utica, and FRANK DONALDSON, JR., of Baltimore.

THE TREATMENT OF THE FINAL STAGE OF PHTHISIS, by DR. J. H. MUSSEY, of Philadelphia.

The paper consisted of a detailed account of the symptoms met with in the last stages of phthisis and referred to the various measures which he had found useful in these cases. To relieve the high temperature he had resorted to antifebrin with advantage. Quinine was found to act unsatisfactorily.

The president announced as the nominating committee, DRs. F. C. SHATTUCK, E. T. BRUN, WILLIS E. FORD, B. F. WESTBROOK and W. H. GEDDINGS.

Adjourned to evening.

— *Second colored citizen*: "Whafur?" — "Got suthin' good." "What is it?" — "Pollynaris watah." "Pooh! watah!" — "S good, though." "Wha's taste like?" — "Like yer foot's asleap." — *Pittsburg Chronicle*.

## THE BOSTON Medical and Surgical Journal.

THURSDAY, JUNE 9, 1887.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,  
94 BOYLSTON STREET, BOSTON, MASS.

### MEDICINE IN JAPAN.

DR. NORTON WHITNEY lately read before the Asiatic Society, at Tokio, a valuable paper on "Medicine in the far East," in which was contained much interesting information respecting physic in Japan, and the current number of the *Westminster Review* gives a good exposition of the subject.

It is noteworthy that it is within the lifetime of the present generation that this great empire has been opened to intercourse with foreigners, and during the last two decades rapid strides have been made in the way of medical development. To give an account of the medical schools now flourishing in Japan, and their thorough equipment with modern appliances, would take more space than is at our disposal in this article. Women are also allowed to practise medicine there, and have the same general privileges as in this country. Japanese ladies also regularly come westward to pursue medical studies.

It is an interesting fact that the history of medicine in Japan bears a marked resemblance to the same history as associated with European civilization in its rise and progress. Among the primitive Japanese, the "medicine man" was a priest and a sorcerer, and physic was allied with divination, and this has been the case, by the way, with all primitive societies. There seems to have been an irresistible tendency to associate disease with the baleful volitions and the enmity of evil spirits, and hence the necessity of exorcism and propitiation. The whimsical, heroic, and often disgusting, methods of treatment seem based on the belief that the body of the patient may thereby be rendered too uncomfortable a place for the demon to continue to inhabit.

The Japanese seem early to have possessed some knowledge of anatomy, derived from the dissection of monkeys, and their speculations as to the composition of the human body resembled the views entertained by the old Greek philosophers. Man, said the former, is a compound of wind, fire, water, and earth, plus a soul. One of the winds circulates in the arteries, and so

causes the pulse (this was also in accordance with the physiology of the school of Hippocrates), while one of the fires displays itself in fevers, and another wastes the frame in old age. The derangements of the four elements give rise to diseases. This theory was not widely different (as the *Review* writer shows) from that held by Hippocrates, who taught that the elements of the human body are four, from which are derived the four humors—blood, phlegm, bile, and black bile—which rule the four temperaments, and whose irregularities constitute disease.

About the third century of our era, the Japanese, through conquest, came in contact with the Koreans, and subsequently, with the Chinese, and medical practice underwent modifications. The diabolical theory of disease gradually gave way to more rational views as to causation; the Japanese faculty came to recognize food and drink, atmospheric conditions, as wind and cold, heat and moisture, as causes of sickness. So impressed, in fact, was a celebrated Buddhist physician with the conviction that most stomach and intestinal disorders come from over-eating, that he adopted the practice of starving his patients into health—a mode of treatment that was often salutary and successful.

Shampooing, acupuncture, and the moxa, as well as the induction of anesthesia by various narcotics (as hemp), have long been employed by Japanese surgeons. The medical school established A.D. 669, had a professor of shampooing, with ten pupils, and another of acupuncture, with twenty. In 820, five acupuncturists were attached to the Mikado. The operation, as practised by the Japanese, consisted "in driving fine gold, silver, or steel needles from one-half to three-quarters-of-an-inch into the flesh." The number of performances made at one time varied from one to twenty.

The use of the moxa was learned from the Chinese, who carry the date of its invention back to the year B.C. 2800.

A celebrated physician, Toku-hon, who lived in the sixteenth century, adopted common-sense methods in the treatment of disease, eschewed the stabbing and burning methods so much in vogue, and may be looked upon as the father of modern rational medicine in Japan. He died in 1630, at the age of one hundred and eighteen. "He held, like Asclepiades, that the true scope of his art was to help and foster the innate recuperative power of nature; and it is related of him, that being called to see a great man who lay ill of a violent fever, the first thing he did was to ask him what he liked and disliked most. The patient replied that, of all things, he should like to throw off all the bed-clothes, let the draughts blow around him, eat a melon, and drink plenty of cold water, all of which Toku-hon immediately and gravely prescribed. Can he have heard of Asclepiades, who, sixteen hundred years before him, professed it to be the physician's duty to heal safely, speedily, and pleasantly, consulting the patient's inclinations, and flattering his prejudices?"

#### MIDNIGHT CALLS.

DOCTORS are known to be exposed in various ways to dangers to which their non-medical neighbors are less liable, but there is one particular peril which menaces the doctor's safety from which other men are free. If a man is called out of bed at night and asked to go to a house where he is unacquainted, he naturally becomes suspicious and refuses to go, or takes precautions to guard against treachery. The doctor, however, finds it but a part of his ordinary experience to thus start out alone at dead of night, at the summons of a perfect stranger. We read of doctors who have thus been led into traps, but for the honor of humanity it may be said such occurrences are rare.

An attempt was, however, made a few nights ago to take advantage of this confiding spirit on the part of the profession. A medical man who lives in what may be styled the medical centre of Boston was roused by a ring at his bell, followed by a summons to a house in a street not far away, and in a perfectly respectable locality. The doctor made certain inquiries to make sure there was no mistake on the part of the messenger, but did not see the man at the door nor recognize anything different from an ordinary night call. He dressed and started. The street to which he went was brightly lighted on one side by an electric light, but the house to which he was called lay in deep shadow. The steps to the door were high with an area door below. When the doctor was within a door or two of the house to which he had been called he was suddenly conscious of some one moving in the dark at the side of the steps. It occurred to him that the messenger was either waiting to show the way or was just starting out to repeat the summons, and he turned to inquire of him if that was the house. His surprise was great to find himself facing a man who appeared to hold a pistol in his right hand (he certainly took the position naturally assumed by a man who threatens a traveller with a revolver, although the darkness left it a little uncertain whether he really held the weapon) and a cord in the left hand. At the same time the assailant said, "keep quiet, doctor; keep quiet, don't lift your hands." The doctor very naturally stood still and stared at the man and his revolver. His thoughts during the time he does not pretend to reproduce, but after a time, which may have been half a minute, though it certainly seemed much longer, he suddenly started across the street and took the road toward home. The man immediately ran parallel to the doctor on his own side of the street, as the doctor supposed to cut him off at the next crossing, but when the doctor turned at the corner he found that his assailant went the other way. The doctor therefore turned back, and followed far enough to see the man vanish in a labyrinth of small streets. A visit next day to the house from which the call was supposed to issue showed that nothing was there known in regard to the matter. Of course nothing can be certainly known as to the object of this midnight treachery, though robbery through intima-

tion was undoubtedly intended. The position of the man at a spot the doctor was sure to pass, and the cord in his hand leave abundant food for the imagination.

Inquiry reveals only one similar instance in this vicinity. A physician in active practice in Charlestown, was called at night to see a man on a ship said to be lying at a certain wharf. He did not like the locality and was tired and refused to go; inquiry on the morrow showed that no such ship was there.

Words are hardly adequate to express the feelings with which a medical man must regard such an occurrence, and the story needs no comments.

How doctors can guard against such treachery is not easy to say. To be forewarned is to be given a chance to be forearmed.

#### JACCOUD ON THE CAUSATION OF PNEUMONIA.

JACCOUD, whose work on "Internal Pathology" is one of the medical classics of the day, lately read before the Academy of Sciences a short paper, in which he takes a stand against the microbiotic theory of pneumonia, and argues in favor of the older view that pneumonia owes its origin to cold. He reports two cases occurring under his observation, where exposure to cold was the immediate antecedent of the attack and where the sputa before death, and portions of the lungs after death, presented multitudes of pneumococci.

His explanation of the presence of the latter is that these microbes are harmless to the healthy organism, but find a suitable habitat where they can multiply and flourish, when, from certain causes, the vital forces and the resistance of the tissues are weakened. "The human organism," he says, "contains constantly in itself multitudes of microbes of different species. It is a hostile environment for them when the functions go on normally, but when any severe perturbation impairs the physiological harmony, the vital resistance fails, and the previously hostile environment becomes a favorable one; the organism now becomes a prey to its own microbes."

This view is the one commonly held by the opponents of the bacterial pathology, and can only be disproved by facts of experimentation going to show that the supposed specific microbe is capable, of itself, of generating the disease, independently of the influence of cold or any other depressing influence.

#### MEDICAL NOTES.

— The somewhat ambiguous announcement has been sent to the JOURNAL: "Mantoni Giesshübler, the celebrated natural mineral water of H. Mantoni, at Karlsbad, Bohemia."

— A correspondent of the *Chemist and Druggist*, in describing how to make a percolator, mentions the following method of cutting a bottle: "I was first shown how to do it by an ingenious mechanic, and have since

seen the same published in Spons' "Workshop Receipts." Put the bottle on a level foundation, and fill up with oil (I use linseed oil, being able to use it in paint-making afterwards) as far as you wish the line of separation to be. Next get a rod of iron as large as possible, but small enough to go into the mouth of the bottle. Make the iron almost white-hot, and dip into the oil. In a very short time a crack will be heard, when the iron can be taken out, and the bottle will be found as neatly cut as if with a diamond. Should the bottle be very thick, and the crack not heard in a minute or so, a dash of cold water outside will settle the business."

— Mr. Thomas C. Platt, of New York, has adopted the somewhat remarkable course of resigning his quarantine commissionership *conditionally*, on the Governor's assuring him that he will appoint Col. Frederick D. Grant in his stead. The general condition of quarantine and health matters in New York seems to have been such as to require, in some cases, the application of disinfectants to the departments themselves; and Mr. Platt has not preserved his quarantine office in absolutely perfect odor. But, as the *New York Times* remarks, the laws of the State place the power to appoint quarantine commissioners in the hands of the Governor, and not in those of the out-going official.

— Reports dated the middle of May showed that, owing to the neglect of the Government in not enforcing vaccination, isolation, and disinfection, small-pox has become epidemic in the city of Santiago de Cuba. There are fully 500 hundred cases within the city limits, apart from those outside. The death-rate is estimated to be as high as 60 per cent., due to the fact that some 35,000 out of a population of 40,000 are supposed to be wholly unprotected by vaccination. The disease is spreading rapidly, especially among the 29,000 blacks in the city, and medical men expect that thousands will be swept away if stringent measures are not taken to check the disease. Meanwhile, steamers and other vessels sail daily to Havana, New York, New Orleans, and other ports. The epidemic of small-pox in the adjoining island of Jamaica is not over.

— The acting assistant-surgeon in charge of the quarantine at Delaware Breakwater, reports to the surgeon-general of the Marine-Hospital Service, that in the town of Lewes, Del., (population 1,900), from January 9th, when the first case appeared, to April 20, 1887, there were 836 cases of measles reported, and about 200 cases in the immediate vicinity of the town. The mortality was low, being only about 1.5 per cent.

The medical officer in charge of the Marine-Hospital Service, at Key West, (Passed Assistant Surgeon Glennan) under date of May 28th, reports to the surgeon-general that "out of a total number of five cases there have been three deaths and one recovery, and one with a probability of recovery," from yellow fever, "all originating in one infected premises. The danger apprehended was on account of the large number of unacclimated persons in the city, with every means

of outlet cut off. Many left in sailing-vessels, and, at my suggestion, Dr. Porter asked the Louisiana board to allow healthy persons to go from here this week, subject to inspection or detention at the New Orleans quarantine, which was granted. At this date no new cases have developed, but it is yet too early to say that the disease has been stamped out. In any event, the care exercised in this instance by the board of health, in guarding infected houses, fumigating and destroying infected material, and in promptly declaring the existence of the disease, (measures probably for the first time efficiently adopted in this place), has practically established an outside confidence in sanitary information emanating from here. . . . It is reasonable to suppose that the infection was introduced here by a Bolio family, who formerly kept the San Carlos and Fifth Avenue hotels in Havana. During the past winter they have brought over household goods and stored them in the adjoining house. It is said that Baker and his wife slept upon one of their mattresses. At a special meeting of the board of health this morning, at which I was present, this was recognized as probable. The disease may now be said to have three foci; and should the board of health now succeed in preventing its further spread, it will only be done by the utmost care and vigilance." A telegram, June 1st, reports four new cases in different localities. The War Department authorized the president of the board of health to use the hospital and the laundress quarters attached to the military barracks for the treatment of yellow-fever patients. Iron bedsteads and mattresses were sent from the marine-hospital stores.

The United States sanitary inspector at Havana, Dr. Burgess, reports that the furniture bought of Mrs. Bolio and used by the Baker family had been used in a hotel at Havana, and it is well known that many cases of yellow fever have occurred in that hotel during the last few years. He himself had treated five cases in it, and is of opinion that the old pillows, bedding, etc., were the sources of infection.

Inspection of vessels was commenced at the Delaware Breakwater quarantine June 2, 1887.

#### NEW YORK.

—The State Legislature adjourned without confirming Dr. Phelps as Health Officer of the port of New York, as was the case when the Governor nominated the same gentleman for the appointment last year, so that the perennial Dr. Smith still holds his own.

—The nineteenth annual commencement of the Woman's Medical College of the New York Infirmary took place May 30th, in the concert hall of the Metropolitan Opera House. There were seven graduates, and the address to the class was by the Rev. Henry J. Van Dyke, Jr. In the report of the Alumnae Association, which was read by Dr. Mary Bissell, allusion was made to the good work done by the graduates of the College in India, China, and Japan.

—There has been a considerable number of cases of pleuro-pneumonia among the herds in the neighbor-

ing county of Westchester, principally in the towns of Somers and Bedford, and some New York butchers recently went there and killed nearly two hundred of the diseased cattle. The owners receive from the National Government and the city of New York, jointly, \$40 per head for the stock thus killed, by direction of the State Inspectors. Most of the diseased cattle came from the West, and are supposed to have been infected when they arrived. Westchester County is for the present quarantined, and dealers there are prohibited from sending any cattle to the city.

### Miscellany.

#### POISONING BY PILOCARPINE.

DR. A. G. GLINSKY, of the Kharkov Alexandravskaia Infirmary, reports, in the "Proceedings of the Kharkov Medical Society," part 1, 1886, page 109, as we learn from the *British Medical Journal*, a case of poisoning by pilocarpine — the first of its kind, according to the writer, in medical literature. A gentleman who had been in the habit of using a solution of pilocarpine as a stimulant for the hair, swallowed a considerable dose of the fluid, instead of a solution of quinine. About five minutes afterwards, profuse perspiration, first of the face, and then of the whole body, set in, together with salivation. These symptoms were speedily followed by dimness of sight, prostration, trembling of the limbs, a sensation of cold, noise in the head, and a general sense of confusion. On seeing the patient, about an hour after the accident, Dr. Glinsky found profuse, cold, clammy sweat, in big drops, on the face and body, coldness of the limbs, slight cyanosis of the hands and lips, a subnormal temperature; pulse 84, full, dicrotic; respirations 14; profuse salivation, great contraction of the pupils, spasmodic shiverings, general restlessness, extreme weakness, and trembling of the lower extremities. The treatment consisted of the internal administration of tannin and emetics, together with the hypodermic injection of atropine (1-30 of a grain, given in three doses). A quarter-of-an-hour after the injections a striking improvement took place; the perspiration ceased, the pupils became dilated, and tremor disappeared, and on the following day the patient was quite well. Dr. Glinsky adds that, in the period of 1879-85, 160 cases of poisoning by 23 toxic substances were admitted to the Alexandravskaia Infirmary. In 85 of these, phosphorus matches supplied the poisonous material. He shows, by statistics, that this kind of poisoning finds an increasing number of victims in Kharkov every year.

#### THE TREATMENT OF DIPHTHERIA.

THE *Therapeutic Gazette*, May, 1887, discusses the treatment of diphtheria and outlines the treatment which the editor personally has come to adopt. The primary and probably the most important part of the treatment is the free use of local remedies, of which Monsel's solution is, according to his thinking, the most efficacious. It should be painted very freely over the affected parts every four hours, either undi-

luted or diluted with an equal bulk of glycerin. It is essential to exercise a certain amount of care and not have the brush so wet that the solution will trickle into the larynx, unless, indeed, this organ has been invaded by the disease. Next to the local treatment comes the administration of mercurials. "We have so frequently seen an apparently severe attack of diphtheria abruptly aborted in its inception under the influence of large doses of calomel," say the writer, "that we can scarcely believe that the drug has no pronounced effect. A grain of it should be put dry in the mouth of the child every hour or two until frequent very loose liquid evacuations are produced. In diphtheritic, as in other forms of angina, tincture of belladonna has seemed to us to also exert an almost specific effect. In the treatment of severe ordinary sore throat our routine plan is the free local application of the solution of subsulphate of iron, diluted or undiluted according to the exigencies of the case, the administration of mercurials in the manner just described, and the use of belladonna, five drops of the tincture every two to four hours according to the age of the patient. The results which we have obtained in simple sore throat indicate that in diphtheria the treatment acts not by any specific influence upon the disease-germ, but by curing a local sore throat, which is the initial lesion of diphtheria, and causes through a septic poisoning the constitutional disturbance. As a specific antiseptic medication we have used the oil of eucalyptus with apparent advantage. It should be placed in small shallow vessels near to the patient, and a sufficient heat be steadily maintained to keep the liquid boiling. In this way large quantities of the eucalyptus oil can be volatilized and the respiratory passages be perpetually bathed with the antiseptic." The inhalations of turpentine as practised by Dr. Delthill of Paris and the improvement upon his method introduced more recently by Dr. Schenker are also referred to. The results obtained both by Dr. Schenker and Dr. Siegel from its internal use of turpentine indicate that it has considerable value in diphtheria.

#### THE INDICATIONS AND THE RATIONALE OF WASHING OUT THE PUERPERAL UTERUS.

DR. J. HALLIDAY CROOM, President of the Edinburgh Obstetrical Society, read before that Society a paper on the indications for, and method of washing out the puerperal uterus, which appears in the *Edinburgh Medical Journal*, May, 1887. He formulates the circumstances under which antiseptic washing out of the uterine cavity is indicated as follows:

**Indications.**—1. Where, with localized tenderness over the uterus, there is a high pulse and temperature, and a fetid discharge. It is to be observed that the discharge must be fetid from the uterus. In order to decide this question, it is essential to wash out the vagina with an antiseptic wash—inodorous, such as corrosive sublimate—and then putting the finger up and into the cervix, to decide whether it is fetid or not. As I shall have occasion to point out in the sequel, all first washings out should be performed under chloroform, therefore I always explore the cavity of the uterus with the finger. I need not here refer to the ease with which this can be performed, at least, during the first week of the puerperium. Even at a long period after labor, the carbolyzed fingers can be

comparatively easily introduced. In most cases some morbid product will be found, and in all cases, the necessary dilatation of the cervix will much facilitate the process of washing out.

2. Where, with a high pulse and temperature, there is any question as to the absolute complete delivery of the placenta; and, in this connection, it is impossible to emphasize too strongly the importance of examining closely the placenta after delivery, whether it be expressed, extracted, or delivered spontaneously. Such care will often eliminate at once any possible cause of infection.

3. Where portions of membrane have been retained *in utero*, and give rise to increase in pulse and temperature. Here, however, let me say it is possible to do harm in endeavoring to remove the membranes completely at the time of delivery. It is much better to leave a portion of membrane than to open up the genital canal in search for a small piece.

4. After the birth of a putrid fetus.

5. Where the uterus remains abnormally large after labor, and where, as a result, owing to the presence of decomposing clot, symptoms of septic infection develop themselves. In such cases, washing out ought to be accompanied by the introduction of the finger within the uterus, and in all such cases quinine ought to be administered in large doses.

6. In cases where, late on in the puerperium, symptoms of septicæmia develop themselves.

7. In those somewhat rare, but well-recognized cases, where, from acute flexion of the uterus, the lochia are retained and decompose.

8. In some cases of imperfect abortion and premature labor, and in all cases where the uterus, under such circumstances, has been curetted.

9. In all cases where the hand has been introduced—say in cases of post-partum hemorrhage, adherent placenta, or uterine hydatids—washing out the uterus with hot antiseptic water is the recognized treatment.

**Rationale.** "What is the rationale," the author next asks, "of washing out the puerperal uterus in septicæmia?" It seems, at first sight, open to doubt how far washing out the uterine cavity can prove effective in checking septicæmia if rapidly multiplying microbes have already passed into the system.

This point was alluded to during the interesting discussion which took place last session on the relation of microorganisms to puerperal fever, namely, that microorganisms require the condition of rest for their development. They do not multiply in the circulating blood. Dr. Freeland Barbour neatly and forcibly puts it thus: "That in those cases the toxic material does not multiply in the blood, but is generated in the uterus alone, from which it is served out into the system and eliminated by the excreting organs. The relation might be illustrated from the gas-supply of a city, in which the gas is, of course, produced at the retorts at the central work, and is simply served through the pipes and eliminated at the burners. By washing out the uterus, we put out the retorts and stop further production, the elimination of the poison being only a question of time." The value of washing out the uterus is confined to those cases where the septic material is developed in, and confined to, the uterine cavity. Where the development of the toxic material has gone beyond this, or where the septicæmia is developed originally outside the uterus altogether, obviously washing out the uterus will be of no avail.

## Correspondence.

## A NEW TREATMENT FOR PHLEBITIS OF THE LEG.

BOSTON, June 1, 1887.

MR. EDITOR,—I would record the fact that one case of recurrent deep phlebitis of the legs in an adult male, yielded well to a form of treatment not according to the routine generally followed and taught hereabouts.

In the patient referred to, three attacks to date have been under close study during the last eleven years; routine treatment was given during the two first attacks, namely, entire rest, elevated position of leg and opiates with hot fomentations. A very decided temporary paralysis of the feet and lower legs resulted from this disuse of the parts and the treatment. In this last attack no entire rest, no elevated position of the leg. No hot fomentations, no opiates were given, but the patient was ordered to force the exercise of the legs, just as soon as the clot

which formed was firmly fixed and the obstruction of the vein fully established, to rub into the leg freely (Metcalf's) lanolin and olive oil equal parts several times daily. When the pain of walking became excessive a temporary resting was indulged in by bending the leg upon the thigh, thereby compressing the arterial supply somewhat. A speedy complete recovery took place with no paralysis and no untoward symptom whatever, all existing oedema of the calf and ankle passing away at an early stage of the treatment. The theory is simple, that by these means the necessary collateral circulation around the obstructed vein was quickly formed by the tissues being softened and the pressure of the blood column remaining strong during the movements of the parts; opiates seem to be contraindicated where the tendency to stagnation of blood exists. Better is it to endure much pain than to risk adding to a disease. The patient can be seen by any one wishing to do so, and all inquiries will be gladly answered.

JOHN DIXWELL, M.D.

Deaths reported 1,941: under five years of age 688; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 344, consumption 276, lung diseases 242, diphtheria and croup 121, diarrhoeal diseases 77, measles 35, scarlet fever 29, typhoid fever 27, malarial fevers 24, cerebro-spinal meningitis 14, erysipelas six, puerperal fever five, whooping-cough one. From scarlet fever, New York 14, Boston five, Brooklyn four, District of Columbia two, Pittsburgh, Providence, Lowell, and Salem, one each. From typhoid fever, Boston six, Pittsburgh four, Brooklyn, Baltimore and Providence, three each, Portland, District of Columbia, Nashville, Lowell and Waltham one each. From malarial fever, Brooklyn and New Orleans seven each, New York six, District of Columbia one, Baltimore three. From cerebro-spinal meningitis, New York eight, Boston and Lowell two each, Nashville and Fall River one each. From

erysipelas, New York and Boston two each, Brooklyn and Worcester one each. From puerperal fever, New York two, Boston, Baltimore and Pittsburgh one each. From small-pox New York four, Brooklyn one. From whooping-cough, New York one.

In the 28 greater towns of England and Wales, with an estimated population of 9,245,000, for the week ending May 14th, the death-rate was 19.7. Deaths reported 3,494: infants under one year of age 818; measles 235, whooping-cough 136, scarlet fever 47, fever 33, diarrhoea 27, diphtheria 26.

The death-rates ranged from 18.7 in Bolton to 29.0 in Huddersfield; Birkenhead 19.8; Birmingham 22.6; Bradford 21.6; Halifax 18.4; Hull 17.2; Leeds 22.7; Leicester 14.9; Liverpool 26.9; London 17.3; Manchester 26.4; Newcastle-on-Tyne 26.2; Nottingham 21.6; Sheffield 20.5; Sunderland 15.3.

In Edinburgh 23.8; Glasgow 23.7; Dublin 24.4.

The meteorological record for the week ending May 28, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

	Barometer.	Thermometer.		Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 28, 1887, TO JUNE 3, 1887.

PERLEY, H. O., captain and assistant surgeon. Relieved from duty at Fort Maginnis, M. T., and ordered for temporary duty at Fort Snelling, Minn. S. O. 49, Department of Dakota, May 25, 1887.

SUTER, WM. N., first lieutenant and assistant surgeon (recently appointed). Ordered for temporary duty at Washington Barracks, D. C. S. O. 122, A. G. O., May 27, 1887.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING JUNE 4, 1887.

BRANSFORD, JOHN F., surgeon. Ordered to the Smithsonian Institution at Washington, D. C.

TRYON, RUFUS J., surgeon. Detached from the United States Steamship "Quinnebaug," and ordered home.

SIEGFELD, CHARLES A., surgeon. Ordered to the United States Steamship "Quinnebaug."

MARTIN, WILLIAM, assistant surgeon. Detached from the United States Steamship "Pinta," and ordered home.

FITTS, HENRY B., passed assistant surgeon. Detached from the Receiving Ship "Vermont," and ordered to the United States Steamship "Pinta."

FIELD, JAMES G., assistant surgeon. Ordered to the Receiving Ship "Vermont."

#### SOCIETY NOTICE.

NEW HAMPSHIRE MEDICAL SOCIETY.—The Ninety-Seventh Annual Meeting will convene in the Opera House, N. Main St., Concord, N.H., Tuesday, June 21, 1887, at 11 A.M. The programme for Tuesday, June 21st includes: (1) Annual Address by the President at 12 o'clock. (2) "Obstetrics: Thirty Years' Experience in a Country Practice," by Dr. William Child, of New Hampton; discussion will be opened by Dr. J. W. Parsons, of Portsmouth. (3) Oration: "Homoeopathy," by Dr. George H. Sanborn, of Henniker; discussion opened by Dr. I. G. Hill, of Dover. (4) "Newmarket's Epidemic of Diphtheria in 1885 and 1886," by Dr. Charles A. Morse, of Newmarket; discussion opened by Dr. I. A. Watson, of Concord. (5) "Laceration of the Perineum," by Dr. F. B. Perkins, of Londonderry; discussion will be opened by Dr. S. C. Whittier, of Portsmouth. (6) "Report on Therapeutics," by Dr. Luther Pattee, of Manchester; discussion opened by Dr. C. E. Nichols, of Franklin Falls. (7) "Report on Surgery," by Dr. J. H. Cutler, of Peterborough; discussion opened by Dr. W. T. Smith, of Hanover. (8) "Dissertation: The Confidence of the Public in Non-Professional Prescriptions," by Dr. W. S. Leonard, of Hinsdale; discussion opened by Dr. William Child, of New Hampton. (9) "Report on Neurology," by Dr. J. J. Berry, of Portsmouth.

#### OBITUARY.

MARCUS BLOOMFIELD LEONARD, M.D., M.M.S.S.

The death of this gentleman, already noticed in our columns, removed a practitioner of over thirty years' standing in East Boston. Dr. Leonard was a native of Sugar Grove, Pa. He attended the Albany Medical College, and in 1846 came to Cam-

bridge to study at Harvard College. He attended lectures by Dr. Channing, Dr. Oliver Wendell Holmes, and graduated in the class with Dr. William H. Thordike, in 1849. He practised for a time in Worcester, but afterward came to East Boston, where he settled and has since resided. Dr. Leonard was a member of the Massachusetts Medical Society, and was also prominently identified with the Citizens' Trade Association of East Boston.

#### BOOKS AND PAMPHLETS RECEIVED.

Annual Announcement of Dartmouth Medical College. 1887. Transactions of the Rhode Island Medical Society. Vol. III. —Part IV. 1886.

Annual Announcement of the Buffalo College of Pharmacy for the Session of 1887-88.

Case of Herpes Omo-Brachialis. By James I. Tucker, A.M., M.D. Chicago, 1887. (Reprint.)

Feeding Patients against the Appetite. By Ephraim Cutter, M.D. New York: W. A. Kelloge, 1887. (Reprint.)

A Statistical Contribution and a Comparison of Methods in the Treatment of Tuberculosis of the Joints. 1886. (Reprint.)

Dermatitis Venenata: An Account of the Action of External Irritants upon the Skin. By James C. White, M.D. Boston: Cupples & Hurd, 1887.

Seventeenth Annual Report of the Massachusetts Homoeopathic Hospital, and of the Ladies' Aid Association, for the Year ending December 31, 1886.

The Veterinary Service of the United States Army. By R. W. Shufeldt, M.D., C. M. Z. S., etc. Captain, Medical Department U. S. Army. 1887. (Reprint.)

Complimentary Banquet to H. H. Hill, M.D., given at the Augusta House, Tuesday, June 15, 1886. It being the Fiftieth Anniversary of His Continuous Practice of the Medical Profession. Augusta, Me., 1887.

Oration delivered before the Alumni Association of the Medical-Chirurgical College of Philadelphia, on the Evening of Thursday, April 7, 1887. By Dudley S. Reynolds, A.M., M.D., Louisville, Ky., 1887. (Reprint.)

The Scientific Rationale of Electrotherapy. A Revised Paper on the Therapeutic Applications of Electricity. By C. H. Hughes, M.D., St. Louis, Lecturer on Neurology and Electrotherapy, St. Louis Medical College, etc. (Reprint.)

The Gathering of the Waters: or the Evolutions of Seas and Rivers. By D. T. Smith, M.D., Lecturer on Medical Jurisprudence in the University of Louisville, and one of the Editors of the Practitioner and News. Louisville, 1887. (Reprint.)

The Importance of Instruction in First Aid to the Injured. By W. Thornton Parker, M.D. (Munich), of Newport, R.I., late A. A. Surgeon U. S. Army; Member of the St. John's Ambulance Association, England. Chicago, 1887. (Reprint.)

The Scientific Rationale of Electrotherapy. A Revised Paper on the Therapeutic Applications of Electricity. By C. H. Hughes, M.D., St. Louis, Lecturer on Neurology and Electrotherapy, St. Louis Medical College, etc. 1887. (Reprint.)

The Progress and Limitations of Operations upon the Abdominal Cavity. By J. Ewing Mearns, M.D., Lecturer on Practical Surgery in Jefferson Medical College; Gynecologist to Jefferson Medical College Hospital; Surgeon to St. Mary's Hospital, etc. Being the Annual Address delivered before the Philadelphia Academy of Surgery, March 7, 1887. (Reprint.)

### Lecture.

#### THE POSITION OF THE MASSACHUSETTS MEDICAL SOCIETY; ITS RELATIONS TO MEDICAL PROGRESS, TO THE COMMUNITY IN WHICH WE PRACTISE, AND TO ITS FELLOWS.<sup>1</sup>

BY GEORGE J. TOWNSEND, M.D., OF NATICK, MASS.

In obstetrics, the progress which has been made is well marked, and the change in method, in many respects, is well-nigh radical.

In our student days, we were counselled never to carry a pair of forceps with us to a case of labor; in fact, it was considered better that we should not even own a pair. This was to discourage what is called meddling midwifery, as objectionable now as it ever could have been. Yet those of us who have been called, as a last resort, to a patient worn out by days and nights of fruitless effort, and, after a successful delivery with forceps, have seen her succumb, plainly from exhausted vitality, can best realize the danger of a do-nothing policy.

Indiscriminate haste in interference with nature's processes is fraught with evil consequences, often entailing permanent disabilities, while too long delay in affording necessary aid is fatal in its effects.

The happy medium is now inculcated by our teachers, and ably carried out by our Fellows, so that we may reasonably hope that mothers undergo their severest ordeal with a minimum of danger and suffering.

Continued efforts are still made to perfect instruments; but however desirable it may be to have a pair of forceps perfectly adapted to their ends, we should not be allowed to lose sight of the fact that it is of much greater importance that the hand which uses them should be guided by a calm, dispassionate brain, and should be practised and skilled for its work.

In a well directed effort to avert the necessity of a resort to the most repulsive operation in difficult labor, craniotomy, one of our most progressive teachers has most persistently and ably advocated version where forceps have failed. This is a procedure dangerous enough to mother and child, and not lightly to be adopted. Yet it is demonstrable that it often will succeed in safely delivering the mother and saving the life of the child. Should it fail, the dread alternative is still practicable.

In no disease has there greater progress been made, in pathology and treatment, than in that most dread complication of the parturient state, puerperal, now known as septic fever. Less than fifty years ago this disease was accepted as an idiopathic fever, essentially consisting in peritoneal inflammation and not necessarily contagious. The treatment which we were taught in our student days, corresponded with this pathological view, copious blood-letting being the first requisite, the sheet anchor.

Very soon the occurrence of frequent consecutive cases in the practice of one physician after another, attracted attention, and an invaluable paper maintaining its contagiousness was published by a Fellow of this Society; who amongst the flattering homage of the whole literary world, has his crowning glory from our standpoint, in his well-earned reputation as the "faithful teacher." This paper is believed to be the first conclusive argument which had then been pub-

lished proving the fact, that the disease could be, and had been carried from one patient to another by the attending physician. After its perusal, no one could go from a case of puerperal fever, to attend a case of labor, without an inward consciousness, at least, of criminal carelessness.

It was reserved for more recent investigations, to show upon what this contagion depends, and how the hand which is used to comfort and assist becomes the vehicle of death.

Whether or no the germ origin of disease be yet accepted in its entirety, the results obtained by the systematic and rigid application of antiseptics before, during, and after labor, in abridging the frequency of the disease and diminishing its fatality, are simply astounding, and though in the present state of our knowledge we may not hope to see it entirely stamped out, the fact that we can render its occurrence infrequent and that we can abridge its mortality by means within the reach of every practitioner, will enable us all to breathe a sigh of relief.

The convincing incontrovertible paper prepared with most exhaustive care, the result of most exact observations, just published by the senior attendant of our "Lying-in Hospital," a paper which it would be well were it emblazoned in letters of gold and sowed broadcast throughout the ranks of our profession, leaves no longer room for doubt that the disease is the result of septic infection, introduced from without, that germicidal precautions and treatment will prevent its introduction and will modify its consequences when it has occurred.

In the outlying districts of our Society puerperal septicemia is a rare disease. The seed to be developed must fall upon good ground. The more robust frames, the purer air, the simpler habits of life obtaining in those districts are all-important factors conducing to this end. But when it does occur, there is nothing in the whole category of disease more appalling, as all of us can realize, who, after leaving a newly-made mother, safely conducted through her dreaded ordeal, happy in the joys of maternity, have been hastily summoned to her bedside, by the onset of that dreaded rigor, too often the precursor of the final chill of death.

It is now but little more than twenty years since antiseptics was first suggested, and it was at once readily adopted, more especially by our surgeons, its methods carefully studied, its details minutely described and faithfully carried out. An able and earnest plea for its general reception has been made from this platform. Its wonderful results speak for themselves, limiting contagious disease to the individual in which it arises, arresting the progress of epidemics, and rendering practicable operations in surgery, previously regarded as formidable, as they were unsatisfactory in their termination.

In abdominal surgery its value is most readily noticeable. Witness the long list of ovariectomies, without a failure, in the practice of our most distinguished specialists, with a host of other triumphs in general, as well as in abdominal surgery.

There has been a difference of opinion as to the manner in which it acts in preventing disease, and it has been maintained by many that it is essentially only that cleanliness which is akin to godliness. Yet in view of recent developments, antiseptics is generally recognized as, not only the prevention of the presence

<sup>1</sup> Concluded from page 543.

of germs in abraded surfaces, but also the employment of germicides to render them inert should they escape our vigilance.

Its use is now by no means confined to our cities; though the denser the population the more necessary it is to guard against the communication of disease. In the remotest regions it is now habitually employed, and the country physician's satchel is rarely found without a supply of the bichloride, a box of antiseptic unguent, and a nail-brush.

The exclusive use of germicides, in the treatment of all disease, and its triumphant success in arresting morbid processes, is probably a therapeutic Millenium we may never see. For granting that every disease has its specific bacillus the killing of which will arrest the disease, a germicidal agent powerful enough, for that end, would be equally destructive to the organism in which the germ occurs. Yet a growing tendency to the employment of germicidal therapeutics is already noticeable, and the apparent results obtained promise a radical improvement in the treatment of many, especially the zymotic diseases.

We have admitted woman to fellowship in our Society.

Fully realizing the force of the objections urged against this, by many of our most experienced and able Fellows, not believing now, that numerically, she will ever become a large factor in the practice of medicine, we were early confronted with the fact that we had amongst us, conscientious, educated, competent female practitioners, and that they had become such without abating one jot or one tittle of those characteristic, inherent, feminine qualities, which constitute woman's priceless jewels. In the most dignified manner, with the utmost propriety, she asked permission to appear before our censors for examination, that, if found qualified, she might be admitted to our Society, shrinking from no ordeal, however severe, that they might deem necessary to prove her acquirements.

It would seem then that we owed it to our manhood, to our simple sense of justice, to grant her request, and by setting the seal of the Society's approval upon the successful candidates, to enable the public to discriminate between them, and a host of others, amongst whom may be those who are uneducated, unscrupulous, not to say profligate.

There are certain positions which a competent female practitioner, who is also a true woman, is peculiarly adapted to fill and in which her power for good is necessarily greater than that of any man can be. As an evidence of this fact, the good work of the late physician and afterward superintendent of our Female Reformatory Prison, is especially prominent. Her fostering care of the unfortunates committed to her charge and her humanizing influence upon them cannot be overestimated, and we have every reason to believe that the good seed so faithfully sown will bring forth lasting fruits, fraught with good results to the whole community.

But for an accidental circumstance she would probably have become the first female Fellow of our Society, and though now transferred to another more congenial and not less useful sphere, we can but regret her loss to our State.

For similar reasons there is another position which a competent female practitioner is peculiarly adapted to fill, that is, the medical supervision of the female wards of insane asylums, where a large proportion of

the cases, as large as one-tenth, if I am rightly informed, are erotic in their type, rendering the very presence of the opposite sex objectionable. The experiment has certainly been tried with success in a neighboring city.

Our good State enjoys the unenviable distinction of being the paradise of empirics. Aroused by the lamentable consequences of malpractice, resulting in one not very remote instance in the death of the victim and a verdict of manslaughter against his slayer, our Society appointed a committee to procure legislation regulating the practice of medicine. Mainly through the efforts of its indefatigable Secretary a bill for that end was framed and introduced into the Legislature, there to be killed by the strenuous efforts of its interested antagonists, aided by able counsel, and well supplied with the sinews of war. This is perhaps well, after all; for though our State is in a small minority, some twenty-six of our neighbors having enacted such a statute, and individuals must still suffer from maltreatment, the true method of overcoming empiricism, is by demonstrating to the public that only treatment by an educated skilled physician can produce the result most to be desired, the speediest possible restoration to health and usefulness. But by making this move we have at least shown our unselfish desire to promote the welfare of suffering humanity. For, had the bill become a law, in no possible sense could we personally have been benefited by it as not seldom our most profitable practice is in undoing the mischief which empirics have caused.

Brethren, the object of this superficial, imperfect sketch, for the half has not been told, is not mutual felicitation. We have sought only to adduce evidence enough to show beyond the possibility of doubt, that, while many of our master minds have originated improvements which constitute eras in medicine and surgery, the Fellows of our Society in general, each one according to his opportunity, have ever been found in the most advanced ranks of medical progress, abreast of its foremost wave.

The relations of our Society to the community in which we practice constitute a subject much misunderstood, yet of vital importance to our patients as well as of interest to ourselves. We have pledged ourselves to unselfishly give them the benefit of the latest researches, the most advanced thought in medical science, considering their welfare of the first, our own interests of secondary importance. We ask of them in return such reasonable compensation as may enable us to gain our daily bread, and we waive even that, in a host of cases where necessity and destitution may require it. This gratuitous practice necessitates more or less self-sacrifice, for though some of our Fellows are blessed with an abundance of this world's goods, if our professional income were divided up there would barely be enough to go round. And while this fact obtains, many an unblushing empiric acquires a large fortune. For as one of our eminent teachers once said to me, "that physician is a fool, who, if he has no principle cannot make money."

The tendency of many patients to frequently change from one physician to another, is one great obstacle to the systematic and effectual treatment of their cases; an obstacle of more moment to the sufferer than his physician. For though it is by no means flattering to our self-esteem, after we have carried a case through its gravest phases to have it suddenly taken from us

and placed in the hands of some pretentious pathist, who readily asserts that the patient would have saved much time and suffering if he had only been called sooner, in the long run more patients will come to us under similar circumstances than will leave us.

We value our regular families who for one or two generations perhaps always depend upon us for aid in their hour of need, not because we are sure of their patronage and for the liberal fees which await us when our services are rendered and our attendance ceases; not because of the friendships which, however much the idea may have been depreciated in some quarters will spring up and abide between physician and patient; but because, familiar with their surroundings, their habits of life, their idiosyncrasies, we can render them more intelligent and efficient assistance. No physician, however familiar from long practice with the treatment of disease, can afford to lose sight of the weight of responsibility that rests upon him in the management of every grave case in which the issue of life or death depends upon his fidelity, judgment and ability. Any circumstance that will lighten that burden and make the successful issue more sure is of vast importance and is eagerly sought for by us all.

The causes of this tendency in the community are various. Success being naturally the touchstone, by which a physician's ability is tried, the occurrence of one fatal case after another, in spite of his most able and earnest efforts, often drives relatives to seek any change which promises better results, forgetful of the fact that one such disease awaits us all, no human power availing to ward it off.

Impatience of suffering and delay, a constant search after something new — the characteristic of our nation — misleading statistics, loud pretensions of superior methods, of new means, natural and supernatural, all are factors tending to this result, only to be combatted by a diffusion of the knowledge of the true powers and scope of medicine. There is one cause over which we have some control, and the influence of which we can diminish, and that is the too flippant use of the word *cure* — a word which, in its sense of restoration to health, it would be well were it eliminated from medical phraseology, and the fact stated that no patient was ever yet cured of any disease or disability by any medication or surgical operation. Medicine arrests pathological changes, abates symptoms, relieves suffering. Surgery removes foreign growths, adjusts displaced and fractured members, and, after all, in many instances, the patient fails to get well. Take any familiar disease, for instance, say diphtheria: many at first uncompromising cases recover, while another, in which the disease seems to have been overcome, the membrane disappears, the appetite returns, fails to do well, and finally succumbs.

So in ovariectomy, a most unpromising case, with extensive adhesions and other grave complications, gets well, while another, in which everything seems favorable for a successful operation, dies.

This, eliminating that general depressing effect of disease and operations, which is termed shock, is from a deficiency of a certain unknown quantity, which we have but limited means of estimating, and over which we have but little control, and which we call constitution, vitality. Whether this be a distinct principle, implanted in the economy with the breath of life, and growing with its growth, or the aggregate of the inherent

forces of organized matter, as has been ably maintained for and against, within our Society, is of no moment. The final cause is the same: the strength of that principle, the sum of those forces, determines the issue in every case.

The relations of our Society to other physicians in the community seems to constitute a topic which is to be treated very gingerly, and with great caution, for what reason is not apparent, unless, forsooth, because many of them with good social standing have a greater or less following of people intelligent and educated enough in other matters, but lamentably ignorant of the true scope and powers of medicine.

Under our by-laws, we can simply have no professional relations whatsoever with such practitioners, neither in general, in special, nor in hospital practice. In general practice, the language of our by-laws is explicit enough, and it makes no exceptions for special nor for hospital practice. In fact, the attempt of any Fellow of our Society to treat a special organ, while some pathist manages the rest of the system, would be a manifest absurdity. What, for instance, could an oculist do with the specific forms of iritis, while somebody else dealt with the systemic infection?

If, in hospital practice, the wards are kept distinct, there is nothing in our by-laws which forbids our Fellows taking charge of one part of a hospital, while some other physicians take charge of another part. But if the rules of such a hospital require, at any time, a consultation between the members of the different staffs, medical or surgical, no Fellow of our Society can consent to such a consultation without plainly violating his written assent to our by-laws, and imperiling his affiliation to the Society.

Our by-laws forbid such consultations, for good and sufficient reasons obvious enough to any unbiased inquirer, as it is impossible that any benefit could accrue from them, either to the patient, to medical science, or to the consultants. There can be nothing in common between two physicians, of whom the one, fitted by his experience and studies to cull from the broad domain of medical science all the facts which may throw light upon a given case, bases his diagnosis upon those facts, and shapes his treatment accordingly; while the other, having an exclusive theory to maintain, in all consistency, can only accept such facts as accord with his theory, and must reject or ignore all others.

What benefit could the patient derive from such a consultation? No argument is possible between the physicians, and neither of them can conscientiously yield his views. The patient has no new light thrown upon his case which his attendant accepts, no new treatment proposed which he can carry out.

Nothing is gained for medical science; for the more a case is discussed from such opposite standpoints, the wider the difference grows, until the consultants separate with a mutual feeling of dissatisfaction, if not of hostility.

What becomes of our boasted philanthropy when we decline such consultations, and refuse the benefit of our advice to a sufferer? We do not decline to aid any sufferer, as far as our time and strength will allow; but, as the responsibility of life rests upon us, we only ask that we shall meet one who is willing to see the force of our reasoning, and, assenting to it, will faithfully carry out our suggestions.

We have expelled from our Society, Fellows who

profess to cure diseases by any exclusive method, any pathy, and a howl of indignation at our uncharitableness and illiberality echoed from one end of the State to the other, which was as unreasonable as it was uncalled for: uncalled for, because we have ample and unquestionable authority to manage our own affairs, to establish our own by-laws and enforce obedience to them without outside interference or criticism; unreasonable, because the main point at issue has been either entirely misunderstood or wilfully ignored. Submission to the will of the majority is the cardinal principle of every organization in a republican government, without which there can be no permanency nor power in it, and our own affords no exception to the rule.

We have adopted a certain standard for ourselves; we are incorporated for certain definite purposes; we have established by-laws to enable us to carry out those purposes; we have provided a way to change those by-laws from time to time as expediency may dictate; we require all Fellows to comply with them, and we allow any Fellow to sever his connection with the Society, at his own will and pleasure, provided only that he has paid his dues and has made a written application giving his reasons therefor. When a Fellow openly and avowedly violates our by-laws with which he has agreed in writing to comply, and he becomes guilty of practices forbidden to Fellows, his conduct viewed by any standard of honor and probity, is unworthy an honorable physician and Fellow of this Society. It is simply giving the lie to his written promise. For this, because they deliberately violated their written word and sought to weaken and subvert an institution which they had promised to sustain, have Fellows been brought to trial, and when found guilty have been expelled from the Society; and not from any personal nor professional hostility to them. No other course was possible consistent with our self-respect and our regard for the permanency and influence of our Society.

Other physicians viewing these objects from a different standpoint, have organized societies professing certain methods of treatment and practising more or less consistently, according to those methods. With these we have no concern. We have no right even if we have the inclination to criticize them, much less to assert that they are dishonorable or unworthy practitioners. Our professional differences are irreconcilable, but there need be no personal nor social antagonism between us, any more than between others who hold opposite opinions upon various subjects.

The relations of our Society to its Fellows comprehend our mutual relations to each other. Our first duty, if we wish to promote the integrity and influence of our Society, is to guard well its portals, to see that none but good men and true enter there. The committee, appointed by our councillors, have with much labor prepared an exhaustive list of medical schools, which have given evidence of honest, faithful work in fitting students for our profession, and this list has been accepted by the council. A diploma from one of these schools, or its equivalent, is a prerequisite to an examination for fellowship required from every candidate. Yet there are Fellows of our Society to-day by no means necessarily incompetent physicians nor is the date of their admission remote who cannot show such a diploma or its equivalent. This is an evidence of laxity in discharging their duty

on the part of the censors who passed them, plainly forbidden by our by-laws. Though our Society thus far may have suffered no detriment from this, a continuance of the practice is clearly an injustice to those candidates who have complied with our requirements, and opens the door to others in the future who may be anything but desirable Fellows.

Once admitted to our Society we cannot sever the affiliation of any Fellow without preferring charges against him, and giving him a fair trial, in which he has an opportunity to explain and refute those charges. It is evident that it would not be an easy matter to convict one of a violation of the by-laws of our Society before he had given his assent to them, and it would necessarily appear that the fault should be laid at the door of the censors and not of the candidate.

Until quite recently there has been no attempt to secure anything like uniformity in the examinations by the censors of our different districts, and instances are not wanting where candidates rejected in one district have, after the prescribed time has elapsed, applied in another, with the hope of receiving an easier examination. The recent move by the censors to establish a definite system of examination throughout all our districts, is in the right direction, securing a practical, honest test of his acquirements to the candidate, one which every practitioner ought to be able to pass, and excluding only those who are clearly deficient in education and therefore incompetent.

One more topic I fear would not pass over, albeit a delicate one. Our organization is essentially a brotherhood. We are banded together for the public weal. Harmony and unanimity are necessary to the attainment of our ends. In the active competition of professional life, a competition which with many of us means a struggle for daily bread, collisions may occur, always fostered and enjoyed by outside parties ever ready to cavil at our profession, the evil effects of which are only to be averted by mutual concession and forbearance. Sharp criticism, disparaging remarks concerning a brother physician, are often thought to be sweet incense to our ears, whereas a greater insult cannot be offered us or our profession. It is rarely, indeed, the case that we cannot offset such remarks by the mention of some act of unselfish and successful devotion on the part of our abused brother.

We have admitted women to our Society. We all recognize her priceless influence in softening the asperities and promoting the amenities of social life, may we not hope for some of that same influence in our professional relations, so that when we are tauntingly asked, when doctors disagree who shall decide? we may answer, the woman.

Brethren, let us close our ranks, progress shoulder to shoulder, banish all personal animosities, do battle only against the King of Terrors and all his attendant miseries, and, though worsted at last in every encounter, with services often unrequited and even unrecognized, gathering consolation in that we have contributed our mite to diminish the sum of human suffering.

Thus may we expect to see our Society acknowledged as the power for good in the community, which it is; commanding the respect which is its due, because founded upon eternal principles of truth and benevolence.

A CASE OF ANEURISM OF THE ABDOMINAL AORTA.<sup>1</sup>

BY ISRAEL T. DANA, M.D., PORTLAND, ME.

On the 6th of August, 1886, I was called to Naples, Me., to see Mr. A—H—, in consultation with Dr. John Y. Lord, of that town. Dr. Lord told me the patient had been under his care for a few weeks only; that he had been employed for years in the Cumberland Paper Mills; that his health had been gradually failing for a year or two, till now he was utterly incapacitated from all labor; that he suffered from beating and throbbing about the chest and stomach, dyspepsia, and great nervous disturbance and prostration; while the nature of the case remained obscure.

I found the patient presenting the general and local symptoms mentioned. Age thirty: of previous robust health, and great powers of endurance, having been famous for his long walks through the woods; had had most of the diseases of childhood, and also typhoid fever; maternal grandmother had died of consumption, and his father of heart disease.

He was emaciated, feeble and anæmic; his weight had become reduced from a hundred and seventy-two (estimated) to a hundred and twenty pounds; his stomach was sensitive, his digestion weak, and his pulse very frequent, unsteady, and irritable.

The most prominent subjective symptom was a constant sensation of beating and pulsation in and about the epigastrium. This, while constant, was subject to paroxysmal aggravations, easily induced by mental excitement or physical exertion, and sometimes related, he thought, to gastric derangements. The beating and pulsation were sometimes so pronounced that his wife said "it made her nervous to lie near him in bed." He suffered a good deal from thirst, and from sensations of heat and burning in the epigastric region, with more or less of associated soreness and tenderness. Of late these sensations had seemed to reach lower down, nearly to the level of the umbilicus. At times in rubbing over this region with his hand he would find the tender area to be scarcely larger than a silver dollar. He was subject also to sensations of sinking and faintness referable to the epigastric region. He had never had any fixed vertebral pain of the so-called "erosive" sort, but had had a good deal of pain of a neuralgic character, radiating from the epigastrium, and varying greatly both in intensity and extent.

He gave the following history. In August, 1884, while at work in the paper-mills, he was descending in a friction-elevator containing also a ton of paper. A man who was with him pulled by mistake a rope, removing the friction, and the elevator fell heavily to the floor below, a distance of ten feet. Mr. H. struck forcibly on the small of his back upon a narrow rail, across which his body was balanced. He was conscious of being badly bruised, and felt very sore at the point of the blow both internally and externally, but did not entirely give up work at the time. This remained a permanently weak point growing steadily more and more troublesome. As the months rolled on he observed that his powers of endurance were

waning, and he would get out of breath more easily. His wife also observed that he would get tired quickly, and then would have a feeble and distressed look. He would feel tired first at the very spot of the injury. Though gradually failing he did not give up work altogether till June 25, 1886, when he left the mill and went with his wife to her father's house in Naples.

On examination of the abdomen anteriorly, patient lying upon his back with limbs drawn up and supported, I found, through the thin walls, just above the level of the umbilicus and a little to the left of the middle line, a small roundish expansile tumor, not quite so large as a pullet's egg. Taking it between my fingers of both hands I recognized the fact that the expansion was equable. There was a single impulse related to the cardiac ventricular systole. There was no back-stroke. There was also a distinct blowing sound audible through the stethoscope *gently* pressed upon the tumor. Percussion signs, owing to the rather small size and peculiar surroundings of the tumor, were rather vague.

On examination posteriorly, patient in sitting posture, I found a perfectly distinct independent centre of sound and pulsation, near the level of the twelfth dorsal vertebra. The sound was a double one and rhythmically related to the cardiac double sound. It was as if a miniature heart were there. The sounds were as distinct as those heard over the precordial region. Indeed they seemed sharper, and more intense, and the "booming" quality was pronounced. The area over which the sounds were so distinctly heard was sharply defined, and so limited as to be mainly included within the circumference of the trumpet-end of my stethoscope. Moving the ear upward along the back these sounds grew gradually fainter till entirely lost, the true cardiac sounds were faintly audible in the lower left intra-scapular region, and between these two centres of sound there intervened a region of silence. When I explained the case to the patient he said he had himself become conscious, within a few weeks, of the fact of a new centre of pulsation at the point indicated.

The *diagnosis* was clear. There was a small aneurism of the aorta just at its passage through the diaphragm. It was of traumatic origin. It seemed probable also that secondary inflammatory and possibly degenerative changes had involved the aortic coats higher up than the seat of the aneurism. Possibly some of the phenomena were due to pressure upon the solar plexus or splanchnic nerves.

My *prognosis* was guarded, and on the whole unfavorable. Some relief was however looked for, and in view of the remarkably favorable results, in cases lately reported, from the Bellingham-Tuffnell plan of treatment, some hope was encouraged of at least partial cure.

For *treatment* I advised (1) rest in bed, as nearly as possible absolute, to be maintained for perhaps two months, aconite and belladonna being used, *pro re nata*, for the heat and the irritability of heart-action; (2) a diet of bread and meat, with cocoa, milk or tea, the total of solids to be ten ounces, and of liquids eight ounces per diem; (3) iodide of potassium, in doses of twenty grains, three or four times a day, as best borne. The plan went into immediate operation with the exception of the rigid diet part, which the patient, as I afterwards learned from Dr. Lord, was very unwilling to submit to. In view of this unwillingness, and of

<sup>1</sup> Reported at the annual meeting of the Association of American Physicians, June 2, 1887, at Washington, D. C.

the fact of the immediate and progressive improvement without it, it was not later enforced.

September 1, 1886, Dr. Lord wrote me, "our patient is improving steadily every day. The motion in the abdomen is hardly felt. The pulse has fallen to a hundred. His appetite is reasonably good and nothing which he eats seems to hurt him. He has rested well nights, and in fact has been comparatively comfortable. He is gaining some flesh." Under date of January 27, 1887, he wrote again as follows: "after two months of rest in bed, he began to sit up a little, and gradually resumed moderate exercise by walking. About the middle of November he began to ride out. I think he has gained twenty-five pounds of flesh. He has taken the iodide of potassium all the time with occasional omissions of a day or two. He says he feels so much better while taking it he is unwilling to leave it off." Later reports were in the same strain.

On the 10th of May, 1887, I saw him again at Cumberland Mills, to which village he had returned. His wife said he had been so much better, and was feeling so down-hearted at being so long idle, he had commenced the day before to do a little light work at the mills. His work consisted in watching the paper as it moved by him at a given point, and removing any soiled sheets. There was no lifting or other heavy work, and sometimes there would be nothing to do for twenty minutes at a time. I was waiting at his house for him when he came home to dinner. His wife was with him and he had been walking perhaps the sixteenth of a mile. He was slightly out of breath with the effort of walking, and remarked that the mere announcement that I had come out to see him, though he was glad to see me, had made his heart palpitate. His weight was a hundred and fifty-one pounds; pulse a hundred, even, and fairly strong; tongue clean and appetite good. He was somewhat anemic, his nerves were easily disturbed, he was slightly dyspnoic on moderate effort, and palpitation was easily induced, but he had greatly improved since my first visit to him.

He gave the following account of himself. After my visit of August 1st, he had staid in bed for two months. In about three days after beginning the treatment the thirst and burning at the epigastrium suddenly left him. In October, when he began to get up, the heating and palpitation were greatly reduced. Since then they had largely subsided till now most of the time he does not notice them at all. He said that he was entirely free from them for weeks in the early winter, till in January he was thrown from a sleigh, after which he suffered more or less from them for several weeks. Exertion, excitement, or worry brings them on slightly. They have from the first been worse on waking in the morning, and he has been most free from them in the evening. Even within a few days, while considering the question of resuming work, he has had to sit up in bed, on waking, with heart-beating. The throbbing and tenderness, which he used to feel at the site of the aneurism, are only rarely and slightly felt now. Sometimes these sensations seem to him as if moved a little higher up, but his fingers recognize the aneurismal mass in the old spot. When he began to get up after his bed-rest, he could not at first bend directly forward to pick up anything from the floor, but had to get at it sideways. Now he can pick anything up naturally. He says he little thought at one time he should ever be as well as he now

is. He called my attention to two swellings at the base of the neck one on each side, just above the clavicles and near their sternal ends. His wife said if he gets cold and coughs hard, they swell to be as large as half-hen's eggs. They appear like sacular dilatations of the jugular veins.

On examination anteriorly, the aneurismal mass was found *in situ*, and not increased in size, while both impulse and expansion were diminished, and the blowing sound was but faintly recognizable through the stethoscope. On examination posteriorly, the independent centre of pulsation and double sound was found as before, but both motion and sound were greatly reduced in amount, and the "booming" quality of the sound was gone.

My conclusion as to the present condition is that a partial cure of the aneurism has been effected, the sac having been in large measure filled up with concentric layers of fibrine; also, that an inflammation which probably involved the walls of the aorta higher up than the level of the aneurism, has been largely or wholly reduced. The condition of the patient is therefore immensely improved.

My estimate of the chances of final and permanent recovery is not very hopeful. If the pecuniary circumstances of the patient were more favorable to rest of body and tranquility of mind; if he could live without either working or worrying about the support of himself and his family; and if he could have such recreation and change of scene as he might fancy, the prospect would be improved. But with all such conditions at the best, I should still make a very guarded prognosis. There are too many unfavorable liabilities. Embolism may easily occur; or suppurative inflammation may arise in the walls of the sac inducing pyæmia; or atheromatous degeneration may supervene, invading the aortic coats higher up which have already been the seat of inflammation; or in some other way, more or less direct, the aneurism may yet prove fatal.

#### WAS IT BERI-BERI?

BY G. B. STEVENS, M.D., GLOUCESTER.

On May 13th, I visited at his home in this city the mate of the barque *Charles G. Rice*, which arrived in Boston the day previous from Manilla after a passage of one hundred and twenty days. He was perfectly well when he left the latter port; when about one month out he was taken with diarrhoea, having daily "nine to sixteen discharges of blood and slime." Great thirst began at this time, and continued for the rest of the passage. He drank very largely of the water caught from the ship's houses after rains, and polluted by "chicken dung and tobacco juice." After the diarrhoea had lasted for two months, he began to "feel tired in the calves of the legs"; three or four days later, that is, one month before arrival in Boston, he noticed, while sitting on the rail with his legs hanging, that the right leg below the knee was swollen. The left leg began to swell a few days later. One week before arriving in Boston the penis became edematous. The edema of the scrotum, which appeared three or four days later, would nearly disappear during each night. The diarrhoea had lasted up to this time, though during the latter part of the voyage the discharges averaged but two to four a day. This, he

thinks, may have been due to the better quality of the water, as they then used in part that stored in the butts. He never had any vomiting, but a disrelish for food, almost amounting to loathing. They had a plenty of fresh poultry, and canned food carried from the States a year and a half before. He did full duty until the last four days, and during that time did not give up entirely.

I saw the patient an hour or two after his arrival in this city. He was sitting up; through breathing his native air, perhaps, the anorexia of the sea-voyage had given place to a craving for food, and already preparations were making for the first meal in his old home to be of Gloucester's great food-product. He told me he had the "dropsical scurvy." This, he said, was the opinion of the captain, who had suffered similarly on a previous voyage, and at an English hospital this name had been given to the disorder. Looking for scurvy, I found no bleeding or sponginess of the gums, no ecchymoses in the cutaneous surface, no history of hæmorrhages excepting with the intestinal discharges. The dropsy, however, was evident enough. It was most noticeable below the trunk. The genitals were enormously swollen. The feet and legs were oedematous, pitting slightly on pressure. The left thigh was less swollen than the right. There was oedema over the pubes. The backs of the hands and wrists were somewhat puffy. The face appeared to be slightly swollen symmetrically, but there was no puffiness about the lids. I found no evidence of ascites, of pericardial or pleural effusion. The appearance of the face was that of plethora, and not of anemia. The pulse was between 90 and 100, and somewhat irregular. The tongue was clean and moist. The bowels were acting four or five times daily, and the impulse to relieve them came very suddenly, and had to be quickly responded to, or the discharge would be beyond control. The urine was scanty. Thirst was extreme, and the appetite had become great. He said he was "well all but the swelling," which was very inconvenient.

He was ordered to bed, allowed to satisfy his appetite at first, but told that it would soon be restricted.

On the day following he was put on a diet of milk porridge with bread, and ordered three times a day fifteen minims of tr. digitalis with potass. acet. and gin. Dover's powder was prescribed for the diarrhoea. The next day, the 15th, a specimen of the urine was examined: the color was dark; the reaction, strongly acid; the specific gravity, 1.015; no albumen was found. On the 17th, diuresis had begun, but was not continuous. A specimen of the urine examined was pale, acid in reaction, of the specific gravity of 1.014. No albumen was found, nor anything abnormal under the microscope. Half an ounce of the infusion of digitalis three times a day, and an infusion of broom-top were substituted for the diuretic mixture first ordered. The porridge, he thought, caused a feeling of fullness at the stomach, it was accordingly omitted, and milk, eggs, and bread allowed night and morning, with fish and bread at noon. The appetite was still very large; thirst was great. The discharges from the bowels were thin and somewhat bloody, but were less in number. On the 20th, the kidneys were acting with great energy, principally during the night. The oedema everywhere was much lessened. Pulse 72, full and regular. On the 21st, the oedema was to be seen only in the prepuce. The patient was sitting

up. The broom-top was omitted. On the 23d, the oedema was all gone. The appetite was more natural; thirst was less. The bowels were moving but twice or thrice daily; the discharges contained little blood. After the oedema had gone he complained of numbness in the legs, most marked below the knee, especially in the calves of the legs. Pinching or scratching the skin in this situation produced but little sensation. He never seemed to have noticed this on ship-board, and it certainly was not a symptom in the early part of the time he was under my care. On the 26th, the kidneys were acting freely, but not immoderately. Their secretion showed nothing abnormal. The digitalis was omitted, and fifteen minims of the tincture of the chloride of iron were ordered three times a day. The appetite was quite natural, and a more varied diet was allowed. The bowels were moving twice daily without blood. The patient walked out for the first time on this date, and was discharged.

The lax condition of the skin, even where the oedema had not been great, as, for example, about the hands and face, was very noticeable. A shrinkage, from a partial desiccation of the tissues through the large amount of water eliminated by the kidneys, seemed to have resulted. The patient said he had never been so thin. A pair of trousers, that fitted him four months before, were distended to their utmost when he reached home, and two weeks later they were loose almost to a ludicrous degree. He complained much of numbness of the legs. This seemed to have increased.

The case is not reported as positively one of beri-beri, but I think there is reason to believe it may have been. The dropsy was certainly of an uncommon form, and, in my opinion, was not traceable to the usual causes. On the other hand, the condition of the bowels was unlike that met with in most of the cases of beri-beri that I have read of; constipation has seemed to be the rule. The nervous symptoms, consisting only of impaired sensation in the lower extremities, were a late occurrence.

### Clinical Memorandum.

#### A CASE OF TOXIC SYMPTOMS ARISING FROM THE USE OF COCAINE.

BY EDWIN W. BULLOCK, M.D., HAVERHILL, MASS.

DURING the last few months I have used cocaine quite freely, especially for producing anaesthesia of mucous surfaces. Therefore, the following case of toxic effect from the drug after giving me considerable anxiety for the time being, has seemed to be sufficiently interesting and instructive to warrant my reporting it to the JOURNAL.

Sunday, May 15th, Mr. P., aged 24, came to my office to have tonsillotomy performed. In order to obtain anaesthesia, I employed first, a spray of a four per cent. solution of cocaine (Squibb's four per cent. solution with boric acid being the one used), then, by means of a sub-cutaneous syringe, made six injections of the same solution into the tonsils, at three different points in each.

About two drachms were used in the spray, and forty (40) minims was the whole amount injected. The operation was entirely successful, perfect anaesthesia being obtained and but very little blood lost. At 3 p. m., about four hours after the patient had left my

office, I was summoned in great haste to see him. It seems that about 2 p. m., he was suddenly seized with a very severe headache and vertigo, soon followed by a "burning sensation" in his stomach and nausea but no vomiting. His face became much flushed, respiration quite difficult, and finally delirium came on. When I first saw him he was tossing about in bed in a half-unconscious condition, muttering to himself. I was able without great difficulty to rouse him sufficiently to answer questions, after which he quickly relapsed into his former condition.

He complained of tingling sensations in the extremities, dryness and constriction of the throat, "burning sensation" in the stomach, nausea and intense headache. The pupils were widely dilated, there was some cyanosis of the face, but not of an extreme degree, respirations varied from ten to fourteen, pulse was 126 and very weak. I at once administered about  $\frac{z}{3}$  of brandy, and a few minutes later twenty drops of tincture of digitalis. This was vomited fifteen minutes later.

I then gave a sub-cutaneous injection of five grains of carbonate of ammonia, and applied hot sinapisms to the chest and epigastric region. A little later I again gave some brandy and digitalis, and this time it was retained. In about twenty minutes the pulse grew stronger, beating 115, and the respirations became less labored. I kept on administering brandy and digitalis at frequent intervals, and at 5 p. m., had the satisfaction of seeing the patient drop off into a quiet sleep. Pulse was 105 and quite strong, and respirations 18, while the cyanosis of the face had nearly disappeared. He slept quietly until 9 p. m., when he awoke and stated that he felt much better, but still had some headache. Pulse was 95, and respiration 20. He soon went to sleep again, and slept quietly the greater part of the night. The next morning, the 16th, he complained of a good deal of numbness and tingling in the extremities, intense dryness of the throat, and blurred vision. These symptoms gradually passed off during the day, and by night he was as well as before the attack. On looking up the subject of cocaine poisoning, as far as possible, I have been unable to find any case in which so long an interval occurred between the time of administration of the drug, and the first appearance of the toxic symptoms, nearly three hours intervening in this case.

Then too, the amount of drug absorbed was quite small, the patient only getting about a grain and a half by means of the injection; and allowing that one-half of the amount used as a spray was absorbed, about two-and-a-quarter grains from this source, making a total of three-and-three-quarters grains for the whole amount absorbed.

—Dr. Zschokke, of the University of Geneva, has been making some experiments on tænia, in the course of which he himself, with six students, who volunteered for the somewhat hazardous experiments, each swallowed five cysticerci. The results show the successful propagation of the tænia in every case, except that of one student, who was, at the time, undergoing a copaiba treatment.

—The newspapers report that W. Irving Bishop, the "mind reader," is suffering from a cataleptic attack which occurred last week.

## Reports of Societies.

### THE ONE HUNDRED AND SIXTH ANNUAL MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY, JUNE 7TH AND 8TH, 1887.

THE becoming harmony between nature and her devoted followers, the physicians of the State, was never better exemplified than in the physical environment of the one hundred and sixth annual meeting of the Massachusetts Medical Society, held in Boston on the 7th and 8th of June. The skies were fair, and the sun shone on both days; while, on the other hand, the attendance was good, the programme interesting, and the dinner and its succeeding exercises enjoyable. As of late years, the large hall of the Institute of Technology building was used for the literary exercises, and the dinner was served in the Clarendon Street Rink.

#### AT THE HOSPITALS.

The morning of the first day was devoted to hospital visits, the wards and amphitheatres of the two large hospitals, and of the Children's Hospital, affording, as usual, cases of medical and surgical interest.

At the City Hospital, the following operations were performed: Three cataracts removed by DR. H. W. WILLIAMS, by the Von Graefe method, with cocaine. DR. GAY opened an aneurism of the axillary artery, and ligatured the subclavian, and also did the following: amputation at the hip for hip disease, with extension into pelvis, previous excision; amputation at the hip for necrosis of the femur; imperforate anus; cancer of tongue and lower jaw, removal of anterior half of tongue and half the lower jaw. All instruments were kept in 1-40 carbolic acid, and the wounds were washed with the same. Iodoform and boracic gauze dressings were used.

In the amphitheatre of the Children's Hospital, DR. E. H. BRADFORD performed Kocher's operation upon an ankle of a boy of four, for the removal of carious astragalus; also MacEwen's operation for the radical cure of an indirect, reducible, inguinal hernia in a boy of ten. Several interesting cases were shown in the wards. A girl of thirteen was well of hip disease six years ago. The thigh was flexed upon the body at a right angle, because of bony ankylosis. The girl walked with marked deformity and limp. Six weeks ago, Dr. Bradford did an osteotomy upon the femur, just below the lesser trochanter. The deformity was almost corrected, and the case treated as a fracture of the femur high up. At present she walks with slight limp, the sole of her foot being but from one-half to one inch above the floor when she stands erect. Union at the point of fracture is complete. Two cases of empyema were shown: one a recovery after an incision high up, with resection of a bit of the rib; the other, in which an opening had been made high up, and pus evacuated. The sound was introduced and cut down upon when it reached the bottom of the chest, thus securing drainage and the possibility of free irrigation. Other cases were shown of wry-neck, treated by open incision, hip disease, spinal caries, club-feet, etc.

#### FIRST SESSION.

Shortly after two o'clock on Tuesday afternoon, the President of the Society, DR. THOMAS H. GAGE, of Worcester, called the assembled Fellows to order, and

the exercises were begun by the reading of the first paper, entitled,

#### TUMORS OF THE BLADDER,

by GEORGE W. DAVIS, M.D., of Holyoke.

Dr. Davis referred briefly to the methods of exploration of the bladder — by perineal section, by the supra-pubic operation, by bimanual palpation, and by the cystoscope and electric light — and then, after discussing the symptoms suggestive of a diagnosis of tumors of the bladder, proceeded to consider therapeutic measures. He took the ground that no cystic neoplasms, except of a syphilitic nature, could be affected by medicine, and advocated the treatment of symptoms, and the removal of the new growth when there was no special contraindication.

Dr. C. B. PORTER, of Boston, referred to a case of his own, where great suffering from vesical tenesmus and difficult micturition was completely relieved by the perineal operation, the patient ultimately succumbing to the disease. He inclined to the supra-pubic operation, as it was less dangerous, more easily done, and gave a better chance for exploration. In some cases a perineal exploration might first be made, but it was very difficult in stout subjects.

Dr. F. S. WATSON, of Boston, said that tumors of the bladder were not so rare as the brief mention in the text-books would lead one to presume. He favored the supra-pubic operation, and believed in operative measures, even when there was slight prospect of a cure.

Dr. JOHN HOMANS, of Boston, mentioned two cases where, in performing ovariectomy, he had accidentally cut into the bladder. In both cases the wound was sewn up, and healed without trouble.

The next paper was upon

#### CASES OF BURNS, WITH SPECIAL REFERENCE TO COMPLICATIONS, SEQUELÆ, AND TREATMENT.

by JAMES E. CLEAVES, M.D., of Medford.

The reader cited a series of cases from his practice, from which he derived a belief that treatment should be directed to the following ends: to relieve pain, overcome shock, support the strength, check granulations, aid healing by grafting, avoid cicatricial contraction, and overcome deformity.

Dr. G. E. FRANCIS, of Worcester, said that, from the first moment, every effort should be made to use antiseptic treatment. It was better to die from shock than undergo the torture of prolonged granulation, and suppuration could be prevented by complete antiseptics.

This was followed by a paper on

#### LAPAROTOMY FOR PUS IN THE ABDOMINAL CAVITY AND FOR PERITONITIS,

by JOHN C. IRISH, M.D., of Lowell.

The reader began by a discussion of the causes of pus within the abdominal cavity, illustrating his theme by cases under his care, and drew the conclusion that when there was pus within the peritoneum, the proper treatment consisted in incision, drainage, and antiseptics. In the case of perineal abscess, this would seem indisputable, and it was reasonable in acute general peritonitis, which rarely occurred without the effusion of a purulent fluid. Even in tubercular peritonitis, where, at first sight, incision would appear foolish, brilliant results had been attained; and in peritonitis

succeeding abortion, medical treatment was useless, and laparotomy might afford a chance.

Dr. JOHN HOMANS declared his belief that no abscess entered the pelvic cavity, except it entered from outside. Ovariectomies during peritonitis are usually successful. The procedure advocated by Dr. Irish was the only one possible. In peritonitis succeeding abortion, it was difficult, if not impossible, to effect a cure by any method.

The next paper was entitled

#### FRACTURE OF THE SPINE: ITS IMMEDIATE TREATMENT BY RECTIFICATION OF THE DEFORMITY AND FIXATION BY PLASTER-OF-PARIS JACKET,

by HERBERT L. BURRELL, M.D., of Boston.

Dr. Burrell suggested that there were but three methods of treatment of spinal fracture: the expectant (appropriate to a certain class of cases), the operative (condemned, except in gun-shot fractures), and reduction and fixation (which had yielded some good results). The reader illustrated his remarks by a series of tables compiled from all the cases that had occurred at the Boston City Hospital, and gave in detail two cases occurring in his service at the Hospital, in which he had successfully used the method of fixation [the patients were shown upon the platform]. He drew these conclusions: That rectification and immobilization was a rational method for many fractures of the spine; that almost any risk is justifiable under the circumstances; that if, as has been seen, softening of the cord may occur within forty-eight hours from pressure of fragments, treatment should be immediate; that suspension is but one means of rectification.

Dr. A. N. BLODGETT, of Boston, cited two cases within his own knowledge, and endorsed the views of the reader.

Then followed a paper entitled

#### OBSERVATIONS ON THE PUERPERAL PELVIC LIGAMENTS,

by STEPHEN W. DRIVER, M.D., of Cambridge.

Dr. Driver presented a series of statistics compiled from records of some three hundred cases in his own practice, from which it appeared that, in a large percentage of cases, there was an increase of about one-third of an inch in the pelvic diameters from the relaxation of the pelvic ligaments. From these observations, and from his subsequent study of the pelvis, he deduced the following conclusions: That the presence of the relaxation of the pelvic ligaments depends upon the constitution of the woman; that a certain degree of relaxation is normal; that there may be much relaxation with little lameness, and little relaxation with much lameness; that the lameness depends upon a pathological change; that a small degree, even, may facilitate delivery; that these conclusions may be invalidated by further observation.

Next came a paper upon

#### THE RELATION OF TEA DRINKING TO DISORDERS OF THE NERVOUS SYSTEM,

by WILLIAM N. BULLARD, M.D., of Boston.

This paper exhibited the results of the study of a series of dispensary cases, where the habitual use of tea to such a degree that it might be considered toxic, was evidently a large factor in the production of a variety of nervous symptoms, — palpitation, migraine, nervous irritability, paræsthesia, hysteria, mental asthenia, etc.

This was succeeded by a paper upon  
PULMONARY TUBERCULOSIS AS A SEQUEL TO ORDINARY PLEURISY WITH EFFUSION,

by HERMAN F. VICKERY, M.D., of Boston.

The object of the essay was to show the possibility of a pleurisy with serous effusion being clinically the first step towards consumption; or, in other words, that a man who has heretofore been apparently sound and falls ill with acute pleurisy, may be destined finally to succumb to pulmonary tuberculosis. The reader advocated this position by the citation of authorities and by the result of a series of cases under his observation, and drew the following practical conclusion: that in all cases of pleurisy with effusion, the patient is, long after apparent recovery, in danger of pulmonary tuberculosis, and demands all possible hygienic precautions.

The last paper on the programme,

THE SURGICAL TREATMENT OF CHRONIC EMPYEMAS, by MAURICE H. RICHARDSON, M.D., of Boston, was omitted on account of the unavoidable absence of the reader.

#### EXHIBIT.

At the adjacent building belonging to the Institute, there was held, under the direction of the committee of arrangements, an exhibition of official pharmaceutical preparations, instruments, surgical appliances and apparatus. It was unusually varied, well arranged, and interesting, including a large display of instruments, and several invalid beds and operating chairs.

#### THE CENSORS' CONFERENCE.

The annual conference of censors was held Tuesday afternoon at the Medical Library. Dr. John Crowell, of Haverhill, in the chair. Dr. John H. McCollom, of Boston, was chosen clerk. Reports from various districts were presented, showing a general maintenance of a high standard for admission. The question of the admission of members of other State medical societies without examination was brought up, and the general weight of opinion was strongly in favor of insisting upon an examination.

#### SECOND SESSION.

The exercises of the second day were begun soon after nine o'clock, when the President, Dr. Gage, called to order the Fellows assembled for the business of the annual meeting.

The records of the last annual meeting were read by the Secretary, Dr. Francis W. Goss, of Roxbury, and the annual reports of the Secretary and of the Treasurer, Dr. Frank W. Draper, of Boston, were presented and accepted. From these it appears, that there was last year in the Treasury, an unexpended balance of \$1,767.37; receipts during the year, \$10,516.21; expenditures, \$8,201.00; leaving a balance of \$2,315.21, and there are invested funds to the amount of \$32,420.17, bearing 3 4-5 per cent interest. Dues to the amount of \$55.00 have been remitted. During the year 95 new members have been admitted; 26 have died; 12 have lost their membership by removal from the State; 4 have been dropped from the roll for non-payment of dues; leaving 1,661 members, a net gain of 55 over last year.

A communication was presented from the finance committee of the coming International Medical Con-

gress, inviting a contribution from the Society to assist in defraying the expenses of the congress. It was voted to instruct the secretary to reply to the committee and state that the Society's charter forbade such use of its funds.

Dr. EDWARD H. BRADFORD, of Boston, on behalf of one of the sections of the Suffolk District Medical Society, moved the appointment of a committee by the chair, to investigate the subject of physical culture in our schools and report at a future meeting. It was so voted, and the following were appointed as such committee: — Dr. Z. B. Adams, of Framingham; Dr. E. H. Bradford, of Boston; and Dr. C. F. Withington, of Roxbury.

The literary exercises were then begun anew, by a paper entitled

#### A CONTRIBUTION TO THE STUDY OF THE ETIOLOGY OF THE SUMMER DIARRHŒA OF INFANTS,

by HENRY C. HAVEN, M.D., of Boston.

This paper was in continuation of the reader's paper of last year, and represented conclusions derived from a series of tables compiled from literal copies of the returns of death throughout the State. From them Dr. Haven argued that urban residence, while not without importance in its relations to diarrhoeal diseases, was not a marked etiological factor. The cause was rather to be sought in alterations in the food ingested.

This was followed by a paper on

#### SEPSIS AND ANTISEPSIS IN SUMMER DIARRHŒA,

by S. ALLEN POTTER, M.D., of Roxbury.

The important cause of summer diarrhœa the writer consider to be fermentative changes in the food. For three fermentative processes a specific micro-organism has been found, and possibly one will be for the others. The reader's conclusions, therefore, were, that micro-organisms bear a causative relation to the processes which contribute to summer diarrhœa; that, therefore, antiseptics are necessary in treatment; that antiseptics is to be found not only in drugs but in the environment of the patient; and that there is room for farther study of the subject.

Dr. HAVEN endorsed the reader's views heartily.

Dr. H. J. MILLARD, of North Adams, believed in preventive treatment, in getting good milk from one cow, and in keeping the cow in good condition.

The next paper was upon

#### TRAINING NURSES,

by ALFRED WORCESTER, M.D., of Waltham.

The reader spoke of the need of skilled nursing by the middle classes, who cannot afford to pay the present high prices that trained nurses command. To meet this need, which the large hospital training-schools are unable to do, physicians must themselves train nurses. Dr. Worcester presented in illustration the training-school at Waltham, where a class of seven was graduated last year, which has now a class of eight, and which continues in successful operation. He believed that in the smaller cities and towns, similar schools could be maintained.

Dr. WALKER CHANNING, of Brookline, took issue with the reader, saying that while such a plan might possibly be feasible in the smaller cities, it was impossible in the country, since the only real success is found where there is abundance of clinical material.

Just as no medical school succeeds well outside of a large city.

The concluding paper of the session was entitled  
THE VALUE OF PUBLIC HEALTH MEASURES TO THE STATE,

by SAMUEL W. ABBOTT, M.D., of Wakefield.

This was a paper replete with statistics in reference to Massachusetts and with arguments and conclusions founded upon them. Among other matters, the reader alluded to the fact, that, while one hundred cities and towns in the State have a system of water-supply, hardly half-a-dozen have a good system of sewerage; and yet, in spite of this, the death-rate has slightly diminished. And it has diminished so much in the preventable diseases as even to suggest the disappearance of some of them in time. The average age of death, too, has increased from twenty-seven in 1851, to thirty-three in 1885. Among the recent valuable laws are the food and drug act, the act in relation to water-supply, and the act creating as an independent organization the State Board of Health.

DR. H. I. BOWDITCH, of Boston, after referring to his deep interest in the State Board of Health, went on to speak of the physical condition of the children of the State. Massachusetts stood to-day in a ridiculous and improper position in regard to physical exercises. Hardly a day passed that some young woman or young man did not come to him who had a mind over-stimulated and was dying of consumption. School-masters are constantly stimulating the minds of these young people and neglecting their bodies. It is arrant nonsense—gross stupidity—to go on in this way. How can you have a sound mind if there is no sound body to keep it in? We ought to have some physical exercises in our schools. The children ought to be exercised physically every morning and afternoon, and the exercises ought to be practical gymnastic training.

DR. EDWARD COWLES, of Somerville, superintendent of the McLean Asylum for the Insane, said that his experience in the Asylum led him to think that there was something wrong in the present school training.

DR. ASA MILLETT, of East Bridgewater, said that one cause of the general apathy in the matter, arose from the neglect of physicians to properly inform the people, who are densely ignorant on sanitary matters, in support of which view he cited cases in his own experience.

The following delegates were then introduced by the President, and responded with brief speeches: Dr. Wallace K. Oakes, Auburn, Me.; Dr. William T. Brown, Jewett City, Conn.; Dr. Norman P. Wood, South Londonderry, Vt.; Dr. Philander A. Harris, Paterson, N. J.; Dr. Daniel Lewis, New York City.

#### THE ANNUAL DISCOURSE.

This carried the exercises up to twelve o'clock, and after a brief intermission, the Fellows were again called to order to listen to the annual address, delivered by DR. GEORGE J. TOWNSEND, of South Natick, upon

THE POSITION OF THE MASSACHUSETTS MEDICAL SOCIETY; ITS RELATIONS TO MEDICAL PROGRESS, TO THE COMMUNITY IN WHICH WE PRACTISE, AND TO ITS FELLOWS,  
which is published in full in this and the preceding number of the JOURNAL.

(To be continued.)

#### AMERICAN CLIMATOLOGICAL ASSOCIATION.<sup>1</sup>

##### FOURTH ANNUAL MEETING.

EVENING SESSION, AT 8 P. M.

CAUSES OF CARDIAC FAILURE IN HIGH ALTITUDES, by DR. FRANK DONALDSON, of Baltimore.

The important fact that there is often great dyspnea and sudden cardiac failure on going to high altitudes, has not been sufficiently emphasized. Many patients are sent for general or special reasons to high altitudes, and are thereby done great injury, especially if they suffer from any form of functional or organic heart disease. From some experiments with the pneumatic cabinet, the author had come to the conclusion that this treatment should not be employed in cases in which there is any valvular disease of the heart, or fatty degeneration of its walls. Before being subjected to treatment in the cabinet, an examination of the heart should always be made. It has been asserted that the cause of the cardiac failure in ascending to high altitudes is want of oxygen. The speaker had performed certain experiments with reference to this point. At altitudes within ten thousand feet, there is sufficient oxygen to supply the hemoglobin. In ascending to high altitudes, the pressure of the air within and without the lungs is the same, but on the heart the action is different. The pressure is removed from the outer surface of the heart, while the internal blood-pressure remains the same. There consequently must be dilatation of the heart-walls. This, in the author's opinion, was the cause of the heart-failure under these circumstances.

##### DISCUSSION.

DR. B. F. WESTBROOK, of Brooklyn. I have no doubt that the explanation of the author with reference to the effect of high altitudes on the heart is correct, but in the pneumatic cabinet the conditions are different. Where the patient inhales compressed air, or sits in a rarefied atmosphere and inhales air at the ordinary pressure, there is an absolute or relative increase of pressure within the thorax. The heart is, therefore, submitted to a relatively increased pressure. As a matter of practical experience, I have found that patients with mitral stenosis or mitral regurgitation, with pulmonary congestion, can be put in the cabinet with safety. I should scarcely claim that the same rule could be applied to cases of aortic disease. I should hesitate very much before putting a patient with aortic regurgitation into the pneumatic cabinet. In mitral disease, however, the tendency is to assist, rather than exhaust the diseased heart.

DR. H. F. WILLIAMS, of Brooklyn. Certain New York observers have claimed that in weak heart, particularly the "tobacco-heart," they have obtained with the pneumatic cabinet an effect similar to that of digitalis, due, probably, to a stimulation of the circulation through the coronary arteries.

DR. S. S. COHEN, of Philadelphia. The heart is habituated to a certain pressure of the atmosphere (754 mm. of mercury). When the individual goes into a rarer atmosphere, there is a disturbance of the relationship between external and internal pressure, and this disturbance will necessarily bring upon the patient disease. The inhalation of compressed air in cases of dilated heart has been recommended by Waldenburg and others. I have recently employed

<sup>1</sup> Continued from page 562.

this measure, with beneficial results, in alleviating the dyspnoea and defective circulation due to a dilated heart.

DR. JAMES T. WHITTAKER, of Cincinnati, O. The condition met with in a rarefied atmosphere cannot be compared with that met with in the pneumatic cabinet. It does not seem possible to exert any mechanical pressure upon the heart in the cabinet. The conditions which have been observed admit of easier explanation by a study of the effects on the surface vessels. When the pressure is removed from the superficial vessels, the dilated heart propels the blood easier than before. This is one of the most efficacious means of treating irregular heart. I have used the cabinet for two years, and have seen no ill effects from its use, although I should not subject a patient with advanced cardiac disease to this plan of treatment.

**SOME HOSPITAL CASES OF PHTHISIS: MARKED IMPROVEMENT UNDER GENERAL TREATMENT, WITH SPECIAL REFERENCE TO ALIMENTATION,**

by DR. F. C. SHATTUCK, of Boston.

The cases reported had been treated in the Good Samaritan Hospital of Boston, which is devoted to the care of chronic disease. Many of the patients had been exposed to unfavorable hygienic surroundings. The treatment employed was devoted largely to improvement of the general condition. Search had been made for a specific treatment. If the disease is of a parasitic nature, it is natural to suppose that such a treatment would be of avail. At present, no such method of treatment is known. There are few individuals to whose lungs, at one time or another, the bacillus does not gain access. The fact that certain individuals are affected, while others escape, forces us to believe that there is a predisposition to the disease. The treatment employed by the author had consisted in relieving symptoms, improving the digestion, and the administration of as much food as the patient could take in the natural way. Artificial feeding had not been resorted to, but the patient was fed six or seven times a day. From two to ten raw eggs, with milk, were given daily to each patient. Alcoholic stimulants were not administered to these patients as a routine treatment, but were used only temporarily for special purposes. He had, for several years, been systematically cutting down the quantity of alcohol used in chronic cases, and had seen no reason to regret it. His experience had been that alcohol was not used with sufficient discrimination in chronic cases of diseases. Beef, milk, eggs, and other nourishing articles are more expensive than alcohol, but if they can be consumed in sufficient quantity, they are more useful. In 1883, the amount expended per patient for alcoholic liquors had been \$2.70, while in 1886, it had been only thirty-four cents. The patients received no injury, even if they were not benefited by this reduction. Eight cases of well-marked phthisis were reported, in which a decided gain in weight and general improvement resulted from the employment of the plan of treatment above described. About sixty cases had been under treatment.

**DISCUSSION.**

DR. E. T. BRUEN, of Philadelphia. Of the therapeutic measures under the control of the profession, diet, climate, and suitable hygiene are of principal importance. It is possible, by climatic and dietetic

treatment, to so change the nature of the tissues, that they shall not be suitable culture media for the growth of the bacillus of tuberculosis. I wish, however, to refer more particularly to the use of the Bergeon method by the injection of sulphuretted hydrogen. To antagonize the specific cause of the disease, this method has been a failure, so far as my experience goes. Since February last, I have had under treatment sixty-one cases by this method. Systematic examinations of the sputa have been made by Dr. E. O. Shakespeare. There has been no apparent reduction in the number, or change in the character of the bacillus. This method should be classed among the methods at our disposal for the treatment of this disease. The good effects in my hands have been reduction of temperature, reduction of expectoration, very often a complete suppression of bronchial catarrh, and relief of cough. This leads to improved digestion, and enables the dietetic treatment to be carried out with great thoroughness. Forty-four of these cases showed improvement to a certain extent, the average gain in flesh being about five pounds. In one-half of the cases the temperature has been brought to the normal, while in the remainder, although the temperature has not been brought to normal, it has been reduced two or three degrees. In fifteen cases the results have been negative, but in no case did any harm follow the use of this plan of treatment. The improvement has been most marked where there is considerable catarrhal element. Those cases in which there has been more or less thickening of the lung, with the general symptoms well marked, wasting, loss of flesh and weight, without much rise of temperature, I have found were not specially benefited by the injection of gas. I have had the opportunity of making a post-mortem in one case which had been subjected to this treatment. Although the cavities in the lungs were unusually clean, I did not observe any evidence of cicatrization. With reference to the strength of the solution, I have not found strong solutions at all satisfactory. The best results have been obtained from a solution of five grains of sulphide of sodium, with five grains of chloride of sodium in one-and-a-half pints of water. I have never found it desirable to administer more than a gallon-and-a-half of gas at one time. I insisted that the injection be made slowly, and that one-half to three-quarters-of-an-hour should be occupied. I have not derived as much satisfaction in the treatment of the various forms of phthisis to which I have referred from any method as I have from the injection of sulphuretted hydrogen. I have always tested the breath for the presence of sulphuretted hydrogen. I have had negative results in, at least, eight out of every ten cases.

DR. S. S. COHEN, of Philadelphia. The experience of Dr. J. Solis Cohen and myself differs in some respects from that of Dr. Bruen. We have obtained the most decided benefit from strongly impregnated waters. The best results were obtained in those cases in which the patient had a decided taste of sulphuretted hydrogen, which continued for two or three hours after injection. The best effect has been obtained in those cases in which suppuration is about beginning. Bergeon states that the treatment is directed especially to the suppurative process. In employing this measure, great attention must be paid to detail. In about fifty per cent. of the cases, the condition has been greatly ameliorated. In another twenty-five per

cent. there was slighter amelioration, while in the remaining twenty-five per cent. there was more or less benefit to certain symptoms. I have seen no case in which no results were obtained.

DR. JAMES T. WHITTAKER, of Cincinnati. I have for a month used sulphuretted hydrogen by inhalation, having previously employed it for a month by injection. I began the use of inhalation carefully, and finding it well borne, I have pursued the method more boldly. I now put the patients in the cabinet, and allow them to have all the gas they will take. It has produced no unpleasant results in any case. The effects obtained have been about the same as those resulting from injection. In about one-third of the cases there were no results. I have searched the literature for records of bad results following the use of sulphuretted hydrogen, and have found only two in which a fatal result followed. It has been asserted that the good effect is due to the carbonic acid, but I am entirely incredulous of the effect of this agent.

DR. ROLAND G. CURTIN, of Philadelphia. It has been recommended by Dr. H. C. Wood that the sulphuretted hydrogen be taken by the stomach, using a saturated solution, through which carbonic acid has been passed. I have tried this in four or five cases, and have had the same effects as from injection.

DR. J. H. MUSSER, of Philadelphia. I have used the gaseous injections to a certain extent, but my results have not been as marked as some which have been reported. My best results have been in two cases: one was a case of incipient phthisis, in which the patient gained thirteen-and-a-half pounds in four weeks. The second case has gained eight pounds in four weeks, and has much improved in general condition. I attribute my want of good results, in part, to the want of enthusiasm on the part of those whose duty it is to carry out the details of the treatment.

DR. F. C. SHATTUCK, of Boston. I have used the sulphuretted-hydrogen gas, and in several patients it produced collapse in varying degrees, with weak pulse, nausea, vomiting, and headache. In several other cases, although the treatment was well tolerated, it produced no good effect. In one case of asthma, with chronic bronchitis and emphysema, thirty-four injections of the gas were given. While the treatment did not disturb the patient, it did no good. With the use of the gas was combined the administration of iodide of potassium and other remedies, and the patient recovered in about the same time as on a previous occasion, when the latter remedies were given and no gas used.

(To be continued.)

#### ASSOCIATION OF AMERICAN PHYSICIANS. SECOND ANNUAL MEETING.

THE second annual meeting of the Association was held in the Army Medical Museum Building, Washington, June 2 and 3, 1887.

#### THURSDAY, FIRST DAY. — MORNING SESSION.

The meeting was called to order, at ten o'clock, by the President, DR. S. WEIR MITCHELL, of Philadelphia, who delivered a brief address, in which he referred to the purposes of the Association as being purely scientific, and difficult ethical questions and medical politics as having no place among the works of this

Society. He referred to the great desirability of making the meeting of the Congress of American Physicians and Surgeons, to be called in the autumn of 1888, a success. In conclusion, he reported the death of three members: Dr. Thomas F. Rochester, of Buffalo; Dr. Thomas A. McBride, of New York; and Dr. E. D. Hudson, Jr., of New York.

After the transaction of routine business, the first paper, entitled,

#### CIRRHOSIS OF THE LIVER IN CHILDREN,

was read by DR. R. PALMER HOWARD, of Montreal.

He reported two cases in which cirrhosis of the liver was present in children, brother and sister. He exhibited sections of the organ.

#### DISCUSSION.

DR. WM. A. WELCH. I recall one case, in which I made autopsy, in a case of cirrhosis in a child, twelve years of age. He came from the coast of Africa, and suffered with malaria. Both the liver and spleen were deeply pigmented. The clinical features of the case could not be obtained. Most of the cases of cirrhosis of liver of malarial origin have been reported from the coast of Africa. Very little has been brought forward in this country with regard to the malarial origin of cirrhosis.

DR. F. FORSHMEIER, of Cincinnati. I have seen two cases that may possibly be called cirrhosis. One was that of a child of eight years. At the post-mortem, the characteristic hob-nail liver was found. In this case, I considered the cirrhosis due to syphilis. The second case is now under observation in the Children's Hospital of Cincinnati, the patient being in the last stage of cirrhosis. In this case there is a history of syphilis, and the child has hereditary syphilis of the nervous system. To my mind, it is clear that syphilis is the most common cause of cirrhosis of the liver in children.

DR. WILLIAM PEPPER, of Philadelphia. I have the complete records of a case in which cirrhosis of the liver followed measles in a child, eight years of age. There was no syphilitic history. During the attack of measles there were symptoms of hepatic disorder, as shown by occasional attacks of catarrhal jaundice. Subsequently, the symptoms of developing cirrhosis made their appearance, and death in a comatose condition finally occurred. The whole duration of the case could not have been less than a year. At the autopsy, a typical hob-nail liver was found. The liver had been much enlarged, but it had gradually contracted, so that at the time of death it was of about the normal size.

#### OBSTRUCTIVE SAFETY-VALVE ACTION IN THE HEART AND DIRECT FUNCTIONAL MURMURS,<sup>1</sup>

by DR. JOHN GUITERAS, of Charleston.

In a previous paper on malignant endocarditis, the author had dwelt upon the significance of mitral, direct pre-systolic murmurs, which were proven by the autopsy to be unconnected with any lesion of the mitral orifice. The lesions were those of intense aortic regurgitation. He had attributed the murmurs to the recoil of the blood upon the mitral leaflets, holding them tense against the stream of blood coming from the auricle. In the opinion of the late Dr. Flint, direct functional mitral murmurs were limited to a

<sup>1</sup> To be published in a future number of the Journal.

small number of cases of aortic regurgitation, but the author thought that functional mitral murmurs were not so rare. Obstructive functional murmurs are common in aortic regurgitation.

Pulmonary systolic murmurs are more frequent than any other form of cardiac murmurs. In examining one hundred consecutive cases, he had found, in sixty-two, systolic pulmonary artery murmurs. In these, the murmurs were present during tranquil breathing, or during respiration, in such a way as to produce changes in the pulmonary circulation. If account is taken of the bruits heard in this region, the proportion becomes greater. The clearness with which these murmurs are heard depends upon the proximity of the artery, the thinness of the chest-walls, the nature of the surroundings, and finally, the proximity of the main trunk to the capillary distribution. Systolic pulmonary murmurs can be developed in the majority of healthy individuals, if we exclude those with thick chest-walls, and those who are not intelligent enough to modify their breathing as directed. The author held that such a murmur was a dynamic, obstructive, valvular murmur, and is produced by the effect of changes of blood-pressure upon the semi-lunar valves. A certain degree of pressure in the artery must tend to prevent the opening of the valve. This causes a slanting position of the valves and a narrowing of the orifice, with the production of a sonorous whirl. The fact that such murmurs are not more frequently developed at the aortic orifice is due to the greater power of the ventricle, and the wider distribution of the systemic circulation. There are, however, cases in which increased arterial tension is expressed not only by accentuation of the aortic second sound, but by an aortic systolic murmur. He had heard it in atheroma and in Bright's disease, where there was no marked anemia. Pulmonary-artery murmurs, as heard in ordinary breathing, are confined to the expiratory act, and are loudest at the beginning of the act. The murmur is sometimes only heard with the first beat that occurs with expiration. In order to further develop this murmur, it is only necessary to arrest respiration. It is better to stop breathing during expiration, especially at the end of normal expiration. A full expiration makes the murmur louder. At the end of inspiration it is more difficult to develop the murmur, for several reasons: (1) because it requires entire arrest of respiration to produce engorgement of the main trunk; (2) because prolonged inspiratory effort is accompanied by a continued hum of the intercostal muscles; (3) because the expansion of the lung interferes with the transmission of any murmur that may be present. A slight murmur is frequently heard in inspiration if the arrest of breathing is pushed far enough. The speaker asked: Are we not justified in assuming that there is a safety-valve action in this attitude of the pulmonary valve, which, together with the leakage at the tricuspid orifice, tends to prevent engorgement of the lungs by retardation of the flow of blood in the systemic veins, so that, continued for a time, it does no harm? In reference to the murmurs of anemia, the author thought that they were due to some disturbance of the valvular apparatus. In this condition, there is a marked reduction in the quantity of blood. The valves require a certain amount of expansion of the vessels, in order to allow them to apply themselves to the walls. Venous hums and basic murmurs, he thought to be of valvular origin.

#### DISCUSSION.

DR. A. L. LOOMIS, of New York. Many different explanations of murmur within the heart cavities have been given. We should recognize that they are due to many different causes. Many are obstructive in character while others are due to the impinging of currents of blood upon each other in the heart. They are also due to the force with which the blood current is carried from the heart into the vessels. They are also due to or greatly intensified by the condition of the blood. It seems to me that they may also be due to irregular action of the heart produced by nervous condition. The obstructive mitral murmurs referred to are, I think, of frequent occurrence in connection with aortic disease where there is dilatation and feebleness of heart power, but on autopsy I have always found such changes in the mitral valves as seemed to me to account satisfactorily for the murmur heard. I have heard the murmurs so readily produced during respiration, but when these murmurs have been persistent I have always found conditions of anemia and failure of the right heart. It seems to me that the explanation is either anemia or failure of heart power. I think that we shall, as we study the cases more, find that they are due not so much to changes in the valvular orifices as to changes in the heart cavity, and in the heart walls. Murmurs have come to be of very little pathological significance to me unless there are other changes associated with them. The worst cases of heart disease that I have met with, have had the simplest and least distinct heart murmurs.

DR. E. T. BRUEN, of Philadelphia. In a case of anemia which I have recently studied, the blood corpuscles were reduced from the normal to 1,800,000, with a great reduction in the hemoglobin. There was also great relaxation of the vascular system, so much so that as the arm hung out of the bed, there was a venous pulse at the back of the wrist. This was attributed by Dr. Osler and myself to relaxation of the capillary vessels to such an extent as to permit the systolic impulse of the left ventricle to force the blood through the capillaries into the veins. There was no venous pulse in the neck. In this case there were murmurs at each of the valves of the heart. As the anemia improved and the crisis of the blood was restored, the venous pulse disappeared, and the murmurs gradually lessened and the man has now no murmur whatever. This case is corroborative of the view of the author that in anemia the murmurs are due to some functional disturbance of the valve.

DR. F. P. KINNICUTT, of New York. It has been claimed by certain observers that pulmonary systolic murmurs are transmitted from the mitral valve into the auricular appendage. The condition required that this may occur is said to be dilatation of the appendage causing it to approach the chest wall. In some anatomical examinations made a few years ago, I found that in the normal condition the auricular appendage was concealed beneath the pulmonary artery and when fully dilated, its tip only could be seen beyond the edge of the artery. It was even then one-and-a-half inches from the internal surface of the chest.

DR. F. C. SHATTUCK, of Boston. When auscultation was first introduced, all cardiac murmurs were considered of bad omen. It was then discovered that many systolic murmurs were practically of no importance. We are now finding out that all diastolic mur-

murs are not of evil import, and that they may be transitory and functional. A murmur by itself is next to nothing, there must be something beside the murmur to make it of much importance. The author has stated that in anemia there is a reduction in the quantity of the blood. I would ask, is not the reduction more in the quality,—a corpuscular reduction and a reduction in the capacity of the corpuscles for carrying hæmoglobin?

DR. SAMUEL C. CHEW, of Baltimore. With reference to the diagnosis between aortic, regurgitant and mitral direct murmurs, I would say that I think that the diagnosis can usually be made by attention to the following points. An aortic diastolic murmur, although it may be intense at the apex, becomes manifestly louder as we reach the right side of the sternum in the second intercostal space. It will then occupy the whole diastole. If the murmur is mitral in origin, it generally will be presystolic, and will be also heard in the scapular region. The aortic murmur is not apt to be heard in the latter situation.

DR. BEVERLY ROBINSON, of New York. I have occasionally found in acute strain of the heart, not necessarily brought about by great muscular exertion, murmurs which unquestionably had nothing to do with organic changes in the heart, and cannot be explained as due to any special modification in the blood. The murmurs seemed to be due to more or less acute dilatation or obstruction of the mitral orifice. These murmurs I think, have considerable prognostic importance, for if they do not receive careful attention and proper treatment, they may continue for a considerable length of time, and then become of more or less grave import.

DR. ISRAEL T. DANA, of Portland. I have had under my observation two sisters, one forty years of age and the other thirty-three. The mother died of organic heart disease. Both of these sisters have had a mitral regurgitant murmur. In the elder sister the murmur after remaining for five or six years, disappeared. It remained absent for one or two years and then returned and has continued for the past two or three years. In the second case, the murmur after having been present for five or six years, disappeared and has since remained absent. I would ask if it is possible that a murmur connected with organic heart disease should disappear with improvement of the health and reappear when the health again fails?

#### PNEUMATIC DIFFERENTIATION,

by DR. HOSMER A. JOHNSON, of Chicago.

In the absence of the author the paper was read by the secretary. The author had compared the results obtained by the cabinet with those obtained by the Waldenburg apparatus, and he held that the former accomplished no more than the latter. The pneumatic cabinet he considered cumbersome and expensive, with nothing to especially commend it in the treatment of pulmonary diseases.

The last paper of the morning session was entitled

#### METHODS OF LITERARY RESEARCH,<sup>2</sup>

by DR. JOHN S. BILLINGS, U. S. A.

The author referred to the best way of using libraries with especial reference to medical literary work. He also spoke of the great importance of carefully prepared catalogues of books.

<sup>2</sup> To be published in a future number of the Journal.

#### AFTERNOON SESSION.

##### THE ANTIPYRETIC TREATMENT OF FEVER,

by H. C. WOOD, M.D., of Philadelphia.

In order to make the matter as brief as was possible, he had prepared certain propositions which he would read, and then give what he thought to be the proof of their correctness.

*First*, "Fever is a disturbance of calorification in which through the influence of the nervous system heat-dissipation and heat-production are both affected. If there be a fever which is produced by the direct action of a poison independently of the nervous system we have at present no proof of its existence." If an animal's temperature rises, there must be a certain number of heat-units used in producing that rise. If the temperature falls there must be a corresponding lessened production of heat. In his experiments the agent used to produce the fever has been the pyrogenic principle found in ordinary commercial pepsin. After the substance has been introduced the animal is put into a calorimetre. The animals used in the experiments have been dogs. In the normal animal heat-production and heat-dissipation are correlated functions. When the poison is injected it is found that heat-dissipation increases at the time that heat-production is diminishing, so that the fall of temperature was in part the result of heat-dissipation, and in part the result of diminished heat-production. It is impossible that there should be this wide disturbance of these two functions simultaneously, unless the poison which produces the fever acted upon some one central organ, and that must be the nervous system. McCallister, of London, while believing that fever is often produced through the nervous system, thinks that at times it may be produced by wide-spread tissue change caused directly by the poison, his reasoning being that in the advanced stage of fever the temperature is higher than at the beginning. He says that the time when the poison is at its maximum, does not correspond to the time when the fever is at its maximum. The objections to this argument is that we do not know that the poison of the disease is the direct cause of the fever. The poison which causes the disease in scarlet fever, etc., is probably not the poison which causes the fever. The latter is probably generated in the system.

*Second*, "Heat-production is regulated by a nervous apparatus, our knowledge of which is still imperfect. There is certainly an inhibitory centre which depresses or controls the production of heat. It probably does this by acting upon the trophic cells of the gray matter of the spinal cord. It is possible, also, that there is a centre which when excited, increases tissue change, but its existence has not yet been proven." The speaker then gave a *résumé* of the experiments which he had performed, which in his opinion, proved the truth of the above proposition.

*Third*, "Heat-dissipation is regulated through the vaso-motor system so that vaso-motor paralysis is followed by an enormous loss of animal heat, and under unfavorable circumstances, by death from cold." If section of the cord is made in such a way as to get vaso-motor paralysis without destruction of the respiratory centres, the heat-dissipation rises enormously. If the animal is kept in a temperature of fifty or sixty degrees, it dies in a few hours of progressive loss of heat. If kept in a warm chamber it lives for days.

The cause of the rapid heat-dissipation is the opening of the bloodvessels of the surface of the body.

When these remarks are applied to a study of antipyretics, it is seen that drugs may lower bodily temperature, in health or in fever, by increasing heat-dissipation. In this way act all agencies which cause vaso-motor paralysis. Antipyretics acting in this way may be called false antipyretics. Then it is conceivable that there may be drugs which act on heat-production through the inhibitory nerve apparatus, of which mention has been made. Such drugs may for convenience be called true antipyretics. Aconite, veratrum viride, and drugs of that class, belong to the false antipyretics. Whether or not there are any true antipyretics has until recently been a question which we have been unable to answer. With regard to antipyrine certain experiments made in the University of Pennsylvania, seem to give some positive results. Care must be exercised in these experiments, not to confound a normal defervescence with the action of the drug administered. In the dog, the use of antipyrine diminishes both heat-production and heat-dissipation; the former being diminished more than the latter. It is probable that heat-production is primarily affected. The question arises, whether this result is due to an effect on the circulation? He had found that antipyrine had no effect upon the circulation. The blood-pressure was uninfluenced by its administration. He therefore concluded that the action of antipyrine upon the bodily heat was entirely independent of any action upon the circulation, and the probabilities are of course that it acts through the nervous system. Beyond this our present knowledge does not extend.

#### THE TREATMENT OF TYPHOID FEVER BY ANTIPYRINE AND THALLIN.<sup>2</sup>

by FRANCIS MINOT, M.D., of Boston.

The following conclusions were reached. (1) Both antipyrine and thallin have a remarkable power of reducing the temperature in typhoid fever. (2) In no case was the use of these refrigerants apparently followed by any unfavorable effect upon the course of the disease. (3) The general condition of the patient was more comfortable after taking antipyrine and thallin, which were often followed by sleep. (4) The refrigerant medication by antipyrine and thallin appears to have no specific or decided effect upon the course or issue of typhoid fever. It often contributes much to the patient's comfort, perhaps indirectly promotes his safety. (5) The effect of antipyrine and thallin in promptly lowering the temperature shows that the danger in typhoid fever does not consist in high temperature alone, and that the latter is rather an index of the violence of the abnormal condition which we call fever, though perhaps adding somewhat to the danger. (6) By the internal use of antipyrine and thallin all the effects which are claimed for the treatment of typhoid fever by the cold bath are readily obtained without the trouble and inconvenience of the latter method, and without exposing the patient to the dangers of exhaustion and shock consequent on the fatigue of removal from bed. (7) These remedies may be given without danger to the youngest patients, in suitable doses, and indeed their beneficial effects are more decided and the unfavorable consequences are less observable than with adults.

<sup>2</sup> To be published in a future number of the Journal.

#### DISCUSSION.

DR. I. E. ATKINSON, of Baltimore. So far as the temperature-reducing power of these agents is concerned, there can be no question; but, as has been said, we are coming more and more to realize that elevation of temperature is far from being all there is in pyrexia. As regards the relative merits of thallin, antipyrine and antifebrin, I think that the tendency to chilling after the use of thallin, is decidedly greater than after the use of antipyrine, while the latter is more apt to produce nausea and vomiting. I am disposed to disagree with the statement that the use of these drugs can take the place of the external application of cold water. My experience with the latter measure has been limited. It has recently been reported that one observer abroad has treated two hundred cases in private practice by the use of baths, with a mortality of nothing. In army hospitals he has had a mortality of five per cent., and in ordinary hospital practice a mortality of less than eight per cent. Although with antipyretics we can reduce the temperature at pleasure, yet the duration of the case is not lessened, and in some cases it has been thought to have been prolonged.

DR. H. C. WOOD, of Philadelphia. We must not look upon the use of cold water as acting merely by the abstraction of heat. I am convinced that the action is more than this. It probably exerts some influence through the superficial nerves.

DR. GEORGE L. PEARBODY, of New York. I have found that a certain proportion of cases which do not bear the cold bath will bear the use of antipyretic drugs, while on the other hand, the bath may be used in a certain number of cases in which antipyretics cannot be applied. From clinical experience I have been convinced of the truth of the statement of Dr. Wood, that the cold bath accomplishes more than the simple reduction of temperature. Its soothing effect upon the nervous system is greater than that accomplished by the reduction of temperature by antipyretic drugs. I believe that in many instances the course of the disease is favorably modified by the use of the cold bath.

Another important matter is that since the introduction of these methods of antipyresis, the number of relapses seem to be greater and more fatal.

I understood Dr. Wood to say that antipyrine acted solely by diminishing heat-production and that it did not increase heat-dissipation. I must differ from him on that point. It seems to me that the increase of heat-irradiation from the surface is very great, not only where it produces sweating, but also where it does not.

DR. W. W. WELCH, of Baltimore. I should like much to hear discussed the question how far rise in temperature is an important element in fever and an element which calls for interference on the part of the physician. There is comparatively little evidence that the grave symptoms of fever are referable to the elevation of temperature. There is no doubt that temperatures of 110° to 113° produce serious symptoms, but whether or not ordinary temperatures of 105° to 107°, exert any serious action on the body, is a question which is certainly unsettled. It has been shown that rabbits can be kept in a box with a continuous rectal temperature of 107° for at least two weeks, provided the precaution is taken to keep the box well ventilated and the animals supplied with

moist food. Patients may have a perfectly clear brain and no grave symptoms, with a temperature of  $106^{\circ}$  or  $107^{\circ}$ . On the other hand, there are severe and fatal cases of typhoid fever in which the temperature has never registered a great height. While in most cases there is a certain proportion between the height of the temperature and the severity of the disease, yet there are certain cases where this proportion does not exist.

DR. WILLIAM PEPPER, of Philadelphia. From my experience, I have been disposed to think that antipyrine and antifebrin were superior to thallin; between the two former I have not noticed any marked difference. I have used both largely in a variety of cases and have not seen any of the dangerous symptoms which have been mentioned by some writers. The action of these drugs seems to be purely through the nervous system. I have seen no effect upon the circulation, upon the respiration, or upon the secretions, save that of the skin. Some of my observations have been of interest with reference to the relative value of the external use of cold water and the internal use of antipyretics. In the sudden acute pneumonia of children with a temperature of  $106^{\circ}$  or  $107^{\circ}$ , with initial convulsions, where the prompt and repeated use of cold baths has been without gratifying results, full doses of either of these antipyretics have produced a remarkably successful effect. In a recent case in a child with double croupous pneumonia involving two thirds of the left lung and one-third of the right lung, with a temperature in the rectum of  $107^{\circ}$ , and with repeated convulsions, cold baths failed to relieve the symptoms, although repeated at intervals of three hours. Antipyrine in repeated doses controlled the pyrexia at the beginning and on several occasions during the course of the disease, and after a severe struggle the child recovered. As to the ability of these agents to replace cold baths under all circumstances the evidence is not adequate. In the sudden hyperpyrexia occurring in the course of rheumatism, I am not prepared to accept the view that these drugs are capable of replacing the cold bath. In these cases we have direct evidence that the high temperature is the direct cause of the symptoms, at least of the severe nervous symptoms. I am not one of those who consider high temperature in itself a dangerous symptom. There is no proof that high temperature, provided the high temperature has not induced secondary changes, should be regarded otherwise than as one symptom of the disease. I have had many patients with typhoid fever with a temperature of from  $103^{\circ}$  to  $105^{\circ}$ , who have done perfectly well without any measures directed to the reduction of the fever. We, however, meet with cases in which these temperatures are attended with certain symptoms for which there is apparently no other cause. In such cases we must consider that the hyperpyrexia calls for treatment. I have noticed the effect to which attention has been called, that is, the deep and tranquil sleep which follows the administration of these antipyretics.

DR. GEORGE B. SHATTUCK, of Boston. I have used both antipyrine and antifebrin largely, the former for several years, and it seems to me that antifebrin offers all the advantages of antipyrine without its disadvantages. It has none of the disadvantages which belong to thallin. Three or four grains of antifebrin accomplishes the same results as are produced by a larger dose of the other drugs. The disagreeable

symptoms which some writers have referred to as following antipyrine, are probably due to the fact that they follow the original recommendation and give two grammes of the drug. The same benefit can often be obtained from one gramme, and often from seven grains. With reference to the point suggested by Dr. Welch, I would say that, whether pyrexia is or is not a dangerous feature of the disease, we find clinically, that where a patient has high fever, is irritable, impatient and uncomfortable, the administration of one of these antipyretics or the external use of cold water, produces a tranquil and refreshing sleep, and the patient awakes in a condition much better fitted to continue the struggle with the disease.

DR. J. C. WILSON, of Philadelphia. I am led, from my experience, to agree with other speakers that antifebrin has many advantages over thallin, particularly in its cheapness and in the smallness of the dose. A recent observation which I have made is interesting, as bearing on the question of heat-dissipation. I have lately been treating a case of typhoid fever, in which, from time to time, antifebrin in five-grain doses was given. These were repeated whenever the temperature reached  $104^{\circ}$ . This caused copious sweating, with the usual reduction of temperature, amounting to three-and-a-half or four degrees. On the last occasion, one-ninety-sixth of a grain of sulphate of atropia was given with the antifebrin. No sweating occurred, and the temperature was reduced only one-and-one-half degrees.

DR. JAMES T. WHITTAKER, of Cincinnati. I would differ from the gentlemen who seem to accept the view that fever is a neurosis. We have, I think, no proof that the nerve-centres are distinctly irritated, and we have no proof that the agents which reduce fever act directly on the nervous centres. Is it not more probable that the antipyretic action is really an antimicrobial action? We have some observations which go to show that the disease is caused by bacteria, or, if not directly by bacteria, by some of their products, the ptomaines. Would it not be more rational to study the habits of these bacteria, and address ourselves rather to the removal of the cause than to the counteracting of the effects?

DR. H. M. LYMAN, of Chicago. With regard to antifebrin and antipyrine, my experience has been that of previous speakers, and my preference for the former drug is growing. I am disposed to regard their great value as proceeding not so much from their power to reduce temperature, as from their general effects, especially upon the nervous centres. I regard them as valuable adjuvants in the treatment of disease, largely from their hypnotic and tranquilizing effect upon the nervous system, to which allusion has already been made. I have observed that in many instances where, in abrupt febrile affections, relief has not been secured from antifebrin and antipyrine, this failure is frequently due to the presence of the condition we call rheumatic, and there salicylic acid gives the relief that we fail to get with antipyretics.

DR. JOHN GUIERAS, of Charleston. I have had some experience with these drugs in the treatment of the continued fevers of warm climates, but here the results have been rather negative, and have showed the advantage of stopping their use after they have been continued for a certain length of time. I have been called in consultation where the drug has been continued for ten or fifteen days, each time that it was

given producing a certain reduction of the temperature, but having no permanent benefit, and the patients have begun to improve as soon as the drug was stopped. It has seemed that, when given continuously in this way, they have an effect on the vaso-motor system. The pulse is weak and dicrotic, and I have considered it advisable to give digitalis. The effect of cold-water baths in these continued fevers of the South has seemed to me more beneficial. If continued for two or three days, they often favorably modify the course of the disease.

DR. GEORGE L. PEABODY, of New York. With reference to the point suggested by Dr. Whittaker, there is no question in my mind that a considerable proportion of cases of typhoid fever can be aborted by antiseptic treatment of the intestinal ulcers with naphthaline or resorcine. For the past two years, I have treated all cases coming under observation during the first ten days of the disease with a calomel purge (ten grains), followed by naphthaline in such doses that, at least, seventy or eighty grains are taken during the twenty-four hours. Under this treatment, I have without doubt succeeded in aborting many cases in which the symptoms were quite pronounced. I have not succeeded in cases coming under observation at the end of the second week.

DR. H. C. WOOD, of Philadelphia. In regard to the dissipation of heat by sweating, I would state that in the dog on which the experiments were made there are but few sweat glands. There are a few in the paws and about the mouth so that there could be no heat-dissipation from this cause. Sweating in man does undoubtedly cause a dissipation of heat. With reference to the possible influence of antipyrine on fever through some action on the bacteria causing the fever, I would state that in the experiments to which I have referred no microbes were concerned in the production of the fever which was induced by the pyrogenic principle of pepsin.

DR. JAMES TYSON, of Philadelphia. In a recent case of rheumatism, the temperature suddenly went up to 105° with alarming brain symptoms. Antifebrin in five-grain doses failed to produce any effect. The patient was then put into a cold bath and the temperature of the water gradually reduced to 72°. The discomfort experienced by the patient then prompted his removal from the bath. The thermometer in the rectum showed a reduction of only one-half of a degree, but within the course of half an hour the temperature fell three degrees. I scarcely think that this was a natural defervescence but must attribute it to the effect of the bath. The fall in temperature was followed by a disappearance of all the symptoms, and the recovery of the patient. While I have never seen any serious results from the use of thallin and antipyrine, yet there have been symptoms which caused much alarm to the attendants. I have not seen such symptoms follow the use of antifebrin.

DR. R. PALMER HOWARD, of Montreal. I want to emphasize the fact that internal antipyretics and the cold bath are not equivalents, they are substitutes, and important auxiliaries to the physician. These measures relieve special symptoms but whether or not they shorten the duration of the disease is a question not yet settled. Another important point is with reference to relapse in typhoid fever. This is a subject which requires investigation. I think that every relapse, so-called, is due to the absorption of fresh

poison. It is really a fresh attack. It is really an initial attack. It runs a severe course and often proves fatal.

(To be continued.)

## THE AMERICAN LARYNGOLOGICAL ASSOCIATION.<sup>1</sup>

### NINTH ANNUAL CONGRESS.

FRIDAY, SECOND DAY. — MORNING SESSION.

FURTHER RESEARCHES UPON THE FUNCTION OF THE RECURRENT LARYNGEAL NERVE, BEING A SERIES OF EXPERIMENTS FROM THE BIOLOGICAL LABORATORY OF THE JOHNS HOPKINS UNIVERSITY,

by DR. FRANK DONALDSON, JR., of Baltimore.

At a previous meeting, he had read a paper criticising certain conclusions advanced by Dr. F. H. Hooper, of Boston. The conclusions which Dr. Donaldson reached were: That the constrictors do not cease to act under deep narcosis or suspension of consciousness from any cause; that we do not always obtain abduction on irritation when consciousness is suspended; that the abduction was not reflex, and was not dependent on unconsciousness; that it is with weak stimuli that abduction takes place, and the movement passed into adduction as the stimulus was increased. These results invariably followed, whether the animal was slightly or deeply narcotized, or when the medulla was destroyed, or when local death had taken place. That, after strong or continued stimuli, the abductor muscles became worn out, and did not respond to stimuli.

These conclusions had been strongly criticised, and the present series of experiments were performed to test the correctness of the above views. He had shown that abduction of the vocal bands can be obtained without ether, and that it is a physiological fact that opening or closing of the larynx depends upon the strength of the stimulus. With weak stimuli abduction was produced, while with strong stimuli adduction was caused.

THE ANATOMY AND PHYSIOLOGY OF THE RECURRENT LARYNGEAL NERVE: FROM THE PHYSIOLOGICAL LABORATORY OF THE HARVARD MEDICAL SCHOOL,

by DR. FRANKLIN H. HOOPER, of Boston.

The anatomy of this nerve is now complete and exact, but up to a very recent date, much confusion existed on this subject. To find out why these nerves are recurrent, it is necessary to begin with the embryo. The recurrence is due to certain changes in the bronchial arches, and the descent of the heart into the thorax. At one time in the period of development these laryngeal nerves are straight, but, as the heart descends, they are brought down. The proof of this is found in the abnormal condition of the nerve in cases of irregularity of the great vessels which branch from the aorta. These nerves (at least, in dogs and cats) contain no sensory fibres. The larynx possesses three functions, controlled by three distinct sets of muscles, all innervated by the recurrent nerves. These functions are: (1) Respiration. (2) Sphincter action, which closes the larynx and prevents the entrance of foreign bodies, and plays an important part in expulsive acts. (3) Phonatory action.

Stimuli applied to recurrent nerves produces adduction in certain animals (dogs), and abduction in other

<sup>1</sup> Continued from page 556.

animals (cats). Only a few experiments have been made in man, but, as far as they go, they seem to show that stimulation closes the glottis. Under ether or profound morphia narcosis, stimulation of the recurrent nerve produces opening of the glottis in dogs. Three hundred and twelve experiments were reported. Some of the animals were under the influence of chloral, chloroform, morphia, or ether. Under ether, dilatation was produced with weak currents, while contraction could not be produced with even the strongest current. As the dog begins to come out of the ether, dilatation cannot be induced with any current, while contraction is brought about by currents decreasing in intensity as the effect of ether passed off. A similar effect was observed in one case after the use of a large dose of morphia. After small doses of ether, stimulation produces two effects: first, vibration; second, closure. Under large doses of ether, four effects were observed, according to the intensity of the irritation, vibration, complete dilatation, mixed movement, and closure. After small doses of morphia, chloral, and chloroform, stimulation produces the same effects as after small doses of ether.

## DISCUSSION.

DR. F. I. KNIGHT, of Boston. Such different results are obtained in different animals, resulting from differences in size, weight, and other conditions, that they must be applied with a great deal of reserve to the human being. I saw some of the experiments of Dr. Hooper. In one case, I saw a failure to get the ether effect, which was attributed to the size of the dog. I saw a case in which a huge dose of morphia was followed by dilatation.

DR. S. W. LANGMAID, of Boston. In one of Dr. Hooper's experiments recently made, the skull was trephined and insensibility produced by pressing a plug against the cortex. In this case, dilatation was very marked under stimulation of the recurrent nerve. That is the only case in which I have seen dilatation similar to that which I think Dr. Donaldson describes. In some cases, I found it difficult to say exactly what I did see.

DR. ALLEN M. STARR, of New York. I recently had an opportunity to see, in Paris, some experiments by Charcot on hypnotized individuals. It is well known that, in this state, slight percussion of a nerve will produce contraction in the muscles supplied by that nerve. In one of these cases, slight stroking in the course of the recurrent laryngeal nerve over the trachea, below the larynx, produced such adduction of the vocal cords, and so interfered with breathing, that it became a question whether it would not be necessary to resort to tracheotomy.

DR. F. H. HOOPER, of Boston. We have been trying to get this effect with feeble stimuli, which Dr. Donaldson describes, but have been unable to do so. The only point on which we disagree is with reference to the effect of weak stimuli in unanesthetized animals. I have done a number of experiments, following the method of Dr. Donaldson, but have not gotten his results.

## AFTERNOON SESSION.

## CERTAIN MEASURES FOR THE RELIEF OF CONGESTIVE HEADACHE,

by DR. WILLIAM GLASGOW, of St. Louis.

The most severe symptoms in this condition are the pain and sense of constriction of the forehead. If the

pain is analyzed, it will be found that it is of two kinds: one gives a dull sense of fullness and occasional throbbing over the temple; the other is of the sharp, lancinating character so generally known as neuralgia.

At times, both of these varieties are present in the same case. In the one there is fullness of the vessels, and in the other disordered nerve-action. Both varieties are often due to the same pathological condition of the nasal chambers. During congestive headache, if we examine the nose, we find the cavernous bodies are full and tense. The degree of tenseness corresponds to a certain extent to the degree of headache. The method of treatment which he had adopted during the past four years had been the local abstraction of blood. A knife is not required; a simple prick is sufficient. In many cases the relief is immediate. The operation may have to be repeated in a month or two. He has seen few cases in which permanent relief had not followed a repetition of the operation from two to six times. The amount of blood drawn rarely exceeds an ounce. A number of illustrative cases were cited.

## DISCUSSION.

DR. J. N. MACKENZIE, of Baltimore. The paper goes to prove certain views which I have stated with reference to turgescence of the turbinated bones during the menstrual periods. I think that a number of headaches occurring during menstruation are due to congestion of the turbinated bones. Some years ago, I advised that, in acute coryza, an incision be made in the turbinated tissues with a sharp-pointed bistoury.

DR. C. C. RICE, of New York. My experience is somewhat different from that of the author. So far as chronic hypertrophic catarrh is concerned, I have come to look in these cases of headache for hypertrophy over the middle turbinated bone, pressing against the septum. I have seen many such cases. There has not been much congestion, but simply contact. In these cases I have used the galvanic cautery, and have not tried to draw blood. I have had the best results from this treatment. I think that it is sufficient to cause counter-irritation without bleeding.

DR. HARRISON ALLEN, of Philadelphia. I am more in accord with the last speaker than with the author. The trouble may come from the turbinated bones, but I have attributed it to pressure effects. We know that when the septum is deviated it is usually with the convexity to the left, but if a careful examination is made, it will be usually found that there is in the upper part a deviation in the opposite direction. This brings it in contact with the middle turbinated bone. The proper treatment is to separate the parts. I do not hesitate to etherize the patient, introduce the finger, and push the septum into place. In one case, a lady came to Philadelphia with a complication of disorders. There was astigmatism and also a lacerated cervix. She was under the care of an oculist and of a gynecologist. Each of these gentlemen attributed the trouble to the condition belonging to their special department. She had reflex headaches which was so severe as to lead to a fear of mental aberration. On examining the nose I found the condition referred to above and insisted that the headache was due to the trouble in the nose. I etherized the patient and separated the parts with the finger. The headache entirely disappeared.

DR. C. E. SAJOURS. While the lesions described

by Dr. Allan may be found in a number of cases I am more inclined to consider headaches originating in the nose as due to hyperæsthesia. I think that this is proven by the effect of light cauterization, and the treatment of Dr. Glasgow also goes to show that by depleting the cavity he reduces the stretching and pressure on the nerves and therefore reduces the hyperæsthesia.

DR. F. H. BOSWORTH, of New York. It is a fact that in many cases where we find contact between the middle turbinated bone and the septum there are no symptoms that can be referred to this condition. Judging from analogy we have in no other portion of the body neuralgia caused by the contact of mucous surfaces. In the vagina and urethra, we have mucous surfaces in contact. We may, however, safely say that it is a proper course to pursue to put the nasal cavity into a condition as near normal as possible.

DR. W. C. GLASGOW, of St. Louis. The paper said nothing at all about hypertrophy. No one recommends bleeding for hypertrophies, for these do not bleed. The fulness of the cavernous sinuses is simply the sign of the fulness of the frontal sinuses. I do not regard it as the cause of the trouble. I take blood from this part simply because this is the most convenient place to do it.

#### A CASE OF LEUCOPLAKIA. RECOVERY,

was the title of a paper by DR. W. C. GLASGOW, of St. Louis. It was read by the title.

#### DISCUSSION ON THE TREATMENT OF LARYNGITIS IN PROFESSIONALS WHO ARE UNABLE TO REST.

DR. J. SOLIS COHEN, of Philadelphia, opened the discussion. I do not know that I am any better able to treat these cases without rest than are others. Sometimes a professional will consult me with hoarseness, the result of laryngitis, and want to use his voice in a few hours. The best method to accomplish this that I have found has been the administration of a sharp emetic and then let the patient rest until the time of the performance, sucking pieces of ice and keeping a cold compress to the neck. In chronic laryngitis, I have found nothing of the same service as the use of a weak solution of sulphate of zinc, two grains to the ounce, used in a spray apparatus. In the intervals of the play, the patient may inhale a little compound tincture of benzoin if he finds that he is hoarse. Another remedy of considerable service is the use of a respiratory with turpentine, terebene or eucalyptol, or something of that kind. I sometimes direct the patient to sprinkle a little turpentine on the floor of the bedroom. I am, however, not aware of any special method which is adapted to this class of individuals.

DR. T. A. DEBLOIS, of Boston. I have had some experience with these cases, and have endeavored to keep up the systematic use of sulphate of zinc, but I have found that the hoarseness continues unless the voice is rested. I have occasionally had to treat vocalists who could spare a few hours, and I have found excellent results from the use of nitrate of silver, and the most disastrous results from the use of cocaine. There seems to be a certain amount of relaxation following the use of muriate of cocaine. I think that it may be said that in these cases unless there is rest there is no cure.

DR. BEVERLY ROBINSON, of New York. My ex-

perience with the class of cases under discussion would lead me to believe that so far as the acute cases are concerned there are milder measures than the use of an emetic. I have found under these circumstances that the use of tablet triturates of chloride of ammonium, repeated as often as once every fifteen minutes, is one of the most efficient methods of overcoming the difficulty. For local application I do not think that there is anything better than the carbolyzed spray. In the chronic form of laryngitis in vocalists, I believe that we cannot obtain much information from the appearance of the mucous membrane. In these cases I have often found the membrane red, and this may continue after the trouble with the voice has disappeared. I believe that here the trouble is chiefly in the neuromuscular apparatus. I have found the internal use of a good wine of coca with the application of a faradic current to the neck very useful. The faradism should be repeated once or twice a day.

DR. F. H. BOSWORTH, of New York. I think that there is no such disease as laryngitis, as that term is used to mean an inflammatory process. The seat of the disease is not in the larynx, but I think that it is in the nasal passages. If you apply cocaine to the nasal mucous membrane, causing contraction of the blood-vessels and follow this by the use of chromic acid, thus eliminating the cold in the head, it will usually be found that the laryngitis has disappeared. Relaxation has been spoken of as following the application of cocaine. Although I have used the drug in many cases, I have seen this result in only two, and they were cases of hay fever. My method of using cocaine is to suspend it in fluid cosmoline and direct the patient to spray the nose and throat with it.

DR. C. E. SAJOCS, of Philadelphia. I have treated many cases of this trouble. The action of cocaine in laryngitis is pernicious. I have used it in a four and in a ten per cent. solution, and every time that I have done so, I have had occasion to regret it. In cold in the head cocaine is useful, but it should not be used within four hours of the time when it is desired to use the voice. In the majority of the cases of chronic laryngitis the condition is due largely to fatigue. I have found that the use of quinine and nux vomica internally with the external use of a weak faradic current are the best measures to employ. I also think coca wine advantageous.

DR. W. C. GLASGOW, of St. Louis. In this class of cases, I have devoted myself entirely to the larynx and have not treated the nose. I employ applications of carbolyzed iodine to the larynx. This is a soothing application and relieves congestion. It also acts as a stimulant and enables the person to keep at his work, but it does not cure the condition.

DR. NORRIS J. ASCH, of New York. I think that the best way to treat the acute cases is that which we pursue in other acute cases, which is the treatment suggested by Dr. Cohen, with the omission of the emetic. The employment of muriate of ammonia is useful. I give it in solution in compound liquorice mixtures which contain a little tartar emetic. The chronic cases are more difficult to treat, because the patients cannot quit work. I have found nothing equal the application of astringents. I have used the spray in some cases, but more good is done by the use of the brush. The solution which I most frequently used is one of perchloride of iron, thirty to sixty grains to the ounce. Where a person has to use the

voice in a few hours, a single application will put it in good condition temporarily. Another point to be considered is that those individuals live usually irregular lives, drinking wine and eating heartily. There is therefore nearly always some hepatic trouble which requires attention. I do not believe that it is possible to put the larynx of a singer in perfect order as long as he has to work.

Dr. F. H. HOOPER, of Boston. In these professions there is sometimes an alteration in the quality of the voice the result of over-exertion. Here there seems to be want of tension in one vocal cord. To relieve this I have used electricity outside with the internal use of the aromatic spirits of ammonia, thirty to forty drops in half-a-glass of soda-water.

Dr. J. N. MACKENZIE, of Baltimore. I think that Dr. Brewster is to a great extent right with reference to the dependence of laryngeal disease on nasal trouble. I think that the vast majority of cases of laryngitis are associated with disease of the nasal passages, and upon the recognition of this fact, depends the successful treatment of many cases of chronic laryngitis. While I admit the existence of chronic primary laryngitis, I consider that the majority of cases are due to disease higher in the respiratory passages. I would give a caution with reference to the indiscriminate use of cocaine in diseases of the nose and throat. I should never use it just before a person was going to use the throat. The sensation which it produces in the larynx is only next to that of hanging. In the nose the effect is very pleasant, provided some of the solution does not trickle into the nose or larynx.

Dr. B. F. WESTBROOK, of Baltimore. While it is true that many of these singers and elocutionists suffer from strain and over-work, it is probable that, in the majority of cases, the seat of the whole trouble is in some derangement of the digestive apparatus, which predisposes to these affections. I think, therefore, that an emetic or active purgative is indicated in many of these cases. After the emetic, I give small doses of the mineral acids, frequently repeated, say one or two drops of dilute muriatic or nitric acid, repeated every hour.

(To be continued.)

#### AMERICAN MEDICAL ASSOCIATION.

THIRTY-EIGHTH ANNUAL SESSION, CHICAGO, JUNE 7TH, 8TH, 9TH AND 10TH, 1887.

##### FIRST DAY'S SESSION.

THE Thirty-eighth Annual Session of the American Medical Association convened June 7th, in Central Music Hall, Chicago, with a very large attendance.

Dr. CHARLES GILMAN SMITH, the Chairman of the Committee of Arrangements, called the Association to order shortly after eleven o'clock, when Dr. S. J. McPherson offered prayer. Dr. Smith introduced Mayor Roche, who made the following address of welcome:

MR. PRESIDENT AND GENTLEMEN, Representatives of the Science of Health and Life: In the name of the citizens of Chicago, I welcome you to this city, distinguished for the large number of able and eminent members of the medical profession, and for the exemplification, in all the avocations of life, of the precept: "Whatsoever thy hand findeth to do, do it with thy might." Your mission, to preserve health and re-

move disease, to prolong life and make it a blessing, is a beneficent and noble one, worthy of all honor, and, though you have not yet succeeded in overcoming death, you have robbed it of half its terrors.

The present generation has seen great progress in medical science, and the medical profession, I think, has kept pace with the other learned professions, if it has not even excelled them, in original investigations and practical discoveries for the benefit of mankind. When in health we laugh at the doctors, and sometimes enjoy a joke at your expense. But in sickness you are our hope and refuge, and to the worn and wasted patient, just struggling back to life from the gates of death, you are like "the shadow of a great rock in a weary land."

The interchange of ideas and experience, and the discussion of theories and experiments by large bodies of educated men gathered from different and distant sections of the country, by which the individual thoughts and knowledge of each becomes the common property of all is a comparatively modern outgrowth of Society, and must contribute greatly to the interest and usefulness of the medical profession, being full of promise for the future. These gatherings for mutual comparison and consultation minimize differences, soften asperities, cultivate the amenities, strengthen the humanities, stimulate inquiry and investigation, extend the horizon of mental and moral vision, enlarge the boundaries of human knowledge, and tend to the unification, improvement and well-being of the whole community. Gentlemen, I come here as the official representative of a great and hospitable city, whose latch-string is always out, to emphasize the welcome of Chicago to this large, intelligent and representative convocation of a profession whose chief occupation is to save life and not destroy it, and whose cardinal doctrine is that a sound mind in a sound body is essential to the best performance of the duties of this life, and a great help in fitting men for the life hereafter.

Dr. Charles Gilman Smith then read the programme of the session, and introduced the President, Dr. ELISHA A. GREGORY, of St. Louis, Mo., who delivered the Annual Address, the subject being,

##### CELL ANTAGONISM,

which forms the foundation of symptomatology and pathology, conjoined with cell changes, the basis of pathological anatomy, embracing at once the universe of life and all the possibilities of life, disease being but one of multitudinous phases of life.

In concluding, Dr. Gregory said: I need scarcely remind you, gentlemen, that we shall have with us, after a few weeks, the medical men of all nations. Soon we shall extend the hand of friendship to those with whom we have heretofore been united in interest and sympathy in the cause of science. We know that everything is being made ready and that success is assured. Again you will join me, I know, in the declaration that a hearty American welcome awaits their advent, and that the ninth meeting of the great congress will be memorable in the history of its organization.

##### SANITATION OF EMIGRANT SHIPS.

Dr. A. N. BELL, of the *New York Sanitarian*, read a report on the above subject, which should have been presented at the meeting of the Association last year.

The report dwelt upon the manner in which the laws are evaded, and also upon the incompetency of the physicians who are carried by ocean steamers. The report advocated the appointment of a competent assistant medical attendant upon vessels carrying more than six hundred persons in passengers and crew, and that physicians shall give their services free of cost to passengers and seamen alike, and that medical officers shall be compelled to attend to sanitary examinations of the vessels, and to see to it that passengers' and seamen's quarters shall be kept in a proper sanitary condition; that each vessel shall carry a competent medical steward and a good and sufficient supply of medicine; that physicians of vessels shall be compelled to make a report upon every case of disease or imbecility on boards of vessels of which they have charge to the health officer of the port in which they arrive, in order to prevent the landing of persons who may become charges upon the State. There should be such laws enacted by Congress as would prevent the introduction of diseases which might prove epidemic; also, to prevent the fearful mortality which now occurs among emigrants who are imported to these shores by various steamship lines. A resolution was adopted forwarding a copy of the report to the Secretary of the treasury, to Congress and to the Senate at the next session.

DR. ROBERTS, of Nashville, Tenn., read some resolutions condemnatory of an article in the daily press, which were subsequently tabled.

DR. BRODIE, of Detroit, moved that a section on dermatology and syphilography be created. The motion prevailed.

DR. GASTON, of Atlanta, Ga., from the special committee on inoculation as a prevention of yellow fever, to memorialize Congress, presented the report. From investigations which had been made in various countries the committee had been convinced that there was merit in the inoculation process as a preventive of the epidemic of yellow fever. The committee had endeavored to secure an appropriation from Congress of only \$10,000 to carry on the work, which had been refused.

#### SECOND DAY. MORNING SESSION.

The session was opened with prayer by Rev. Dr. Gunsalus, of Plymouth Church, after which Dr. Charles Gilman Smith invited the members to an exhibition of the police patrol ambulance service on Michigan Avenue, near the Leland Hotel, at nine o'clock.

The Board of the Journal of the Association reported that Dr. N. S. Davis, would continue as its editor during the ensuing year. The paper had been a success. Dr. Davis rendered a full account of his stewardship.

DR. N. S. DAVIS presented the report of the special committee on changes in the plan of organization and by-laws of the Association. It was an exceedingly lengthy document, and the amendments proposed were that the general committee or council should be composed of two members from each State and Territorial medical society entitled to representation by delegates and from the medical departments of the United States army, navy, and marine hospital service. The term of the general committee was fixed for two years. The general committee is named for the nominating committee; the board of trustees is to consist of nine

members, three of whom shall be members of the general committee. Several minor amendments to the by-laws were also suggested.

DR. VON MANSFELDE, of Nebraska, moved to adopt the report, with the amendments to the constitution and by-laws. This occasioned a lengthy discussion upon the question whether amendments to the constitution could be adopted by a *vire-voce* vote. Dr. Bell, of Brooklyn, N. Y., moved that as the question had already been before the Association for one year, and duly considered, that the amendments should therefore be now adopted.

The Association at this stage got into an entanglement of motions, points of order, etc., and the president, though a famous physician, could find no palliation for the muddle into which the meeting had brought itself. Finally, some one moved to table Dr. Bell's resolution. The chair forgot all about this motion, and put the question upon adoption or rejection, which resulted in 272 votes for, and 232 against. The chair declared that a decision had been reached in this matter, and that the amendments had been passed.

The following committee on nominations was announced: Alabama, W. C. Cross; Arkansas, G. C. Ewing; California, J. W. Robertson; Connecticut, W. H. Whittemore; District of Columbia, J. M. Toner; Florida, M. B. Phillips; Georgia, A. G. Whitehead; Illinois, E. P. Cook; Indiana, T. B. Harvey; Iowa, William Watson; Kansas, W. L. Skene; Kentucky, D. S. Reynolds; Louisiana, T. G. Richardson; Maine, D. E. Marston; Maryland, T. B. Evans; Massachusetts, E. W. Cushing; Michigan, William Prodie; Minnesota, J. A. McGaughey; Mississippi, T. A. Trotter; Missouri, J. M. Allen; Nebraska, W. M. Knapp; North Carolina, E. Grissom; New Hampshire, J. W. Parson; New Jersey, Lott Southard; New York, Darwin Colvin; Ohio, X. C. Scott; Pennsylvania, E. A. Wood; South Carolina, Thomas Legarn; Tennessee, J. B. Murfee; Texas, R. W. Park; Vermont, S. H. Griswold; Virginia, L. M. Nash; Wisconsin, J. K. Bartlett; United States Navy, D. Bloodgood; United States Marine Hospital Service, H. M. Goldsboro; Dakota, E. M. Darrow; New Mexico, Russell Bailey.

DR. J. S. LYNCH, of Baltimore, delivered his address as Chairman of the Section on the Practice of Medicine, which was listened to with marked attention.

The address was devoted to a glance at some of the discoveries or pretended discoveries, advances or hoped-for advances in the departments of medical science presided over by the speaker, not of the last year alone, but of the past few years. Antipyretics were discussed, and Dr. Lynch said:

Unquestionably the means of safely reducing and keeping down morbidly high temperatures constitute the most powerful weapons we possess in combating a large majority of the diseases to which mankind is heir. As I grow older and my experience enlarges, I become more and more convinced that fever is the lethal agent which destroys life in almost every disease in which that functional derangement is present. Whether in specific diseases or common inflammations, it is most frequently the morbid high temperature by its wasting destruction of tissue, the arrest of nutrition, and the associated derangements of function that determine the fatal result. Of course, in the so-called specific fevers it is the sole destructive agency.

In consumption (which in temperate climates de-

stroys nearly one-sixth of the population) it is the accompanying fever and its grade which determine the duration of the disease. Ninety cases in a hundred of pulmonary consumption die from asthenia long before the destructive processes going on in the lungs have deprived the patient of a sufficient amount of his respiratory apparatus to destroy his life. He dies, not of apnea, but of asthenia. Even in ordinary inflammation it is usually the fever that kills, and not the destruction of the organ inflamed, while the fever, although perhaps at first directly caused by the inflammation, reacts upon it and continues and intensifies it.

Until a very few years ago we had but a single agent that could be used successfully as an antipyretic, and this was so uncertain and so irritating to the gastric mucous membrane that it often failed us, and still more frequently could not be tolerated in doses sufficiently large to do its work. Indirect antipyretics of great activity we possessed in *veratrum viride*, *aconite* and *digitalis*, but these were too energetically poisonous to be safely used on all occasions. Aporetics—that is, medicines which increased heat-loss—we had in abundance, but these could not be continued long, for, although the nervous system may be protected from the directly injurious effects of heat by them, they did not arrest the too active combustion going on, and the patient died of exhaustion almost as soon as if left alone. We may haic pe on our steam boiler and thus prevent the formation of steam, or perhaps cause its recondensation as soon as formed, but we do not stop the combustion of coal in the furnace underneath. And so, too, we may by bathing, sponging, or sweating, keep down the temperature of the body externally, but the combustion is still going on internally—not quite so rapidly perhaps, but still at a sufficient rate in protracted fevers to produce final exhaustion and death. What we wanted, then, was something more certain and effective than quinine, less disagreeable to the stomach, and less injurious to the nervous system, and free from any poisonous effect, that would put out the fire by stopping combustion—an antipyretic.

With antifebrin Dr. Lynch had had but a very limited experience; he recognized its merits, however.

In antipyrine, with which his experience seems to have been extraordinarily fortunate, Dr. Lynch thinks we have such an agent. He began its use in 1881, in all diseases attended with fever, and his estimate of its value may be inferred from the statement that since that date he has not seen a single person die of enteric fever, scarlatina, or measles, only one of croupous pneumonia (seen too late), and that the duration of cases of phthisis seems to be very nearly doubled. In acute inflammatory rheumatism it seems to be scarcely less efficient than sodium salicylate. The dose should be about one gramme repeated at first every hour until three doses have been taken, and afterward every three or four hours. It is very soluble in water, has a slightly pungent and bitterish taste, and rarely excites nausea. If it should do so, it may be given in lime water or combined with other alkalis.

Strophanthus and sparteine were noticed, but neither of these cardiac stimulants had given satisfaction in the practice of the speaker.

The rest of the address occupied itself with tuberculosis, its nature and treatment. The conclusion was drawn that it is not a contagious and infectious disease, and while it cannot be denied that infection may and

probably does set up consumption in those who have suffered either from catarrho-pneumonia or scrofulosis, we must remember after all that it is bad hygienic surroundings which cause the pathological lesions which constitute the basis of fully ninety per cent. of all the cases of consumption we meet with, and invite the injurious action of the pathogenic microbe which brings to a fatal termination lesions which might otherwise remain quiescent for many years, and even be not inconsistent with a fair degree of longevity. Here, then, is a field in which we can work for the good of our common humanity.

In regard to Bergeon's treatment of pulmonary phthisis by gaseous enemata, Dr. Lynch can report nothing favorable: he thinks there is nothing in it except money to the sharks and charlatans that are unfortunately so numerous in our profession. While the antiseptic or rather the aseptic treatment may have a certain value in surgery and in obstetric, in medicine it must always remain an impossibility. For, admitting all that is claimed as to the agency of microbes in setting up and keeping up disease processes, it must be remembered that they are biologically as high in the plane of life, and, if all experiments can be believed, have a higher resisting power than the cells which compose the living elements of our tissues. Any germicides, therefore, which can destroy the one must inevitably also destroy the other.

After the paper of Dr. Lynch had been read, the general session adjourned to meet at three o'clock in the afternoon.

(To be continued.)

## Recent Literature.

*Dermatitis Venenata: An Account of the Action of External Irritants upon the Skin.* BY JAMES C. WHITE, M.D. Boston: Cupples & Hard. 1887.

"The number of native plants or those introduced into the United States which are capable in some degree of injuring the skin, is, as above stated, far greater than is generally known." This extract may be taken as the text of a book which could only have been written by one who was a trained botanist as well as dermatologist. The introductory chapter gives a clear and succinct description of the various cutaneous lesions which occur in connection with dermatitis venenata, together with directions as to its proper treatment. The rest of the book is taken up with the consideration more or less in detail, according to their several importance, of all substances, to which may be attributed upon trustworthy evidence, the property of exciting cutaneous inflammation by reason of their irritant action upon the human skin. This list includes more than sixty plants; it comprises also, various substances, coming under the head of drugs and chemicals, many of which are applied to the skin with therapeutic intent; and certain animals, such as the medusae and polyps among marine organisms and the various insects, parasitic or otherwise, which are capable of exciting cutaneous irritation. The work is a distinct and valuable addition to the literature of the subject, and much credit is due to the publishers for the excellent manner in which the book is issued from the press.

G. H. T.

THE BOSTON  
Medical and Surgical Journal.

THURSDAY, JUNE 16, 1887.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,  
94 BOYLSTON STREET, BOSTON, MASS.

THE TEETH OF LOUIS XIV AND THE REVOCATION OF THE EDICT OF NANTES.

PHYSICIANS of a historico-philosophical cast of mind have often amused themselves with thinking what changes in the world's history might have been made had the maladies of sundry great men received different treatment, and hence possibly experienced a different termination. In a previous volume of the JOURNAL, we have referred to the ingenious speculations of Dr. MacDonnell, in a paper before the Athenæum Club, regarding the diseases of certain English monarchs. James the First died, as it seems, for the want of a shilling's worth of quinine, and the disease from which the much-married Henry VIII suffered might, in the light of modern treatment, have been prevented from affecting his unborn children.

"Catherine of Aragon," says Dr. MacDonnell, "might have been the mother of many Tudors, the Stuarts would never have been heard of, the Reformation would have been postponed, and Henry himself would have been talked of to-day as a model father and husband. Queen Mary's cruel disposition, if not the actual result, was certainly intensified by the disappointment which followed her fruitless marriage. . . . A course of aloes and iron might have changed the course of events in England and Europe." *Per contra*, we are lost in reflection as to what would have been the result had the mothers of the Neros and the Caligulas, on the one hand, or of the Augustuses and the Alfreds on the other, been, in their youth, subjected to the present fashionable surgical treatment for ovarian neuralgia.

This line of thought is suggested by an article in the *L'Union Médicale* for April 2d, by Dr. T. David, entitled "Les Dents de Louis XIV." Its facts are obtained from the reports of the physicians and dentists of that grand monarch. This reign of seventy-two years, the longest recorded in authentic history, fell to the lot of a man of phthisical ancestry (his father died from consumption)—a man who suffered from anal fistula, and who drank deeply of the most exhausting pleasures and vices. Yet he did a vast

amount of work, especially if we include his diplomatic plotting and scheming. It happened, however, that the teeth of the monarch were very unsound. Before he reached middle age, all the teeth of his upper jaw were gone, or reduced to carious stumps. His appetite did not reduce itself in conformity with his diminished facilities for the preliminary treatment of his food. Hence dyspepsia, and from this origin, suspicion, malice, cruelty, and all the foul brood of that dreadful monster. No cunning artificer was at hand to construct the substitute, comely in appearance and admirable in function, for the frail product of nature. Throughout the memorable year 1685 the king suffered from osteitis of the upper jaw, following the extraction of a stump, and to this was added suppuration of the antrum and decomposition of the pus. On one occasion, the actual canter was applied fourteen times in one day to the carious alveolus. Who can fail to see the necessity, in order to overcome the repugnance excited by his loathsome condition in the ladies of the court, of more abundant largess of gold and jewels, and hence, of greater oppression of his subjects to gain the requisite money? A few grains of gold, applied at the proper time and place by a skilful dentist, might have saved the value of millions, which were spent to make the king's attentions endurable to his favorites. The saving of this money would have quenched that spark of discontent, which, after smouldering for a century, burst forth in the flames of the Revolution.

But the great crisis in which the failure of dental and surgical science culminated occurred, according to Dr. David, in October of that year of suffering and self-loathing, when the grand monarch signed the Revocation of the Edict of Nantes, and 400,000 Protestants, secure for nearly a century in their religious liberties, were driven forth from France, to carry the knowledge of all manner of handicraft to enrich the coffers of other nations. Had the king been less foul-mouthed, he had surely been sweeter spoken towards the Huguenots. Little wonder that what he breathed out was threatenings and slaughter!

Fortunately, perhaps, for our peace of mind, it is given to but few of us to bear, as medical men, the undivided and heavy responsibility of the physical welfare, and so of the mental state or intellectual activity of the world's great men. The physicians who failed to regulate the deranged digestion of Carlyle must have been overwhelmed if they had any premonition of the widespread consequences of their failure. When Mr. Gladstone has had an attack of laryngitis on the eve of one of his great efforts in the Commons, the doctor who had charge of his vocal apparatus might well feel that upon his skill rested the political future of Ireland for the next half-century. When Bismarck finds himself getting too "sleek and fat" to be dangerous, and resorts for help to his physician, it makes much difference to European politics whether the latter person succeeds in relieving the chancellor of fifty or of two hundred and fifty pounds of flesh. What wonder, then, that Dr. Schweininger magnifies his office!

## WHY PHYSICIANS SHOULD MAKE CAREFUL NOTES OF THEIR CASES.

THE advantages which accrue to the professional man from making accurate memoranda of his cases, are threefold: first, to himself, second, to his patient, third, to the medical confraternity generally.

The habit is one which is highly beneficial to the physician, leading him to greater accuracy in investigation and in diagnosis, and giving him a better command of all the details of the case. It cannot fail to be of benefit to the patient, for the latter will profit by the greater knowledge which his physician acquires of his malady, and the certainty that a case well understood is better treated. A physician who studiously makes notes, and keeps a careful account of his cases, will be more likely to communicate valuable practical experience to the medical profession, than one who is careless about preserving the important facts that continually come under his observation.

The amount of time requisite for writing such daily observations respecting each patient, as are necessary to give precision and continuity to the record of the case, is not considerable, especially if the record be made about the time of the visit; and a suitable memorandum book for the purpose may always be at hand. Many physicians waste in profitless loafing, hours of leisure which might better be spent in reading up their cases, or in doing something to add to the general stock of knowledge of the profession. Some with mental powers and educational attainments of a high order, get into a careless, slipshod, and haphazard way of diagnosis: devote no time to writing up their cases, and too little time to watching and mastering the symptoms; and suddenly, some morning, awake to a realization, that the supposed case of ephemera was a bad form of typhoid, that the disease diagnosed as pneumonia was pleurisy with effusion, that the simple attack of colic was one of peritonitis, and the trifling case of angina, one of malignant scarlatina.

How much valuable experience is lost to the world, because physicians under whose observation come hosts of rich and varied facts (and under this category we must include great numbers of country practitioners), fail to record, communicate, or even definitely to remember what they have witnessed, is, of course, an unknown, but immeasurably vast quantity.

No better example can be appealed to of what can be accomplished by the kind of industry which we have above commended, than that of the late Dr. Austin Flint, whose whole life was devoted to the perfection of his own powers, the promotion of the highest welfare of his patients, and (as an ulterior but by no means secondary end), the improvement of the profession of which he was a member. The twelve large manuscript volumes of record of cases which he has left, without which his numerous treatises on medicine, now become classical, could never have been written, attest his indefatigable care, diligence and painstaking, all of which, it is true, were supplemented by an almost invariable physical health and vigor.

Many physicians complain of their want of time to accomplish anything outside of their ordinary daily routine of drudgery, but it is a significant fact that those men who have had the least leisure, have done the most good work of the kind to which we have alluded. We refer to the recognized leaders, whose professional duties have always been most arduous and exhausting—the Jacksons, the Brodies, the Watsons, the Trousseaus, the Charcots, the Flints, of medical literature—who have found time amid their pressing labors to record facts of personal observation and experimentation, and compose those works which have been, in an eminent degree, helpful to the present generation of medical men, and will never cease to have an influence on professional opinion and practice.

## MEDICAL NOTES.

—The small-pox has increased, both in the number of cases and in the severity of the malady, in the eastern portion of Cuba. At Havana the cases are few.

—The President of the Key West Board of Health reported by telegraph, under date of June 5th, that "yellow fever has ceased to be sporadic, and absolute segregation of patients in hospital impossible, as friends conceal cases, and violently oppose removing sick; therefore, for these reasons, the Board will declare the disease to be fast assuming an epidemic character." The Secretary of the Treasury has authorized the employment of nurses and guards to assist the Board of Health at the Barracks Hospital. Total cases to June 10th, 22; deaths, 8.

—Dr. I. Vroz, writing to the *New York Medical Journal* from the Virgin Islands, British West Indies, where he has had a large experience with malarial fevers of various types, speaks most highly of the use of permanganate of potash. He says: "Most of the inhabitants of the district where I practised, lived in thatched huts, badly ventilated, with the natural soil for the floor. As the country abounds in rivers, and rain is constant, they were very damp. The food eaten consists of carbohydrates and boiled fish—a diet which, with their surroundings, certainly renders them unfit to resist disease. I was consulted by women with fever and amenorrhœa or dysmenorrhœa due to exposure, and malarial anemia or toxæmia. It was to them that I first administered permanganate of potassium, and it cured them not only of their uterine symptoms, but of their malarial fever also. I afterward gave it to men and children, and with very interesting and successful results. The usual dose was from half-a-grain to a grain, in water, three times a day. In private practice I give five grains of pepsin after the dose, to prevent the nausea, which is the only drawback to the use of the drug. Since my appointment as medical officer of the Virgin Islands, I have been using the same treatment here with good results. I have not heard or read of its having been used before for malarial fevers. As to the *modus operandi* of the permanganate, I will say but little,

and that what I know—namely, that, as a germicide, it is one of the best, and one that is harmless even in strong solutions."

## BOSTON.

—A boy was killed at the "South Cove" Boston, last week, by coming in contact with a wire for supplying a Brush electric light. It is not known whether he took hold of the wire or fell against it. It was carried over a coal shed of the Boston & Albany Railroad and ran from a dynamo operated with an eighteen horse-power engine to supply nineteen lights, each of two thousand candle power. It is said that the wire was not only not insulated but that it was in appearance just like ordinary telegraph wire. The accident happened just before dark at the moment when the light was turned on. The boy was held in contact with the wire several minutes and was burned deeply through his clothing at one point on his leg, with a smaller burn on the neck. He died before reaching the hospital. The employee who finally released him from the wire was himself powerfully effected by the current and did not recover from the shock for several hours.

## NEW YORK.

—On the eighth of June, Governor Hill listened to an argument from Mr. W. A. Purrrington, counsel of the New York State and County Medical Societies, in favor of the bill regulating the practice of medicine and codifying the laws of the State, which was recently passed by the Legislature at Albany. It simply requires that before beginning the practice of medicine in New York State, one should have studied his profession and passed for his degree at a chartered school or before one of the Regent's Boards, and it does not prohibit any system of practice. It codifies existing laws and makes clear doubtful sections, and the new matter contained in the measure is as follows: *First*, a provision of forms for registration and indorsement, to secure uniformity and prevent mistakes often arising from the careless methods at present in vogue, by reason of which the records are untrustworthy and the aim of the law defeated; *second*, the enumeration of the following offenses, all of a fraudulent nature, are made punishable as prescribed by the Penal Code, in analogous cases; perjury in false affidavit of registry, counterfeiting, buying, selling, and altering diplomas, or falsely personating another practitioner, and practising after conviction of felony; *third*, a civil action for a penalty given by the Revised Statutes, the reason being that when a person is practising under forged papers, purporting to be issued by a foreign university which he has never attended, as in a pending case, it is not possible for the prosecution under existing laws to issue a commission to take testimony.

Those who would be punishable, if the bill become a law, are persons making false affidavits in order to register; those who fraudulently buy, sell, counterfeit and use diplomas to deceive the public; those who falsely personate other practitioners, appropriating their names and credit; convicted felons who, as in

the case of one now in New York, may serve as many as three terms of imprisonment for criminal malpractice and return to renew their illegal procedures.

## Correspondence.

## MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

CHICAGO, June 10, 1887.

MR. EDITOR.—The meeting of the American Medical Association which closed at noon to-day may fairly be regarded as a successful one. Upwards of one thousand delegates and permanent members were registered during the four days of the meeting. The *personnel* of the body was about the same as usual; but regular attendants on the meetings of the Association in former years note the relative decrease in the proportion of eminent men of the profession, especially from the East, in attendance upon this meeting. The Association assembled in something of a mass meeting, and occasionally, as was witnessed on the second day when the report of the Committee on Changes in the organization was under consideration, it assumed the appearance, by its uproar and confusion, of an old-fashioned town-meeting.

The President's Address on "Cell Antagonism," was a scholarly production; it was a most interesting and graceful, even poetic, exposition of the pathology of the hour.

The work of the Sections, it is generally conceded, has been exceptionally good from a scientific standpoint, which is certainly hopeful for the future of the body. It is manifestly the aim of those who are guiding, or trying to guide, the destinies of the organization to have more work done in the Sections and less in the general meetings, to the end that it may have less the character of the mass-meeting and more that of a scientific body. In this they are succeeding. Hereafter the formal addresses by the Chairman of Sections are to be delivered before their respective Sections and not before the full convention, while three set addresses before the general body are to be read by prominent men specially and formally invited, on medicine, surgery, and "public medicine" respectively.

The report of the Committee on Changes in the Organization embodied propositions for changes in the Constitution which must lie over a year, on the sensible ruling of the President, although the Association had practically voted at the turbulent session that they were adopted then. They ought to be adopted next year, and probably will be. One provides for a permanent general committee to make all nominations and consider nearly all general matters of business coming before the Association—it takes vital matters out of the hands of the mass-meeting, where they are as likely as not to be spoiled, and places them in the hands of a smaller body of fairly-selected men who may justly be entitled to the designation of a deliberative body.

Another provides for a Board of Trustees of nine, to have charge of the properties (the *Journal* and the treasures) of the Association. The Trustees are to be nominated by the General Committee. If these amendments are adopted the general meetings of the Association will be nearly deprived of opportunities to do mischief by taking hasty, ill-considered and hot action on momentous subjects, to be regretted with chagrin afterward.

The Association voted this morning that hereafter there shall be a dinner provided as one of the entertainments at the meetings, and that members who attend shall pay a fixed fee which shall be different for those who do and those who do not have wine—when a member registers his name and pays, he is to designate to which of these classes he desires to belong, and the banquet hall is to be arranged for the accommodation of this arrangement. It is an amusing fact, that was not lost sight of, that the proposition was made by Dr. N. S. Davis, a life-long, unflinching enemy of the use of wine anywhere, at any time.

The social features of this meeting have not been neglected. On the first evening there were four receptions

given by citizens, only one of whom was a layman, and on the third evening there were three similar receptions. But the general reception at "Battery D.," on the second evening is conceded to have been the most useful as well as the most enjoyable. It was in a hall sufficiently large to enable every person attending the meeting to move about with perfect ease and meet every other person. It is doubtful if the dinner of next year will take the place of this grand reception as a means of bringing members together in a social and helpful way.

It was a pleasant surprise to most of the visiting members that the *Journal* and *Examiner* and the *Standard* issued daily editions containing commendable full reports of the proceedings. This is especially true of the latter, which not only had good reports of the sessions, but editorial comments upon them that were always able, if at times a little severe. Its editor, Dr. Kiernan, wields a trenchant pen which he can dip in gall when he tries to.

Notwithstanding the animadversions of the *Standard*, the writer heard almost no complaints of the work of the Committee of Arrangements, and other committees, but abundant thanks and praise for them all, and especially for the genial and courteous Chairman of the Committee of Arrangements, Dr. Charles Gilman Smith.

As to the *Journal* of the Association, not a word was heard in favor of any change in its place of publication or its editorial management. The editor's report was a favorable showing of progress for the publication, and the members were generally aware of an improvement in its character during the past year, so the satisfaction at the disposition of this item of business was general.

The Association wanted a thousand dollars for the International Congress, although Dr. Davis protested that half that sum ought to do, as all the balance in the treasury was needed to improve the *Journal*. This was the only reference to the Congress in the proceedings of the meeting.

## REPORTED MORTALITY FOR THE WEEK ENDING JUNE 4, 1887.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2,005; under five years of age 765; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 361, consumption 301, lung diseases 205, diphtheria and croup 120, diarrhoeal diseases 89, measles 33, cerebro-spinal meningitis 14, typhoid fever 21, malarial fever 21, whooping-cough 15, scarlet fever 20, erysipelas eight, puerperal fever seven, small-pox (New York) four. From scarlet fever, New York 16, Philadelphia and Brooklyn four each, Baltimore two, Boston, District of Columbia and Pittsburgh one each. From typhoid fever, Philadelphia six, Pittsburgh four, Boston three, New York and Brooklyn, two each, District of Columbia, Nashville, Chelsea and Taunton one each. From malarial fever, New York eight, New Orleans six, Brooklyn three, District of Columbia two, Philadelphia and Charleston one each. From whooping-cough, New York six, Philadelphia three, Baltimore and District of Columbia two each, Boston and Pittsburgh one each. From cerebro-spinal meningitis, New York three, Philadelphia, Dis-

trict of Columbia, Fall River two each, Boston, Newport, Milwaukee, Taunton and Brockton one each. From erysipelas, Brooklyn five, New York two, Philadelphia one. From puerperal fever, Milwaukee two, New York, Boston, Pittsburgh, Providence, and Cambridge one each.

In the 26 greater towns of England and Wales, with an estimated population of 9,244,060, for the week ending May 21st, the death-rate was 20.3. Deaths reported 3,594; infants under one year of age 805; acute diseases of the respiratory organs (London, 289), measles 237, whooping-cough 158, scarlet fever 48, diarrhoea 47, diphtheria 22, fever 19.

The death-rates ranged from 12.3 in Wolverhampton to 31.1 in Manchester; Birmingham 18.3; Blackburn 21.4; Brighton 18.1; Hull 18.5; Leeds 16.8; Leicester 14.2; Liverpool 23.4; London 19.0; Newcastle-on-Tyne 27.9; Nottingham 17.5; Portsmouth 19.3; Sheffield 18.3; Sunderland 14.9.

In Edinburgh 15.7; Glasgow 24.6; Dublin 25.4.

The meteorological record for the week ending June 4, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending Saturday, June 4, 1887.	Barom- eter.	Thermometer.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall. Duration, Hrs. & Min. Amount in Inches.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 4, 1887, TO JUNE 10, 1887.

FRYER, B. E., major and surgeon. Granted two months' leave on account of sickness, permission to apply for an extension. S. O. 23, Division of the Pacific, May 28, 1887.

FRYER, B. E., major and surgeon. Granted sick leave for one month. S. O. 28, current series, Division of the Pacific, amended by S. O. 29, Division of the Pacific, June 2, 1887.

TREMAINE, W. S., major and surgeon. Sick leave still further extended two months, on account of sickness. S. O. 129, A. G. O., June 6, 1887.

BROWN, PAUL R., captain and assistant surgeon. Granted leave of absence for four months. S. O. 136, A. G. O., June 2, 1887.

APPEL, A. H., captain and assistant surgeon. Granted leave of absence on surgeon's certificate of disability, six months. S. O. 127, A. G. O., June 3, 1887.

WOOD, LEONARD, first lieutenant and assistant surgeon. Ordered for temporary duty at Fort Huachuca, A. T.; relieved from duty at Headquarters' Department, Arizona. S. O. 126, A. G. O., June 2, 1887.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING JUNE 11, 1887.

VAN RUYEN, W. K., surgeon. Ordered June 8th, for examination preliminary to promotion as Medical Inspector.

ROBINSON, SOMERSET, medical inspector. Ordered June 20th, before a Retiring Board convened at Mare Island, Cal.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING JUNE 4, 1887.

GOLDSBOROUGH, C. B., surgeon. Detailed to represent the Service at the meeting of the American Medical Association, at Chicago, Ill., June 6, 1887. June 1, 1887.

BANKS, C. E., passed assistant surgeon. When relieved to rejoin station at Boston, Mass., May 23, 1887.

NORMAN, SEATON, assistant surgeon. When relieved to rejoin station at Cape Charles Quarantine, May 26, 1887.

#### BOOKS AND PAMPHLETS RECEIVED.

Ninth Annual Report of the Trustees of the Danvers Lunatic Hospital, for the Year ending September 30, 1886. Boston, 1887.

ANEMIA. By Frederick P. Henry, M.D., Professor of Clinical Medicine in the Philadelphia Polyclinic, etc. Philadelphia: P. Blakiston, Son & Co. 1887. (Reprint.)

Report of the Committee on Disinfectants, Presented at the Fourteenth Annual Meeting of the American Public Health Association, held at Toronto, Canada, October 5-8, 1886.

Phosphorus-Necrosis of the Jaws. By J. Ewing Mears, M.D., Professor of Anatomy and Clinical Surgery in the Pennsylvania College of Dental Surgery; Surgeon to St. Mary's Hospital, Philadelphia, etc. Philadelphia: Wm. J. Dornan. 1886. (Reprint.)

Lomb Prize Essay. Healthy Homes and Food for the Working Classes. By Victor C. Vaughan, M.D., Ph.D., Professor in University of Michigan. Concord, N. H.: Republican Press Association. 1886.

Transactions of the Association of American Physicians. First Session. Washington, D. C., June 17 and 18, 1886. Francis Delafield, M.D., President, James Tyson, M.D., Secretary, James T. Whittaker, M.D., Recorder. Philadelphia, 1886.

The Practitioner's Handbook of Treatment, or the Principles of Therapeutics. By J. Milner Fothergill, M.D., Physician to the London Hospital for Diseases of the Chest, etc. Third American from third English edition. Philadelphia: Lea Brothers & Co. 1887.

Public Health. The Lomb Prize Essays. Award made at the Thirteenth Annual Meeting of the American Public Health Association, Washington, D. C., December 10, 1885. With an Appendix. Second Edition. Concord, N. H.: Republican Press Association. 1886.

Sur un Nouveau Traitement de la Métrite Chronique et en particulier de l'endométrite par la Galvano-caustique. Chirurgie intra-utérine, par le Dr. G. Apostoli, professeur libre de Gynécologie et d'Electrothérapie à l'école pratique, etc., avec 9 figures dans le texte. Paris: Octave Doin, Editeur. 1887.

Dose and Price Labels of all the Drugs and Preparations of the United States Pharmacopoeia of 1880; together with many Unofficial Articles that are frequently called for as Medicines or used in the Arts for the use of Pharmacists, Physicians and Students. Second Edition. By C. L. Lochman. Philadelphia: Dunlap & Clarke. 1887.

Elementary Microscopical Technology. A Manual for Students of Microscopy. In Three Parts. Part I. The Technical History of a Slide from the Crude Materials to the Finished Mount. By Frank L. James, Ph.D., M.D., President St. Louis Society of Microscopists, etc. St. Louis: St. Louis Medical and Surgical Journal Company. 1887.

Practical Lessons in Nursing: Maternity, Infancy, Childhood, Hygiene of Pregnancy, Nursing and Weaning of Infants; the Care of Children in Health and Disease. Adapted especially to the Use of Mothers or those intrusted with the bringing up of Infants and Children, and Training-Schools for Nurses, etc. By John M. Keating, M.D. Philadelphia: J. B. Lippincott Co. 1887.

Earth as a Topical Application in Surgery. Being a full exposition of its uses in all the cases requiring topical applications admitted in the Men's and Women's Surgical Wards of the Pennsylvania Hospital during a period of six months in 1883. By Adinell Hewson, M.D. Second Edition. With four photo-relief illustrations. Philadelphia: The Medical Register Co. 1887.

Elements of Botany. Including Organography, Vegetable Histology, Vegetable Physiology and Vegetable Taxonomy, and a Glossary of Botanical Terms. Illustrated by nearly five hundred engravings from drawings by the author. By Edison S. Easton, A.M., F.R.M.S., Professor of Botany, Materia Medica and Microscopy in the Chicago College of Pharmacy. Chicago: G. P. Engelhard & Co. 1887.

Cyclopædia of Obstetrics and Gynecology. The Pathology of Labor and the Uses of Ergot; being Volume Three of a Practical Treatise on Obstetrics. By Dr. A. Charpentier, Adjunct Professor at the Faculty of Medicine, Paris. Translated under the supervision of, and with notes and additions by Egbert H. Grandin, M.D. In four volumes. 248 fine wood engravings. New York: Wm. Wood & Co. 1887.

## Lecture.

### METHODS OF RESEARCH IN MEDICAL LITERATURE.<sup>1</sup>

BY JOHN S. BILLINGS, M.D.,  
Surgeon, United States Army, Washington, D. C.

WHEN I promised to speak briefly at this meeting on medical bibliography, it was not because I had anything new to say on this subject, but because it seemed possible that a few remarks might start a discussion by the medical writers and teachers of this Association as to the methods which they have found useful, and as to what they think can and should be done here to facilitate this kind of research. From the days of Galen to the middle of the seventeenth century, bibliographical work was the most important business of the medical teacher. The great majority of the writers of the Middle Ages busied themselves, not so much with observation of facts, or with experimental inquiry, as with seeking to find out what Hippocrates, Galen, Avicenna, and other old masters had said about the matter. When the discovery was made that, in order to determine the precise anatomy of a part, the function of an organ, or the results produced by a disease, it was best to look for one's self, instead of consulting the fathers, and when this discovery had become popularized, bibliographical and historical research fell for a time into neglect. Within the last fifty years, however, there has been a revival in interest in the collection of medical libraries and in historical research, which last has become a necessity in many cases, if one would avoid doing useless work. Attempts to learn what has been done, or said, or thought, by our predecessors are due to widely different needs, and may be pursued by widely different methods.

As specimens of subjects with regard to which bibliographical work is most frequently called for, I give the following:

(1) To gather and compare the records of all reported cases of particular forms of abnormality, disease, or injury. The rarer and more anomalous the abnormality or the disease, the more important it is to find the widely-scattered records.

(2) To obtain statistical data with regard to the circumstances affecting the prevalence of a certain disease, the relative frequency of particular symptoms, and the comparative merits of different modes of treatment, or the results of special operations.

(3) To obtain information as to details of methods which have been tried in experimental physiology, pathology, or pharmacology, and as to the results; in order to avoid waste of time in devising apparatus, or in trying methods, which have been already found worthless, or to obtain suggestions as to new modes of experimentation.

(4) To trace the origin and development of medical organization in a particular city or country, or to gather materials for a biographical sketch of some celebrated physician, or for the history of a medical society.

(5) To obtain data for a comparison of the laws and customs of different countries affecting medical education, or the right to practice, or the care of the insane, or public hygiene, etc.

In literary research for biographical purposes, or to trace the development of theories or institutions, the

work must be done mainly by the writer himself; and, while at the commencement he may be greatly helped by systematic works of medical bibliography, he will soon find himself wandering off into all sorts of curious by-paths and out-of-the-way corners, into which he is led by obeying the golden rule for this kind of work, namely, to "verify your references." In the first book which he consults he will probably find two or three references, which will indicate to him as many different books or articles which he will wish to consult. When he gets these, each of them will probably give a few more references, to be hunted up in like manner.

Meantime, it will not be an unprecedented or very remarkable occurrence if, in the course of his reading, he stumbles over several interesting points not precisely connected with his original quest, but still having some relation to it, and which it seems a pity not to look up while he is about it, so he makes note of these, and of the references connected with them, and sends for a fresh lot of books. He finds, also, that some of his quotations are erroneous, that "some one has blundered or plagiarized," and proceeds with a sense of refreshment and satisfaction to hunt down the culprit. And so the work expands, for, as Teufelsdröckh remarks, "any road will lead you to the end of the world." To those who like this sort of literary work it has a great fascination, and there are few educated men who do not enjoy a short hunt of this kind, if they have time and facilities for it. From a strictly utilitarian and merely pecuniary point of view, the results of such bibliographical excursions are not usually very remunerative, but they afford capital mental exercise, and occasionally result in the production of some really interesting and valuable additions to medical literature.

Men engaged in this line of research do not usually, except just at first, care much about subject catalogues or indexes. They know what books they want to see, and the catalogue which interests them most frequently is a catalogue of authors in alphabetical order. The questions which they ask of the librarian are something like the following: Have you got such a book in the library? Who is the author of a book having such a title? John Smith published a book about such a date — what is its title? I want to see all the books that Peter Brown wrote or edited. How many editions were published of "Jones's Surgery," and what translations were made of it? When did the *Ohio Medical Repository* begin and end, and who were its editors? These are all simple questions, which almost any physician can answer for himself by the aid of good, ordinary author-catalogues.

If the question is as to a collection of laws regulating medical practice in Brussels, or the number of supplements to the "Catalogue of the New York Hospital," some physicians might be troubled a little to find the desired information in an author catalogue, not knowing the rule that a government or corporation is considered to be the author of its laws, reports, etc., and that, therefore, Belgium is the author of the first book, and the New York Hospital of the second.

But while a simple alphabetical catalogue of authors will serve many purposes in bibliographical research, and is, perhaps, the one most used by the librarian, there are many points on which it fails to give the desired information, and for which bibliographical lists or subject-catalogues are desirable; and just here

<sup>1</sup> Delivered before the Association of American Physicians, Washington, June 2, 1887.

a few definitions may be useful. By a bibliography I mean a list of titles of books, and of references to articles or paragraphs which relate to the subject in hand. By a critical bibliography I mean a list in which shall be indicated those books or articles which are of real value, as containing some addition to knowledge. In many, perhaps most, cases, such lists are best published in chronological form, thus indicating the successive dates on which new information was given; but, in making them, the use of separate slips or cards, arranged in alphabetical order, is the most convenient. The more complete such lists can be made, the more valuable they are, but often too much time is wasted in attempts to make them absolutely perfect. The great thing to be kept in view is to make them accurate as far as they go, and one of the best means of doing this is to indicate distinctly for each title quoted as to whether you yourself have or have not seen and examined the book. It should be constantly borne in mind that the proper object in giving bibliographical lists is not to impress the reader with the extent and variety of the author's research, but to give him the means of verifying the author's statements, and of pushing the research further. It is analogous to giving details of methods used in an experiment in physiology. Hence the references given should not be too condensed. They should be so clear, that from them it shall be easy to find the books, and for this reason I ask your attention to the desirability of using a uniform system of abbreviations of titles of journals and transactions in referring to them, and venture to suggest that the set of such abbreviations given at the beginning of Vol. VII of the Index Catalogue may be found useful for this purpose.

I have elsewhere called attention to the essential differences between medical bibliography, properly so called, and subject-catalogues of particular libraries. No matter how large and complete a medical library may be, its subject-catalogue can never form anything like a satisfactory medical bibliography; it only makes a good foundation for one.

On the other hand, when you wish to use bibliographical lists prepared by others, you have usually much difficulty in finding some of the books referred to; while the references which you do find in a subject-catalogue of a given library, can at all events be verified by visiting that library. The labor of preparing bibliographical lists, and of research, after one has been furnished with such a list, is in many cases very considerable, and such work can usually only be carried on to advantage in a large library. As this is preëminently an age of division of labor, it is natural to apply this principle also to bibliographical research. There are many cases in which what may be called mechanical bibliography and literary research may be used to excellent advantage, and the field for this kind of work will expand in the future. It is especially applicable in those cases, indicated in a preceding part of this paper, in which it is desired to compare the records of cases and operations, and to prepare statistics. It is often much better for the busy practitioner to have this work done for him than to attempt to do it himself, and especially is this the case if he does not easily read other languages besides his own. It is true that by employing others to do such work, he loses both pleasure and instruction, but the field of professional work and study is now so wide that it is impossible for any one man to cover it all, and he

must be content with coöperative effort. It is also true that such work is not only sometimes expensive, but that it is often difficult to tell beforehand what it will cost. There are several physicians in Washington who are willing to undertake work of this kind in the library of the Surgeon-General's Office, for physicians at a distance who cannot conveniently visit this city, and their charge for such work, hunting up references, making abstracts, translations, etc., is one dollar per hour. You can readily see that there can be no very definite relation between the time occupied and results produced: a half-page abstract may require two hours to prepare, or it may be done in ten minutes, and sometimes it may cost less to purchase a pamphlet than to obtain an abstract of it in this way. Nevertheless the demand for this kind of work is steadily increasing, and a supply will arise to meet the demand.

In order to obtain satisfactory results from bibliographical work done in this way it is necessary that the points to be looked up shall be stated as concisely, and as precisely, as possible; in other words that the person who requests the search shall know clearly what he wants. I have elsewhere called attention to this by quoting the warning which is printed on the title-page of the Washington City Directory, namely, "If you want to find a name in this directory, you must know how to spell it," which is the same as the old Latin proverb, "*qui nihil affert, nihil refert.*" When I receive a letter stating that the writer is about to prepare a paper for his county medical society; that he has selected for his subject, tumors of the liver, or locomotor ataxy, or the causes of insanity in modern times; and that he would be glad to have as complete a list of references as possible to all articles, reports of cases, or statistics connected with these subjects,—and that his paper must be prepared in two weeks,—I know of course that what he wants is one of the recent encyclopedias of medicine, and advise accordingly. The problem is not always so simple, however, and I must confess that I am sometimes very much puzzled as to what to reply to some of the queries which I receive. Nevertheless, we are all learning gradually how to use medical libraries, and in a few years more I predict that the wonder will be how we ever got on without them.

I have here a few of the books which are most used in this library for subject-references, a list of which is appended to this paper. I include in this list the catalogues of certain libraries for reasons already given. For other valuable works consult in the index-catalogue the headings, Bibliography Medical, Biography Medical, and Medicine, History of. With regard to the index-catalogue of this library, with which you are all more or less familiar, I may say that its most important defects are those of omission, that is, the failure to give under subject-headings all the references to books and articles actually in the library which really belong there, and it requires a little practice to enable one to get the best results from it.

There are many books and journal articles which different men would classify under different heads, and in most cases when one consults the index for a particular subject he finds more references than he cares to be bothered with, although the list is almost always incomplete owing to the fact that we have not yet obtained all the medical books which have been printed. We are, however, making fair progress in this direc-

tion; I think we now have over three-fourths of all medical books which have any special value or interest, and at least two-thirds of all the medical literature which has been printed.

In consulting the index on any given subject it will usually be found possible to select from the rather formidably large mass of titles those which are most likely to be of interest by giving a little attention to author's names, to the place and date of publication and to the number of pages and plates, if it is a journal article. The cross-references should be consulted, and under the headings to which these will guide you will often be found new cross-references which should also be looked up.

Since the year 1800, about one-half of the medical literature which has been published, consists of medical journals and transactions. Nine-tenths of the demands made on this library are based on references to this class of literature, and it is therefore of the greatest importance in medical bibliography. The number of medical journals and transactions now received by this library, excluding those devoted to pharmacy and dentistry, is over seven hundred, and it has been steadily increasing for the last five years.

If we take Plouquet's *literatura medica digesta* to be as complete an index of the medical literature in existence at the beginning of this century as the index catalogue is of the medical literature now in existence, it is evident that the number of references has more than quadrupled during the present century. Nine-tenths at least, of it, becomes worthless, and of no interest within ten years after the date of its publication, and much of it is so when it first appears. Of that which is really new and good a large part is pretty promptly made use of by systematizers and compilers, but there is also a considerable portion which we cannot use in our present state of knowledge but which become valuable building material hereafter. To get this roughly sorted out, classified and labelled, so that it can be found when wanted, is the object of indexing; to bring it into use is the object of bibliography.

One of the most useful pieces of work which could now be undertaken for the benefit of medical writers and investigators would be the preparation of a dictionary of critical bibliography of medical bibliography, in which should be indicated for each subject in alphabetical order a reference to where the best bibliography relating to that subject can be found. This could only be well done by a coöperation of a number of writers, each taking a special field.

I have not attempted in this brief paper to eulogize bibliography or to comment on the desirability that there should always be a few men interested in the study of the history and literature of medicine. I think that you will all agree with me that they may be sources of much pleasure, and that this alone is a fairly good reason for giving them some attention, and for exerting the influence of the profession to make it possible in at least one place in this country to carry out such studies with a full supply of material.

And while the librarian is in one respect only a sort of hod-carrier, who brings together the bricks made by one set of men in order that another set of men may build therewith—he is apt to take quite as much pride and satisfaction in the resulting structure, provided it be a good one, as if he had built it himself; and he has constantly unrolling before him a

panorama which, though at times a little monotonous, contains as much wisdom, humor, and pathos, as any other product of the human intellect with which I am acquainted.

## Original Article.

### OBSERVATIONS ON THE USE OF ANTIPYRINE AND THALLIN IN THE TREATMENT OF TYPHOID FEVER.<sup>1</sup>

BY FRANCIS MINOT, M.D.

*Horsey Professor of the Theory and Practice of Physic in Harvard University; Consulting Physician to Massachusetts General Hospital.*

IN the autumn and winter of 1885-86, and in those of 1886-87, I ordered antipyrine and thallin in twenty-four cases of typhoid fever in the Massachusetts General Hospital, with the object of ascertaining, as far as possible, to what extent they could be relied upon as remedies of positive value in the treatment of that disease. An abstract of each case was made, and compared with the temperature-chart, the latter including, in a considerable number of cases, the hourly varia-

<sup>1</sup> Read before the Association of American Physicians, Washington, June 2, 1887.

tions after each dose, as well as the regular morning and evening range. The main points for investigation included:

- (1) The dose of each drug required to produce a depression of two or three degrees of temperature.
- (2) Conditions affecting the action of the drugs.
- (3) Effects on the condition of the patient.
- (4) Effects of the drugs in fatal cases.
- (5) Effects of antipyrine and thallin when given in continuous doses.
- (6) Comparative effects of antipyrine and thallin.

The twenty-four cases include all the typhoids that were submitted to the action of these drugs in the wards under my charge during these two terms of service.

The regular treatment of typhoid fever in these wards was expectant. A considerable proportion of the cases required no special interference. The patients were carefully fed, chiefly with milk, plain or peptonized, and occasionally with animal broths. All were regularly sponged several times daily with plain water, either cold or tepid. In cases where there was much prostration, brandy or whiskey was given, in doses ranging from one to two drachms, every three or four hours, to one ounce every hour. The patients were very lightly covered, often with only a sheet. Very few required opiates.

Antipyrine or thallin were given only when the temperature rose above 102.5° (Fahr.).

#### DOSE.

The doses employed varied according to the age of the patient, and the degree of pyrexia. From twenty to thirty grains of antipyrine were generally given to an adult, eight grains to a child of twelve years, and five grains to a child of three years, whenever the temperature reached three-and-one-half degrees (Fahr.) above the normal standard. If retained by the patient, this invariably had the effect of reducing the temperature two or three degrees, and sometimes more, in the course of one or two hours; the mercury then rose during the same length of time, till it reached its original level, or a degree below that. The same results followed the use of thallin in much smaller doses. In one case (an adult), two grains reduced the temperature from 105.7° to 101.2°. In general, four grains of thallin were given to an adult. When given in continuous doses, every three or four hours, for example, it was found, in some cases, that after one full dose, much smaller subsequent ones were sufficient to maintain the temperature at a given level. In the case of a patient twelve years old, after one dose of two grains of thallin, a single grain, given from twice to six times daily, was sufficient to keep the temperature at a moderate level.

#### CONDITIONS AFFECTING THE ACTION OF THE DRUGS.

It was observed that antipyrine and thallin acted most promptly, and with most permanent effect, when given at, or just before the end of the fastigium, thus giving rise to the suspicion that the improvement would have taken place had the medicine not been given. There is no doubt that this suspicion is just, so far as a permanent reaction is concerned. Inspection of the charts shows that, in general, antipyrine and thallin given during the fastigium reduced the temperature promptly, but only temporarily, except when they were given shortly before the lysis began (Susan Hamblet). In one case, however, that of a child three years old (J.

H. Frizzell), the fastigium was unusually short, and the chart shows an immediate and permanent reduction after antipyrine had been given. There was no doubt of the diagnosis in this case. In other cases, it seems probable, from inspection of the chart, that the temperature was controlled, or prevented from rising higher, although no permanent depression was effected, though, of course, this could not be demonstrated. In general, however, it was found that the more severe the symptoms, including high fever, the more difficult it was to maintain a moderate temperature by means of antipyrine or thallin. So far as I could discover, there were no other conditions which interfered with their action.

#### EFFECTS UPON THE PATIENTS.

The general effect of antipyrine and thallin upon the patients was almost always favorable, and no case was observed in which the exhibition of either drug was followed by any worse results than sweating and occasional vomiting. It was noted, in a large number of cases, that the patients slept tranquilly after taking them. No special prostration or exhaustion was recorded. Generally, it is reported that no change took place in the character or rate of the pulse. In many cases, the patient, from being restless or delirious, became tranquil and rational. In almost all the cases, it is reported that the patients were more comfortable after taking the medicine. These effects were more marked and more lasting when the drug was given during the defervescence than during the fastigium, but still they were observed at all periods of the disease. The favorable effects were decidedly more noticeable in children than in adults, and the drugs were remarkably well borne by children.

#### ANTIPYRINE AND THALLIN IN FATAL CASES.

I examined with care the records of the six fatal cases, in order to ascertain whether the result could be attributed, in any of them, to the refrigerant medicine. The first case was that of Lizzie Prime, domestic, twenty-seven years old, who entered the hospital December 14, 1886, with typhoid symptoms, signs of bronchitic inflammation, a pre-systolic cardiac murmur, and weak pulse. Three days after entrance she had a dose of antipyrine, which was repeated on the two following days, when the temperature became normal, and the medicine was discontinued. During all this time, the weak and irregular condition of the pulse continued. On the eighth day after entrance, signs of œdema of the glottis appeared, and at eight o'clock in the evening the trachea was opened, but no relief was afforded to the dyspnoea, and the patient died soon afterwards. Although no unfavorable effects following the administration of the antipyrine were recorded, I cannot but think that the condition of the pulse was such that the case was an unfavorable one for the exhibition of the drug. As no autopsy could be obtained, the cause of death could not be certainly ascertained: since the trachea was opened before death, œdema of the glottis could not have been the only cause. Stimulants were freely given throughout the case.

The next fatal case was similar to the last in respect to the condition of the pulse. Joseph Farrell, twenty-six years old, waiter, entered the hospital October 1, 1886, and died October 11th. He had been in bed seven days before entrance. He took several doses of antipyrine, of five to ten grains each, daily for nine

days, after which the temperature gradually fell to 99° on the day of his death. Throughout the case, the action of the heart was very feeble, and the lungs were œdematous. The density of the urine was 1012; there was a trace of albumen, with numerous hyaline and granular casts. *Post-mortem*, the muscular substance of the heart was found to be pale and translucent; the kidneys, on section, were pale, the cortex thickened, glomeruli distinct, and surrounding substance gray; spleen about four times the natural size, soft, and easily torn; great increase of pulp. The intestines showed the usual lesions. Stimulants were freely given throughout the case. No unfavorable symptoms which could be attributed to antipyrine were recorded, but the case was evidently not likely to be benefited by it.

The third fatal case, that of Louisa Smith, twenty-six years old, was one of relapse. Her mother and sister had typhoid recently, each had a relapse, and each had internal hemorrhage. Her husband, also, was convalescent from a "fever." The patient, who was much fatigued from nursing the others, and who also had a miscarriage at the fifth month, eight weeks previously, entered the hospital February 6, 1887, having been in bed two weeks with typhoid symptoms. The case was of moderate severity, and without special treatment the temperature gradually fell, and reached the normal standard on February 13th, the twenty-first day of the disease. February 17th, the temperature began to rise again, and after four days it reached 104°. On the sixth day of the relapse, one dose of thallin of four grains was given, which appeared to have a favorable effect, and was not repeated. February 28th, the eleventh day of the relapse, at 7 P. M., a sudden rigor occurred, with intense pain in the abdomen, vomiting, thready pulse, and all the symptoms of peritonitis from perforation, of which the patient died, March 3d, at 7 A. M. As only a single dose of thallin was given, which was followed by no unfavorable symptoms eight days before death from perforation, it is not probable that the drug had any influence in causing the fatal catastrophe.

Kate Murphy, twenty-one years old, entered hospital February 21st, and died, March 6, 1887. This was the fifth case of typhoid fever brought to this hospital from the same house, and the eighth person who had contracted the disease there, this season. Pale, chlorotic-looking; in bed three days before entrance. Temperature at entrance, 103.4°. It rose to 105.7° on the evening of February 25th, (eleventh day), and began to fall on the morning of the 27th, (thirteenth day). The decline continued till the evening of March, (nineteenth day), when it was at 98.5°. During all this time the symptoms grew worse and she died early the next morning. The cause of the failure of this patient appeared to have been diarrhoea, which set in on the fifteenth day, and was followed by delirium and exhaustion. She took six doses of thallin of two grains each, the last one seven days before her death.

Margaret Coffin, aged 54, entered the hospital October 16, 1886, and died November 11th. For six weeks before entrance she had been occupied in nursing a daughter with typhoid, and another daughter entered along with the mother, sick with the same disease. The symptoms began two weeks before entrance, and were threatening from the first. The temperature was very irregular, and at times as low as

97° without obvious cause—there was no hemorrhage. Diarrhoea was persistent. Treatment was chiefly by free administration of stimulants. November 6th, two grains of thallin were given at 5 A. M., the temperature being at 103°; it began to fall at once, and 8 o'clock was at the normal point. In an hour it rose rapidly to 102.2° and the dose was repeated. The next day the same dose of thallin was given at 10 A. M., with a similar result. No more was given, although the patient seemed more comfortable after the medicine. She gradually failed, and died at 2 A. M., November 11th, at about the thirty-sixth day of the disease.

The sixth fatal case was that of William Millis, twenty-four years old, who entered the hospital November 17th, and died November 25, 1886. In bed five days before entrance. He steadily grew worse until his death. The symptoms were stupor, delirium, and prostration. There was no evidence of serious lung or heart complication; but the condition of the urine was suspicious of previous renal disease. Thallin and antipyrine were thoroughly tried throughout the course of the disease, the former in doses of four grains, which readily reduced the temperature several degrees, though only for a short time. Antipyrine was given several times in doses of fifteen and twenty grains, smaller doses failing to act. Thirty grains were also given by enema twice, but without any effect at all. On the whole, the general effect of the antipyretics was thought to be favorable, it being noted repeatedly that after a dose had been given the patient was less restless, and more comfortable, notwithstanding a chill often occurred.

#### CONTINUED USE OF ANTIPYRETICS.

A few cases of typhoid were treated by the continued administration of antipyretic remedies. Either a single dose was given daily, or, as in most cases oftener than once daily. As an example of this method may be cited the case of John Swift, twenty-nine years old, who entered the hospital December 14, 1885, complaining for two weeks of lassitude and loss of appetite, and for one week of diarrhoea. The chart shows that the fastigium was just beginning at the time of his entrance. The temperature was 103°, and later the same evening 103.4°. He was much prostrated, and stupid, had abundant rose spots, enlarged spleen, gurgling in the right iliac region, etc. The next day he was delirious, trying to get out of bed, and twenty grains of antipyrine were given, after which he perspired freely, and became much quieter. The temperature was reduced from nearly 105° to 101°. After that he got two doses daily, of the same amount, except on one day when none was given; and it is remarkable that on that day only did the temperature rise above 103°. During the rest of the fastigium it varied between 101° and 102.5°. At the end of eight days the defervescence began, the temperature falling gradually and spontaneously, during five days, when it became normal, on December 31st, at about the twenty-fifth day of the disease. It is reported that he never had nausea or vomiting; the pulse remained unchanged after antipyrine; restlessness and delirium were much diminished.

In one case in which the temperature rose during the fastigium to 106° small doses (one and two grains) of thallin and antipyrine, sometimes one and sometimes the other, were given in a series of thirty-four doses, at intervals of from one to eight hours, with a

single dose of thirty grains of antipyrine, without unfavorable effect, and the patient recovered.

#### COMPARATIVE EFFECTS OF ANTIPYRINE AND THALLIN.

The study of the reports of the cases and of the temperature charts reveals but little difference in the effects of the two drugs; but soon after the introduction of thallin it was almost always employed in preference to the other, and the general impression derived from my experience in the two is that prolonged chill, excessive sweating, and vomiting were more frequently observed after the employment of antipyrine than of thallin.

#### CONCLUSIONS.

So far as trustworthy conclusions can be obtained from the comparison of so small a number of observations they would seem to be as follows:

(1) Antipyrine and thallin given internally have a remarkable power of reducing by several degrees the bodily temperature in typhoid fever within a period of from one to three hours, after which in most cases the temperature rises again in about the same length of time, sometimes to the original degree, but often not quite so high.

(2) The use of the drugs did not appear to give rise to any unfavorable effects upon the course of the disease, even in fatal cases.

(3) In general, the condition of the patient was more comfortable after the effect of the refrigerant medicine was produced; he was more tranquil, often slept, and frequently expressed himself as relieved.

(4) The refrigerant medication by antipyrine and thallin appears to have no specific or decided effect upon the course or issue of typhoid fever. In some cases the general condition was apparently relieved or improved throughout the course, but in most cases these drugs can only be looked upon as palliatives, often contributing to the patient's comfort, and perhaps indirectly promoting his safety.

(5) The failure of such efficient antipyretics as antipyrine and thallin to avert the fatal issue in many grave cases of typhoid fever shows that the danger does not consist in high temperature alone, but that the latter is rather an index of the abnormal condition which we call fever, though probably adding somewhat to the danger.

(6) By the internal use of antipyrine and thallin all the effects which are claimed for the treatment of typhoid fever by the cold bath are readily obtained without the trouble and inconvenience of the latter method, and without exposing the patient to the danger of exhaustion and shock consequent on the fatigue of removal from bed.

(7) These remedies may be given without danger to the youngest patient in suitable doses, and indeed their beneficial effects are more decided with them than with adults.

#### ADDENDUM.

Before concluding this paper, I wish to allude to the very favorable effect of refrigerant medicines in the treatment of the hectic of pulmonary consumption. Eight grains of antipyrine given daily at three or four o'clock in the afternoon has in my experience both in hospital and private practice been effectual in preventing the rise of temperature, the sweating and the flushing which are a source of so much discomfort to phthisical patients, especially during the period of soften-

ing, although the remedy appears to have no effect on the progress of the disease.

The chart which I will pass around, is that of F. W. Tolsom, eighteen years old, who entered the hospital January 23, 1886, with cough and muco-purulent expectoration, night sweats, loss of weight and strength, etc. The signs were dulness, broncho-vesicular respiratory murmur, bronchophony, moist crepitant rale, etc., in the right apex, extending in front to the third rib, and half way down the scapula behind. One dose of antipyrine was given the next day, but none on the two following days, during which the evening temperature ranged between 103° and 104°. Eight grains were then given daily at 4 p. m., for the remainder of his stay (13 days), during which time the temperature was greatly reduced and the hectic suppressed. The patient also gained two pounds in weight.

### Clinical Memorandum.

#### ATTEMPTED SUICIDE FROM THE INGESTION OF FIFTY-ONE GRAINS OF MORPHINE, THE GREATER PART OF WHICH REMAINED IN THE STOMACH THIRTEEN HOURS: RECOVERY.

REPORTED BY GEORGE M. MORSE, M.D., OF CLINTON, MASS.

IN the JOURNAL of May 12th is reported "A Case of Attempted Suicide by the Ingestion of Thirty-six Grains of Morphine, which remained in the stomach five hours." I have to report a still larger amount taken, and remaining a still longer time in the stomach.

May 25th, M. C., aged thirty-two years, was found by his boarding-mistress, at ten minutes past twelve, in his room, on the bed, unconscious. Dr. French was called, who sent for me, with the request that I would come immediately, and bring a stomach-pump. I arrived at the house at about 1 o'clock, p. m. We found the patient, a strong, well-built man, dressed with the utmost care and nicely, lying on the bed, which had not been slept in, unconscious, sweating profusely; pupils contracted to a pin's point; respiration very irregular, abdominal; lips purple, face cyanotic. On the table was found a bottle with Power's and Weightman's red label, containing, by weight, nine grains of morphine; in a goblet by side of bed, about two drachms of water, which tasted like a solution of morphine; also a sealed letter, directed to patient's wife, marked "deliver immediately—death." The bottle was apparently a new bottle, fresh from the apothecary; the tin-foil had not been entirely removed from the cork. In a vessel under the bed was found, as we judged, about two ounces of greenish fluid, containing food, the green color given, apparently, by garden-rhubarb. A lamp was burning in the room, indicating that the patient had been on the bed many hours. The lamp would ordinarily burn for twelve or fourteen hours; the oil was nearly exhausted.

The diagnosis was easily made out, namely, attempted suicide by the use of morphine, taken sometime during the previous night. Attempts, which were ineffectual, had been made by Dr. French to make him swallow coffee. He had also administered atropine hypodermically. While getting my stomach-pump ready, one-thirtieth-of-a-grain of atropine was injected. At 1.15 p. m., I removed ten ounces of

fluid, like, in appearance, the liquid found in the vessel, pumped back sixteen ounces of warm water, which I removed, and injected another pint of water, and removed that also. Having thoroughly rinsed out the stomach, I pumped in a pint of very strong black coffee. Flagellation of the face by a wet towel, and of the nates by a small cane, was kept up until a galvanic battery was obtained, one pole of which was applied to the epigastrium, and the other to the carotid triangle.

2.30 p. m. Pupils dilated a little; respiration improved; patient not so cyanotic. Flagellation caused corrugation of the superciliary and orbicularis muscles.

3.30 p. m. Patient very purple, entirely unconscious; pulse 140, respirations three per minute. We gave ten grains of caffeine. Galvanism was continued; the negative pole applied to lips and carotid triangle alternately. 5 p. m. Respiration improved; Cheyne-Stokes in character.

5.30 p. m. Caffeine, ten grains; galvanism continued.

6 p. m. Pulse 148, respirations twenty per minute.

9 p. m. Patient could be made to open eyes by shouting, shaking, and by applying the cane with considerable force to the nates. Caffeine every three hours; also galvanism intermittently.

2 a. m. Nurse said he waked up and became conscious. 9 a. m. Patient seemed quite conscious, but said his head felt light; vomited, and in the afternoon was quite delirious, saw snakes, etc.

He was well the next day, and gave this account of himself: At 11 p. m., May 25th, he retired to his room, took a bath, dressed himself in his best clothing—clean shirt, collar, white neck-tie, and white stockings—wrote the letter to his wife; put one-half the contents of an eighth-ounce bottle of morphine (which he had bought some days before) into a goblet of water, and drank it; filled the goblet with water and put more morphine in it, and drank of it occasionally until he became unconscious; the last drink he took made him sick, and he vomited once—what we found in the vessel.

There were nine grains found in the bottle, showing that he had taken fifty-one grains, and he said he wasted only what he vomited, and which we found in the vessel. According to his account, he drank about twelve ounces of water, in which were dissolved fifty-one grains of morphine. He vomited two ounces, so that there must have remained in his stomach for more than twelve hours more than forty grains of morphine. No estimate is here made of the contents of his stomach before taking morphine. There must have been considerable, as we found what appeared like garden-rhubarb in the matter pumped out.

It is to be regretted that no attempt was made to ascertain the amount of morphine pumped out, but, in the hurry and confusion, the whole was thrown away. The points of interest in this case are the large amount of morphine taken, the length of time it remained in the stomach before any attempt was made to remove or antagonize its effects, and lastly, the success of the treatment, namely, the stomach-pump, atropine, caffeine, galvanism, and flagellation.

This case, together with the case reported from Denver by Dr. Fisk, shows that however desperate the case may seem to be, however large the amount taken, or the length of time before treatment is commenced, persistent endeavors to relieve the patient

should continue so long as respiration can be kept up by the use of galvanism and flagellation. In short, every effort should be made to keep the patient alive until the poison has spent its force, or has been antagonized by the atropine and caffeine.

### Reports of Societies.

#### THE ONE HUNDRED AND SIXTH ANNUAL MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY, JUNE 7TH AND 8TH, 1887.<sup>1</sup>

##### THE ANNUAL DINNER.

Soon after one o'clock the traditional procession took up its line of march down Boylston to Clarendon Street, to Winslow's rink, where Caterer Weber had arranged over a score of tables covered with inviting delicacies. The skating-floor was well filled up with them, while on a platform in the front of the rink were more tables for the invited guests and the officers of the society. In the side-gallery were twenty-five musicians from the Cadet Band, under the leadership of J. Thomas Baldwin. Upwards of nine hundred Fellows sat down to dinner. The assembly was called to order by the Anniversary Chairman, Dr. William L. Richardson, of Boston, and grace was said by the Rev. Brooke Herford, of Boston.

The platform was occupied by the following gentlemen of prominence, besides the officers of the Society and the delegates from other societies: Gov. Ames, U. S. Dist.-Atty. George M. Stearns, the Rev. Brooke Herford, Col. T. W. Higginson, Asst.-Atty. Gen. H. N. Shepard, Surg.-Gen. A. F. Holt, Mr. Roger Wolcott, Drs. B. E. Cotting, H. W. Williams, G. H. Lyman, H. I. Bowditch, Alfred Hosmer, William Cogswell, G. C. Shattuck, G. B. Shattuck, Francis Minot, H. P. Bowditch, C. B. Porter, J. C. Warren, H. P. Walcott, John Homan, G. H. M. Rowe, and others.

The caterer's wares having been disposed of, Dr. Richardson began the later exercises of the day. After acknowledging his indebtedness to the efficient committee of arrangements, he proceeded with the introduction of the various speakers, as follows:

We are favored by the presence of several distinguished gentlemen whom I shall call upon to address you. Much, doubtless, to your disappointment, but at their earnest request, I have consented to give up the custom, sometimes followed at these annual dinners, of having long speeches. These to which I invite your attention will be brief. The first to speak will be the gentleman who, as our President, represents the Society — Dr. Thomas H. Gage, of Worcester.

To which Dr. Gage responded as follows:

MR. CHAIRMAN, I thank you, in behalf of your associates of the Massachusetts Medical Society, for these graceful and complimentary words. And, in the same behalf, I thank you and the gentlemen who have been associated with you in the Committee of Arrangements, for your untiring and every way successful efforts to make this anniversary meeting one of more than usual pleasure and profit. You have afforded us an intellectual entertainment of a high order; you have given us, under the auspices of a generous hospitality, an hour of pleasant social intercourse; and

you have in reserve a "feast of wit and reason" to which the vast audience here assembled is looking forward with eager expectation. Distinguished guests honor us by their presence, and eloquent speakers await your pleasure to address us. Nothing but the purely conventional requirement that I should be first to receive your summons and respond for those I have the honor to represent, stands now between your audience and its anticipated enjoyments. And I will, of course, be brief.

The year that has passed, since we were last assembled here, has been within our organization, one of harmony and peace. The Massachusetts Medical Society has been disturbed by no unwelcome topics of discussion, and by no discordant counsels. There has been nothing to distract attention from the great pursuits for which it was established by the fathers, and for which it still affords the highest encouragements and the amplest opportunities. Everything has favored a season of normal and healthful activity, and such a season we have enjoyed. It has been a year of general prosperity, and, in my judgment, of substantial and commendable progress. We have not startled the scientific world, it is true, by great achievement or remarkable announcement; but we have contributed to make such results possible in the future. We have gathered knowledge and experience and made them available for reference, instruction, illustration, and mutual improvement. We have invited and encouraged independent and original experiment and research. And we have examined, from time to time, under the light of full and free discussion, the facts and the theories we have thus brought together.

All along the line from Berkshire to Barnstable, this scientific activity has been kept up throughout the year. Communications of high character, showing care in the preparation, close observation of the phenomena of disease, excellent knowledge of the principles of medicine, and studious application, both at the bedside and in the library, have been the rule in all the District Societies. And the general character of the discussions they have elicited has been equally high and instructive. Here and there, to be sure, the stream of intellectual thought and endeavor has encountered in its course the old mossgrown obstructions of apathy, indifference, and inharmonious relations, and for a little space flowed sluggishly; but nowhere has it ceased. The great and useful work of encouraging and promoting, by associated effort, a knowledge of medicine and surgery, and a love of science, has gone quietly and prosperously on. And, as it has fallen under my notice, it has been, in its general scope and character, exceedingly practical. To a very large extent it has consisted of the presentation and discussion of cases, including not only those of an unusual nature and exceptional interest, but those also of commoner form, illustrating disease, casualty, and emergency, as they pass under every busy physician's daily observation and care. And the result has been the contribution of not a few new and useful suggestions in both theory and practice. And so in a very practical way great principles have been the subject of communication and discussion, and especially those that underlie the sciences of public health and the prevention of disease. Nearly all the societies have had under consideration the practical application of these to the public and domestic wants of the people.

In speaking of this practical feature of the year,

<sup>1</sup> Concluded from page 579.

which has been so conspicuous everywhere, I am inclined to illustrate it by citing a prominent instance, and I trust an allusion to a particular Society by name will not be anywhere regarded as making an invidious distinction. Circumstances of an unusual and very extraordinary nature have given the Norfolk District a remarkable opportunity for the study of an important class of injuries, and I wish to allude to the excellent use made by that Society of the scientific material thus thrown in its way. I refer to the experience afforded its members by the Bussey Bridge disaster, and to the systematic effort made by them to utilize their observations for the advancement of science. Should the methods, thus far developed, be by them still further pursued, and the cases of the injured be kept under observation, and from time to time reported and published, a contribution of valuable nature upon the vexed medico-legal questions that grow out of railway injuries may be expected to result. This circle of events, namely, the opportunity, the use made of it already, and the further use of it that seems to be promised in the future, will have afforded, when it is complete, a typical illustration of the capabilities of our District Societies for the most profitable kind of practical work.

But the organic act under which the Massachusetts Medical Society exists, and which provides for district organizations, mentions particularly the communication of experiments, as well as of cases, as a means of encouraging and promoting the acquisition of medical knowledge. By which is meant, I suppose, the communication of such experiments and researches in the field of science, as are undertaken with the purpose of discovering new truth, or of verifying the alleged discoveries of such truth by others. Now in the nature of things such communications as these are much less common than those of an immediately practical character. Not many of those

"Whose modest want of everyday  
The toil of everyday supplies,"

can afford the time or the means required for such exercises. And besides, few have the taste for such employments, and fewer still the knowledge of details, the special skill, and the mental discipline, necessary to make an attempt of this sort one of really scientific value. Yet even such communications as these, though far less abundantly than the others, the year has supplied. Contributions giving the results of independent and original research in the fields of bacteriology, histological pathology, and the specific poisons have been quite numerous, and exceedingly creditable, not only to the authors and observers, but to the societies they have represented.

Thus, Mr. Chairman and gentlemen, the year that has passed, since we were last assembled here, has been one of healthful activity, faithful endeavor, and useful results; and thus, substantially, it will pass into history, and become a companion of the many, all more or less illustrious, that have preceded it. Its opportunities are gone, and it is itself past recall. Let us waste upon it neither criticisms nor regrets. Another, equally inviting, and with the sublimest of possibilities, lies before us. Let us make the best of that.

DR. RICHARDSON then said:

The State of Massachusetts next claims our attention. We are honored on this occasion by the pres-

ence of the chief magistrate of the Commonwealth, a man of few words but who does not hesitate to act in accordance with what he thinks is right. I have the pleasure to introduce His Excellency, Governor Ames.

The GOVERNOR, who was enthusiastically received, spoke as follows:—

GENTLEMEN OF THE MASSACHUSETTS MEDICAL SOCIETY:—When I first became acquainted with the country doctor he combined in his person the professions of physician, dentist, and apothecary. In these later days, which are so distinguished by the division of labor, the doctor has become simply the physician, and he writes for you a prescription, and bids you go to the apothecary. Following the modern example, I have written my prescription for this occasion, which I will proceed to read to you:

Gentlemen of the Massachusetts Medical Society; It gives me great pleasure that in the rush of business in which I am now involved, I am able to come here, to express to you the kind feeling which the Commonwealth has for those who practice the healing art within her borders. It must be said, that as much as some of us, individually, dislike the doses which you prescribe, we cannot do without you. You are all-powerful with us when we are most in need of the sympathy of our fellow-men, and you use that power with such skill and discretion that the physician is often the best, as he is almost always the wisest, friend of the family. Time was, when the dominion of the sick-room was divided between the doctor, the clergyman, and the lawyer; but now no one disputes with you for preëminence in that place, unless it be the nurse, that modern adjunct to your profession, for which we cannot be too grateful to you. In whatever way one turns, one sees something which ought to evoke his gratitude to you. In public improvements, which tend to raise the standard of the general health, none are more active; in securing better lighting, improved ventilation, and thorough drainage for our homes and places of business, none take a greater interest. Indeed, you have become, and to our advantage, preventers of, rather than curers of, diseases and that life is lengthened, with all its opportunities and all its blessings, is largely due to your efforts. Again I greet you in the name of the Commonwealth, and repeat my assurance that in you she sees a body of men whom she delights to honor—for she has no more wise, useful, or patriotic citizens.

The chairman then resumed: Having thus recognized the State, we turn to pay our attention to the United States, and we are very fortunate in having with us to-day a gentleman who as the United States District-Attorney, fittingly represents the national government—the Hon. George M. Stearns.

MR. STEARNS spoke substantially as follows:

MR. PRESIDENT AND BROTHER DOCTORS: I don't think we take naturally to doctors. My first recollection of the doctor is of a large, imposing, solemn gentleman dressed in black, who drove a little black mare in a little black gig, and carried a pair of black saddlebags filled with medicaments of a dirty color, who smelt of camphor, and who, when he was called upon to administer to my ailments, when bribery and persuasion and threats had failed, seized me in his strong arms and held my nose while my mother turned his vile decoctions down my juvenile throat. But as we proceed in life I think the doctor keeps mounting higher and higher in our regard and esteem, for no

boy arrives at the age of ten years without resolving to be either a stage driver or a circus performer or a doctor. Not that they are kindred professions, but they are allied to the one object dearest above all others to the juvenile mind, and that is a horse. No other five letters convey to a boy so much attraction and pleasure as h-o-r-s-e.

But he still further rises in our esteem when upon other occasions we see him in the sick-room, when we see him with his fingers upon the wrists of our wives and our children; and as we watch him and a smile comes over his face he becomes a harbinger of hope and an angel of gladness. I know of no one who brings more sunshine into places of sorrow and disaster than the doctor, and he always will live in the kind recollections and memory and thought of all who have witnessed his patient, skilful, and faithful work. Nowhere have I seen doctors when I liked them so well as on the present occasion, when I see them laying aside their abstractions, their dogmas, their views, and joining like any common man in laying the foundations of dyspepsia and liver complaints.

The exaltation of the profession is sometimes unduly exemplified in the old story of the young physician who lost mother and child, but succeeded in saving the old man. And we sometimes bring to mind the description of Voltaire, who depicts the physician as coming to the sick-room to enter into a contest with nature and disease. He lays blindly about him with a club. If he hits disease, the man lives; if he hits nature, the man dies.

But what I am expected to talk about is the government of the United States, and I wish to say that the government is "doing as well as could be expected." You doctors say that air and exercise are what we need. And so the United States of America, in its grand march towards its limitless destiny, draws into its continental lungs the winds from the ocean and the breezes from hill and forest; it exercises its sails on countless seas; it digs in the bowels of the earth; it chops down primeval trees; it scatters life and liberty over its boundless domain. Yet, like the doctors, the nation is always being ruined. Every decade I hear them say that the doctor is ruined, that his occupation is gone. What with pellets and hydropathy and clairvoyance he has always felt in danger, and now Christian Science threatens to wrap him in celestial oblivion. But the doctor still lives; and so the government of the United States, always being ruined by the party in power, still lives because of the indestructible character of its natural principle, just as patients are sometimes unkindly said to live on account of a firm constitution which defies the doctor.

One thing we laymen do that is worthy of imitation. When we find a good doctor we stick to him. There is a fresh example of it in the telegram from one of the justices of the Supreme Court of this State, which recently summoned his physician from Newton across the water to London. And so it behooves us to stick to good government. The day of party names has, thank God, gone by. What you and I and we all want, is good government, and when we have that the citizen's duty is the uppermost one in the thought of honest men, and to-day, responding for the government of the United States, I know you will not think I am offending your good sense or violating rules of propriety when I say that at no time has the nation been linked to integrity, to honesty, to rugged intelligence

and to a conscientious devotion to duty more than under the present President of the United States.

Mr. Stearns's speech was greeted with hearty applause, and upon its subsidence, Dr. Richardson introduced the next speaker as follows:

For many years it has been our custom to have with us at these anniversary dinners, representatives of the clerical and legal professions. As representative of the former we have with us to-day a gentleman who is somewhat hard to get on these occasions, but, going on the principle, "if at first you don't succeed, try, try again," we finally secured the Rev. Brooke Herford.

MR. HERFORD said that it gave him pleasure to come to greet a profession kindred with his own. They share the same fortune or misfortune in that the public likes to joke at both. The village doctor and clergyman are the butt of three-fourths of the fun unless the place is big enough to have a lawyer too. I will admit the wits may be a little more severe on the medical profession, like the unconscious irony of the Lancashire woman recounting the facts of her son's illness; he "had no doctor—he just deed himself." The worst that is said of the clergyman is that he sends people to sleep. I observe that this joke falls pointless on this assembly, perhaps because few of you ever subject (I mean are ever able to subject) yourselves to the soporific possibilities of Sunday morning in church. We are alike, therefore, in being the object of jokes, but we are allied also by nobler characteristics. No two professions do so much good, unremunerated work as the medical profession and the one I represent. Nobody but a clergyman knows how much good a doctor does and how little he is paid for it. When I was engaged in my work in a Yorkshire village, I learned to appreciate the noble charity and kindness of the medical profession, and when later my lot came to be cast in great cities I found that amongst the noblest workers for the public good were the members of the same calling. And then no other occupation than ours gives us so much of the love, respect, and honor of our fellow-men. I have always been touched by the tenderness of my own reception in my parish, and the same warmth of feeling awaits the doctor. I can remember the doctor from my earliest years, though I don't pretend to remember as much as my friend Mr. Stearns. I don't remember, like him, when I was born, and I will wager he doesn't remember when he was born again. There may not be quite the close attachment of physician that he remembered in his youth, in these days of many family physicians, when the man has one, the wife another, and the daughter fancies a third. But the physician has reason to rejoice in his calling, hard though it is. And such a gathering as this cheers one. One feels that he belongs to a bigger kind of thing when he is lifted up by the power of numbers.

The next speaker was introduced as follows: A tinge of sadness must of necessity be connected with all annual reunions, for, as the years go by, and we reassemble around the tables at these anniversaries, one and another familiar face is missed. I am not old enough to remember personally many of the veteran leaders whose names we speak of with pride—the Jacksons, Warrens, Ware, and a host of others, but one of the most pleasant remembrances of my student days were the weekly visits at the Massachusetts General Hospital, where I was house-physician, of Dr.

Edward Reynolds, whose genial, courtly, kindly manner to us house-students I can never forget. I take pleasure in introducing one possessing the same characteristics, Dr. John P. Reynolds.

DR. REYNOLDS, in reply, paid a high and deserved compliment to the president of the Society, Dr. Gage, and to the chairman of the occasion, Dr. Richardson; and in closing suggested the hope that the Massachusetts Medical Society might be like the type of one page of Wilberforce's book, growing bigger and bigger, but that the speeches might be like the type of the succeeding page, growing smaller and smaller.

DR. RICHARDSON called next upon Col. Higginson, as follows: For several years the meetings of the council and our annual meetings have been the scene of lively debate on the question of the admission of women to the Society. Both sides fought well, and I take great pleasure, Your Excellency, in saying) neither side employed a lobby. The question was debated on its merits, and, after many defeats, the side claiming to represent woman's rights triumphed, and the doors of the Society were thrown open. From that moment those of us who were beaten fell gracefully into line, and every applicant for admission to the Society has received equal treatment. At our dinner all are equally welcome, and the cigars (which some of us were afraid of offering) are passed to male and female alike, without discrimination. We have with us to-day a gentleman always ready to fight for a good cause. For many years he has battled for so-called woman's rights, whenever he saw a chance, and always with the same fidelity and zeal with which he fought on the battle-fields of the late civil war at the head of his colored troops (the first colored troops, if I remember rightly, ever mastered into the United States service), Col. T. W. Higginson.

COL. HIGGINSON began by referring to the recent dinner of the Ancient and Honorable Artillery Company, where he was called upon to respond to a toast in the capacity of a judge. On his protesting that he was unfit to respond, not being a judge, he was told that if he was not a judge he ought to be. And I suppose you present me to-day, Mr. Chairman, he continued, on the ground that if I am not a woman I ought to be. In the name of our sex I thank you. I see there are six of us besides myself. In the lines of Wordsworth, "we are seven." I was afraid there would be no one but myself,—a constituent without a constituency. So I was glad to see a few cheering bonnets in the procession, though at the rear. Not that the women are reluctant to come, but there is an instinctive sense of propriety about it. Hygeia was a woman and was always young, and therefore the women march near the youngest men of the faculty, as they never grow old. It used to be said that every man of forty was a fool or a physician. The presence here of so many men of mature age accounts for the proverb, and also for the absence of fools. Women were left to be both at once, but, having once let us come in here, you may expect us every year. We will stand by you, we "will never desert Micawber." We will readily come to your assistance, and, when you are at your wit's end, we will endeavor to conceal that we know even less than you do. We have not sought admission to your ranks because we desire an unwarranted enlargement of duty, but that we might share with you in service to mankind. Hippocrates says that the second best remedy is better than the best if

the patient likes it best. So with the second best physician. Whether we turn out second best or not, we must leave to the future to show; and as for the liking of the patient, we are willing to take our chances. What our families are to do in our professional absence, this afternoon may suggest. We shall leave them as you have left your patients to-day, to the mercy of Providence or of some handy young man. Massachusetts has tried to get along all day with nine hundred of her best physicians eating dinner in a skating-rink. When you get home just note how well your patients have fared. But we are glad to accept your invitation to come in with you, which, in justice and comprehensiveness, rivals the notice of a political caucus, to which "all women, without distinction of sex, were welcomed."

The next speaker was presented in these words: As a representative of the legal profession, we turn to one with whose name you are familiar, the Assistant Attorney-General of the State, Col. Harvey N. Shepard.

COL. SHEPARD spoke in general terms commendatory of the law, and felt sure that in the vast majority of cases that came into our courts substantial justice was done. And here our two callings come close together. The courts need advice, expert advice, but there is certainly considerable occasion for reproach in the present aspect of expert testimony. There must, of course, be disagreement in matters of opinion, but there is no reason for such diametrically conflicting statements as those of experts on the witness stand. I do not know the remedy, whether it lies in the appointment of experts by the court or not, but I am sure that something could be done to give to profound learning and sincere conviction due weight.

The next speaker was Mr. Roger Wolcott, whom the chairman presented as follows: The Fellows of this Society have always been ready to help any efforts made to advance medical education or to relieve the sick and wounded. Nothing has done more to further these two objects in Massachusetts than the great hospitals and dispensaries of our large cities. We have with us to-day one of the trustees of the Massachusetts General Hospital, a gentleman who has also made himself well known to us by the admirable service which he has rendered the profession as well as the State as a legislator and member of the celebrated Tewksbury investigating committee, Roger Wolcott.

MR. WOLCOTT said that as a trustee of the Hospital, he experienced a satisfaction with its noble work, a sense of responsibility in the management of so large an institution, and a pleasing excitement in steering so intelligent and wise a staff. There had been an evident advance since two hundred and fifty years ago, when barbers were forbidden to do any surgery but pull teeth, and surgeons were forbidden to do shaving.

The demands of modern surgery are felt by every trustee of the Hospital, and a new ward is to be built for abdominal surgery. The student of these days has passed far beyond mere empirical knowledge. He must pursue scientific investigation, and to this end scholarships ought to be more plenty. There is in Harvard College an average of but one scholarship to one hundred students. In the Medical School there are two hundred and seventy-one students, and but six scholarships. What better could a man do than found more scholarships here? "And yet," as the minister prayed, "we would not dietate, but venture to advise, O Lord." It is not credible that we have

so few scholarships in the Medical School. Times have changed, since, in 1836, Mason Warren wrote home from Paris of the enmities and jealousies among the professional men there. That is past, and the profession to-day is full of promise. Who shall doubt, that, as the camera traces the outlines and the constitutions of hitherto undiscovered stars, the trained and educated intellect may reveal facts and conjectures and truths that no eye can now discern? The Massachusetts General Hospital commands the services of the most eminent professors of your art, services, now as ever, not devoid of danger. One after another has given up his life in the service. What was said of one not long deceased,—“a noble life given to preserve an ignoble one,”—may be said of many another physician, all of whom willingly carry their lives in their hands for the sake of suffering humanity.

The Chairman then called upon the last speaker of the day in these words: If we are to credit one-half of the marvellous stories which the gypsies tell, and the ignorant and sceptical believe, it would seem as though the work of our profession were at an end. A new class of practitioners have arisen, and are rapidly permeating those who run after every absurd theory, such as that, there being no body, there can be no disease. We know what humbug all this so-called mind-cure is, but, as intelligent physicians, we recognize that the mind does influence the body, though we do not pretend as yet to absolutely define the relationship. It is with pleasure that I introduce to you a gentleman who has recently come from England to assume the secretaryship of the American Society for Psychical Research—a society which is doing good service in trying to study out this problem of the mind—Mr. Richard Hodgson.

MR. HODGSON, after a humorous reference to the possible uncertainty of knowing who is who, if the capacity of mental influence upon others were to become universal, said that he believed that the fact of the influence of mental states upon organic functions was daily becoming of more importance. To investigate such matters, the Society for Psychical Research had been started. Facts once scouted were now established and looked upon as ordinary phenomena. He cited a number of illustrative cases, which showed, he said, that hypnotism and kindred subjects deserved the study of trained medical men. For such study, America ought to be a fertile field—the scene of such fusion and confusion of ancestral races and habits.

With this closed the exercises of the annual meeting, which was voted by all present to have been of unusual interest and enjoyment.

#### AMERICAN CLIMATOLOGICAL ASSOCIATION.<sup>1</sup> FOURTH ANNUAL MEETING.

##### THE LOCAL TREATMENT OF DISEASES OF THE RESPIRATORY ORGANS,

by DR. B. F. WESTBROOK, of Brooklyn.

The methods of treatment which had been employed were the direct introduction of coarse sprays, the use of the Evans inhaler, and the use of the pneumatic cabinet. In cases of chronic bronchitis, where the cough was severe, a spray of a solution of carbolic acid fluid extract of hyoscyamus or other sedative

remedies was employed. Where there is copious secretion, astringents are called for, and of these, tannic acid, iron, salts, and fluid extract of pinus canadensis had been employed. The pneumatic cabinet had been used with marked success in the treatment of chronic bronchitis. The patient is confined in the cabinet under a diminished pressure, the sitting lasting from ten to fifteen minutes. This may be combined with the inhalation of the spray. If there is much emphysema, the cabinet is not indicated. In using the cabinet in the treatment of chronic interstitial pneumonia and bronchiectasis, there is danger, if the pressure is great, of producing emphysema of those portions of the lung still accessible to the air. The pressure should not exceed one-half-an-inch of mercury.

In the treatment of phthisis, the best results are obtained in the early stages of the disease, or where the disease, although further advanced, is limited to a smaller portion of the lung. The use of sprays is beneficial in only so far as we desire to treat the co-existent bronchitis, or cavities connected with bronchi of the second or third order. In incipient phthisis, with very little bronchial catarrh, local treatment is probably of little service. These cases are best treated with compressed air. In a large proportion of the cases, we may hope to render the disease latent. The expansion of the lung favors the expectoration of the contents of the smaller tubes, and modifies the intrathoracic circulation. The sittings should be frequent—every day, or every second day. Ten minutes is usually sufficiently long for the patient to remain in the cabinet. The pressure should gradually be increased up to one-half to three-quarters of an inch. If used cautiously, this is the best method for the local treatment of incipient phthisis. With the Evans inhaler, his results had also been satisfactory.

In the treatment of advanced cases of phthisis, the first effort must be to cure or diminish the bronchitis. The pneumatic treatment then comes into play. This gives better expansion, improves the circulation, and alters the action of the trophic nerves. In all cases, internal medication has been combined with the local treatment. The more acute the disease, the higher the fever; and the more sudden the onset, the less can we expect to accomplish by treatment. In no case diagnosed as acute phthisis did treatment have the slightest effect.

THURSDAY.

The first paper of the morning session was entitled:

##### OBSERVATIONS UPON THE SANITARY ADVANTAGES OF TIDE WATER, VA., INCLUDING VIRGINIA BEACH AS A WINTER HEALTH RESORT,

by DR. A. Y. P. GARNETT, of Washington, D. C.

While no official records of the causes of death in this locality have been kept, the traditions of the inhabitants during the past hundred years and the observation of intelligent practitioners practising in this region, go to show that consumption is very rare. In other respects this locality is remarkably healthy. The average number of deaths per thousand from all causes during the past six years has been 10.66. The average death-rate in other sections of the State is 12 per thousand. The author was disposed to attribute some of the benefits which this locality presents, to the proximity of the Great Dismal Swamp, which has an area of thirty by ten miles, covered with cypress and evergreen trees. At Virginia Beach the forest

<sup>1</sup> Concluded from page 581.

comes down close to the sea. The atmosphere is remarkably dry and salt, exposed during the day shows no tendency to absorb moisture. The average temperature during the winter months is considerably higher than at other places along the coast. As compared with Atlantic City, we have the following figures:

	Virginia Beach.	Atlantic City.
January . . . . .	34.6°	30°
February . . . . .	39°	39°
March . . . . .	45°	38.2°

The average humidity is also much less than it is at Atlantic City.

## DISCUSSION.

DR. WALTER PLATT, of Baltimore. With reference to the rate of mortality given in the paper, I would state that I think that very little reliance is to be put in the statistics of sparsely-settled districts. It is extremely difficult in these sections to get the citizens to make a proper report of the deaths to the authorities.

## EVERGREEN FORESTS AS A THERAPEUTIC AGENT IN PULMONARY PHTHISIS.

by A. L. LOOMIS, M.D., of New York.

It has long been known that similar climates as determined by geographical and meteorological conditions have different therapeutic effects. That there is some relation between the development of organisms and atmospheric conditions is becoming more and more apparent. We know that cold and high altitudes render the air aseptic, but the degree of cold and the height required is so great that clinically it is not possible to derive much advantage from this fact. The effect of a purely aseptic air upon ulcerative processes is not so great as the effect of an atmosphere which is aseptic on account of the presence of antiseptic agents. The belief in the good effect of pine forests in cases of phthisis is quite unanimous, and the author thought that the clinical evidence in favor of their beneficial influence in these cases was unquestioned. The atmosphere in such regions is not only aseptic, but also antiseptic. Such an atmosphere contains considerable turpentine vapor, and we should therefore expect it to contain a certain amount of peroxide of hydrogen. It was the speaker's opinion that the majority of cases of phthisis die not directly from the lesions in the lung, but from the secondary septicæmia and pyæmia which is set up. It is impossible to apply to the ulcerations within the lung the antiseptic washing and dressing that is employed in external lesions, but if an antiseptic atmosphere can be obtained we may hope to counteract the secondary poisoning. Such an atmosphere will not destroy the bacilli, but it will accomplish much in the way of arresting the suppurative process. It was the opinion of the speaker that the atmosphere in the region of evergreen forests acts in a manner similar to the antiseptic agents which are successfully used to arrest suppurative processes in other portions of the body, and he thought that in all probability the active agent was the peroxide of hydrogen resulting from the oxidation of the turpentine vapor. While it is not possible for every one suffering with pulmonary phthisis to go to an antiseptic atmosphere, yet it is possible to render the air of any particular locality antiseptic. The evergreen forests should be preserved, and evergreen trees should be planted in the neighborhood of our homes.

## DISCUSSION.

DR. S. S. COHEN, of Philadelphia. The paper tends to confirm certain impressions which I have formed from an experience with certain methods of making an artificial climate. I have had excellent results in the way of alleviation of symptoms in phthisis by the inhalation of terebinthinate substances, especially where this has been associated with the inhalation of peroxide of hydrogen or oxygen. Under these inhalations I have seen laryngeal ulcers cicatrice, especially if they have been previously washed with the solution of peroxide of hydrogen.

The paper was further discussed by DRs. BRUEN, WESTBROOK, GARNETT, and MUSSER.

## THE CLIMATE OF THE SUB-PENINSULA PINELLAS, FLORIDA.

by DR. W. C. VAN BIBBER, of Baltimore.

## ENVIRONMENT IN ITS RELATION TO THE PROGRESS OF BACTERIAL INVASION OF TUBERCULOSIS.

by DR. E. L. TRUDEAU, of Sarnac Lake.

Environment evidently has an important bearing in reference to bacterial invasion. The author proposed to himself the following questions: (1) What results ensue when bacillar invasion and unhygienic conditions are made to co-exist? (2) Are unhygienic surroundings sufficient to cause phthisis when precautions are taken to exclude the bacillus? (3) Is bacterial infection always productive of tuberculosis when the animal is placed under the most favorable hygienic conditions? In order to answer these questions the following experiments were performed: Fifteen healthy rabbits were taken and divided into three sets of five each. The first experiment consisted in taking five of the rabbits, inoculating each with a pure culture of the tubercle bacillus and subjecting them to overcrowding in a dark cellar, with poor and insufficient food and other unhygienic conditions. In the second experiment, five rabbits were placed in a box and lowered into a pit dug in the ground, the mouth of the pit covered with earth with the exception of a trap-door for the introduction of food, which consisted of one small potato for each animal per day. So damp was the air that the box in which the animals were confined was constantly wet. The third set of animals were inoculated with the tubercle bacillus and turned loose on a small island, where they had abundant sunlight, fresh air and exercise. They were daily supplied with wholesome food.

The results of these experiments were that four of the first five rabbits died in three months, and extensive tuberculosis found. The fifth animal was killed at the end of five months and the same condition found. The second set of five rabbits were all living at the end of four months. They seemed to be as active as at the time the experiment began. They were then killed and careful examination revealed nothing abnormal. One of the third series of rabbits died at the end of one month, and on examination there was enlargement of the cervical and bronchial glands and tubercles in the spleen. The remaining rabbits continued in apparently good health, and were killed at the end of four months. They were loaded with adipose tissue, the flesh was firm and red, all the organs were normal, and even the seat of the punctures could not be made out. These experiments confirm the

view that the production of tuberculosis is a most complex process. Although the environment may bear out the relation of a predisposing cause to the microbe invasion, it is nevertheless a most potent factor in determining the future and the final results of the disease, and while we may not underestimate the pathogenic properties of the bacillus, the effect of environment upon the vitality is a factor which must not be ignored.

#### AFTERNOON SESSION.

The first paper was read by DR. WALTER PLATT, of Baltimore, on the

CLIMATE OF ST. MORITZ, UPPER ENGADINE, SWITZERLAND.

DR. A. C. PEALE, of the United States Geological Survey, Washington, presented

A CLASSIFICATION OF AMERICAN MINERAL WATERS.

ST. AUGUSTINE AS A WINTER HEALTH RESORT, was the title of a paper by DR. F. F. SMITH, of St. Augustine.

He described the geographical and climatic conditions existing in St. Augustine. An abundance of pure water is obtained from sixty artesian wells. This water is charged with sulphuretted hydrogen. Drinking-water is obtained by means of cisterns. A complete system of sewers is now being introduced. These will be flushed by the waste water from the artesian wells. The average temperature during the winter months of the past ten years has been as follows: November 63°, December 57°, January 55°, February 58°, March 61°, and April 67°. The average number of rainy days during the winter months for the past ten years has been 33, but on 19 of these occasions the rainfall was at night, so that there was really only 14 rainy days.

The following papers were read by title:

AN INVALID'S DAY IN COLORADO SPRINGS, by DR. S. E. SOLLY, of Colorado Springs.

THE CLIMATE OF SOUTHERN CALIFORNIA, by DR. H. S. ORMS, of Los Angeles, Cal.

PAS CHRISTIAN, MISSISSIPPI, AS A HEALTH RESORT, by DR. CHARLES LE ROUX, of Pas Christian.

The report of the Committee on the Congress of American Physicians and Surgeons was received and adopted. Dr. A. L. Loomis, of New York (with Dr. F. Donaldson, Sr., of Baltimore, as alternate), was appointed as the representative of the Association to the Committee on the Congress.

The following were elected to membership: Drs. A. L. Gilson, U. S. N.; W. D. McDougal, San José; A. C. Peale, U. S. Geological Survey; E. Wilos Linn, Los Angeles; F. F. Smith, St. Augustine; F. P. Henry, J. J. Yerick, and Thos. J. Mays, Philadelphia; Thos. C. Leatmer, J. Carey Thomas, and Walter Platt, of Baltimore; S. E. Solly, Colorado; S. W. Langmaid, Boston; S. E. Morgan, Washington; S. H. Chapman, New Haven; and S. A. Fisk, Denver.

#### OFFICERS FOR THE ENSUING YEAR.

President, Dr. A. L. Loomis, New York. Vice-President, Dr. A. Y. P. Garnett, Washington, and James T. Whittaker, Cincinnati. Secretary and Treas-

urer, Dr. James B. Walker, Philadelphia. Council, Drs. E. T. Bruen, Philadelphia; J. H. Tyndale, New York; F. H. Bosworth, New York; F. C. Shattuck, Boston; and R. G. Curtin, Philadelphia.

The Association then adjourned.

#### ASSOCIATION OF AMERICAN PHYSICIANS.<sup>1</sup>

##### SECOND ANNUAL MEETING.

##### CASES OF SEWER-GAS POISONING.

by DR. HENRY HUN, of Albany.

The author reported in detail the histories of twenty-nine cases coming under his observation, in which various diseases appeared to have been due to the inhalation of sewer-gas. He thought it probable that the following diseases may result from sewer-gas poisoning: vomiting and purging, separately or combined; general debility, fever, sore throat of a diphtheritic type, neuralgia, and perhaps, also, myelitis of the anterior horns. These conditions are frequently combined. Fever is frequently associated with the other symptoms. There is one group of symptoms which is almost always present; that is, loss of appetite, extreme prostration, and pain in the head. When this occurs as a chronic condition, we are justified in suspecting that the patient is suffering from sewer-gas poisoning.

##### DISCUSSION.

DR. A. W. JOHNSTON, of Washington. The theory of sewer-gas poisoning has gradually taken the place of malaria as the supposed cause of many obscure conditions, just as malaria superseded the liver origin of disease. The theory which attributes many of these conditions to the presence of sewer-gas has not been proven. In an examination of a number of men working in the sewers of this city, it was found that they were more healthy than those who worked above ground, and the same observation has been made in other places.

A CASE OF ANEURISM OF THE ABDOMINAL AORTA,<sup>2</sup>

by DR. ISRAEL T. DANA, of Portland, Me.

##### EVENING SESSION.

##### DISCUSSION. — HÆMORRHAGIC INFARCTION.

Opened by DR. W. W. WELCH, of Baltimore, referee.

The author first referred to the different theories which had been advanced to explain the occurrence of hemorrhagic infarctions. These are: (1) Changes in the wall of the artery obstructed. (2) The increased pressure with which the blood is sent in from the collateral circulation. (3) A regurgitant flow of blood from the veins. Numerous experiments had been performed by the author, with the assistance of Dr. Mall, of Johns Hopkins University, to determine which of these theories was the correct one. Hemorrhagic infarctions were produced in the intestines of dogs, and the method of experimentation was given in detail. He presented, as the result of his studies, the following conclusions:

(1) The blood which produces hemorrhagic infarctions comes chiefly, if not exclusively, from the collateral vessels.

(2) Hemorrhagic infarctions in the intestine can-

<sup>1</sup> Continued from page 586.

<sup>2</sup> See page 573, No. 24 of the Journal.

not take place merely from the reflux of blood from the veins.

(3) The blood-pressure is very low in the region where hemorrhagic infarction occurs, in consequence of occlusion of the main artery.

(4) A certain degree of force of the collateral circulation is required to produce a hemorrhagic infarction.

(5) No positive proof exists that a change in the vascular walls is essential to the production of a hemorrhagic infarction.

(6) The hemorrhage occurs by diapedesis.

(7) Where hemorrhagic infarction has taken place, the large and small veins are widely dilated with blood, and the arteries contain a smaller quantity of blood than normal. There is stasis in many of the veins and capillaries.

DR. WILLIAM OSLER, of Philadelphia, the conferee, referred to the

#### CLINICAL ASPECTS OF THE SUBJECT.

Among other cases coming under his observation, he reported the following: J. M., aged twenty, admitted to the Philadelphia Hospital October 10, 1886. He had never had syphilis, and was a healthy-looking man. He presented a clear history of typhoid fever, with a sickness of six weeks, two years previously. His present illness began with diarrhoea, one week before admission. For two days he had attacks of bleeding at the nose. There was temperature of 102°, with pain in the abdomen. There was no cardiac murmur, and examination of the lungs gave negative results. The splenic dulness was increased. By October 15th the temperature had reached 103°. There was almost constant delirium. There was some diarrhoea. Coldness of the feet appeared, and continued to increase in degree, and extended up the leg. The legs became livid, and no pulsation could be detected in the femoral and popliteal vessels. The patient died on the 17th. It was supposed that there was thrombosis of the iliac veins, with gangrene of the legs, which is one of the rare sequences of typhoid fever. At the autopsy, it was found that the lower portion of the abdominal aorta, and also the two iliac arteries, were plugged with thrombi. There was general peritonitis. The right kidney presented a red-brown infarction. There were no ulcerations in the bowels; no endocarditis. The lungs were normal. There was an infarction in the spleen. During life the blood was examined for microbes, but none were found. After death, microbes were found in the spleen.

Hemorrhagic infarction of the liver, under ordinary circumstances, is impossible. A. B., a hard drinker, was admitted to the hospital September 27th. His illness began, in the previous June, with vomiting and swelling of the abdomen. The dropsy steadily increased. He died two days after admission. At the autopsy, a large amount of fluid was found in the peritoneal cavity. There was nothing special found in the heart or lungs. The liver was remarkably cirrhotic. Through the right half of the right lobe, there were scattered numerous reddish-brown areas. The walls of the portal vein were thickened, and a large brown thrombus occupied the upper portion of its trunk. The branches passing to the right lobe were filled with clots. The hepatic artery and vein were normal. In this case, the hemorrhagic infarctions were in all probability due to the cirrhosis of the liver, which had caused more or less obstruction of the

branches of the hepatic artery. The only other case of infarction of the liver which the speaker had been able to find, was one reported by Recklinghausen.

In the intestine, hemorrhagic infarctions are met with in two forms: one involving the mucosa, the other affecting the entire gut. The former not infrequently ends in ulcerative necrosis. The latter form of hemorrhagic infarction is not common in man. In the horse it is frequently seen, resulting from thrombi formed from verminous aneurisms of the mesenteric and its branches. This is a common cause of the severe and fatal colic so frequently seen in these animals. In conclusion, the speaker referred to the fact that, in the lung, it was not uncommon to have a vessel blocked without the production of an infarction. An occasional cause of thrombotic infarction is local disease of the pulmonary artery. It sometimes results from the endarteritis induced by beginning tubercular processes.

#### DISCUSSION.

DR. REGINALD H. FITZ, of Boston. I should like to report a case which, in my experience, is quite unique. It was that of an elderly man with globular thrombi in the left ventricle. Emboli were transferred to the splenic artery, but at first were not sufficient to completely occlude the artery. The spleen became enlarged and thrombi formed in the splenic veins and from this point the thrombus extended into the superior mesenteric vein. As a consequence, hemorrhagic infarction occurred in the intestine.

#### FRIDAY.—SECOND DAY.—MORNING SESSION.

##### BERGEON'S METHOD OF TREATING PHTHISIS.

by DR. E. T. BRUEN, of Philadelphia.

With reference to the effect of the injections of sulphuretted hydrogen on the bacillus tuberculosis, Bergeon does not claim that their number has been reduced in any considerable proportion of cases. In the treatment of phthisis there are three main indications. The first is to secure some agent which will act upon the cause of the disease. Climate, diet, and hygiene serve to modify the predisposing causes, but if the bacillus be the real cause of the disease, we lack any agent which will destroy it. The second indication is to prevent the destruction of the tissues, for it is found that as the vitality is increased the number of organisms in the sputa is diminished. The third indication is to control special symptoms which present themselves. Since February last, I have employed Bergeon's method of treatment in sixty-one cases. Forty-four of these cases have been benefited, but of these only three appeared to regain full health. Two of these were cases of incipient phthisis with apparent consolidation of the apex of the right lung. In one of these cases the bacillus tuberculosis was not found, although five examinations were made. In the other case the bacillus was found. In these cases the apparent recovery has been associated with a decided increase in weight. I believe, however, that the disease is simply latent. The third case was one of broncho-pneumonia. In all the other cases the lesions were more or less advanced with the presence of cavities and profuse expectoration. In the fifteen cases in which a negative result was obtained, the treatment in some was followed by temporary benefit. The good results have consisted in lessening of the expectoration, diminution of the cough, lowering of the temper-

ature, and suspending of the night sweats. In most of the cases there was a diminution of from fifteen to twenty beats in the pulse, and a diminution of half a degree in the temperature, during the administration of the gas. Even in those cases which were benefited, and in which the temperature had been brought to normal, there would be during the progress of the treatment, occasional outbreaks with a return of the fever and the other symptoms. These, however, disappeared under a continuance of the injections. In order to determine the effect of the treatment on the bacillus, Dr. E. O. Shakespeare made a number of examinations during the progress of the cases. There has been no diminution in the number of the bacilli. It was, however, thought that in those cases where the treatment had been continued for some time, the reaction of the bacilli to the staining fluid was less marked.

Two cases have died. In one of these an autopsy was made. This case had been under treatment for two months. The walls of the cavity were moderately smooth and firm, but there was no tendency to cicatrization. The results were of a decidedly negative character.

In most of the cases a solution made by the addition of five grains each of sodium sulphide and sodium chloride to a pint-and-a-half of water was the solution employed. In some cases the strength of the solution had been gradually increased, but where no benefit had been obtained from the weak solution, the stronger solution did not act with any better results. The quantity of gas employed at each injection has been about one gallon. If there is pain the strength of the solution may be decreased or a smaller quantity of the gas may be given. At least an hour should be consumed in each administration of the gas. The patient should rest quietly in bed an additional half hour until the gas has been absorbed. The admission of atmospheric air should be avoided.

In cases of diarrhoea his experience had been unfavorable except where the gas was given in very small quantities. Chronic peritonitis is a contra-indication to the use of this plan of treatment. In about one case in every ten, he had observed the reaction of sulphuretted hydrogen, when a paper treated with acetate of lead had been applied to the mouth. This would indicate that a very small amount of the gas reaches the lung, and that the efficiency of the treatment does not depend upon the use of a strong solution. In no case has any injurious results been seen. In some cases where strong solutions were employed, the appetite and strength seemed to be impaired.

Bergeon's method is chiefly valuable in those cases attended with bronchial catarrh. He had had very little good effect in those cases where there was thickening of the lung without much catarrh. The speaker feared that the trouble and detail necessary to the successful application of this method and the limitations of its power would cause it to be set aside for other therapeutic measures.

#### CLINICAL NOTES ON BERGEON'S METHOD OF TREATING PHTHISIS,

by F. C. SHATTUCK, M.D., of Boston.

The amount of gas contained in the water recommended by Bergeon is only three cubic centimeters, an extremely small quantity. It seemed to him almost impossible that such a small quantity of sulphuretted

hydrogen could have any appreciable effect. The solution which Dr. Bruen employed probably contained one hundred and fifty cubic centimeters of sulphuretted hydrogen. Bergeon attributes the good effects to the antiseptic influences of the gas on the suppurative processes. Dr. Trudeau has found that cultures of the bacteria of suppuration and of the bacillus of tuberculosis are unaffected by being kept in an atmosphere of sulphurous acid gas. The speaker had treated only seven cases by this method. They were in an advanced stage of the disease. He had seen such improvement follow careful dietetic and hygienic management, that he had not much confidence in the results claimed for special methods of treatment in these cases. Any new method of treatment will often have an apparently beneficial effect through its influence on the mind, even in those cases which are incurable. Six of the cases treated suffered with phthisis, and five were an advanced stage of the disease. One was a case of chronic bronchitis, with asthma and emphysema. Four of the patients suffered with more or less pronounced collapse from the use of the injections. Nausea, vomiting, and diarrhoea occurred in several cases. In one case, although the patient was weak, no local or general ill effect was observed. In another case, the treatment was continued four weeks with no ill effect. The only benefit obtained was a diminution of the expectoration. In the case of asthma and chronic bronchitis, thirty-four enemata were given. The improvement was no more rapid than on a previous occasion, when the patient had been treated in the same general way, with the exception of the gas. He presented the following conclusions:

(1) Toxic symptoms may follow the injection of sulphuretted hydrogen gas. These are nausea, vomiting, general depression, collapse, and perhaps headache.

(2) Strong artificial solutions of sulphuretted hydrogen gas, with carbonic acid gas, are apt to cause abdominal discomfort. The risk of this is diminished by heating the solution of the former gas.

(3) This is not by any means a specific. If useful at all, it is only as an auxiliary to the more usual methods of treatment.

(4) The only benefit which we have seen that could be fairly attributed to the enemata was a diminution in the amount of the expectoration.

In conclusion, the author stated that the impression which he had formed was that the good results which had unquestionably followed this method of treatment were attributable, in large part, to the stimulation induced by the employment of a novel method of treatment, which makes the patient feel that something is being done for him.

#### DISCUSSION.

DR. WILLIAM PEPPER, of Philadelphia. I have, with the assistance of Dr. J. Crozier Griffith, employed this method in a certain number of cases. The injections were given to thirty-four cases; but in ten of them, either on account of the pain induced, or for other reasons, the treatment was discontinued. In the remaining twenty-four cases, the treatment was continued, on an average, twenty-five days. Other treatment was frequently combined with the use of the injections. A daily temperature record was kept in sixteen cases. In four, there was more or less reduction. In eleven, there was no appreciable effect. In one temperature increased, but this was probably a

coincidence. In no case was the temperature brought from a febrile to a continuously normal condition. The fall was not more than is seen in similar cases under other methods of treatment.

In twenty cases in which the weight was recorded there was in eight more or less gain. Eight pounds in thirty-seven days, was the greatest gain. In six cases the weight remained stationary, and in six it was diminished.

The improvement in cough was not marked. The expectoration was somewhat diminished in four out of twenty-four cases. Search was made for the bacilli in thirty cases, and they were found in twenty-seven. In eleven cases the examination was repeated, and only in four was there any apparent decrease. Cases of night sweats were not numerous. In one they were checked and in seven improved. Physical examination showed no improvement in a single case. The enemata had a decided hypnotic influence in three cases. The only unpleasant symptom of any real moment was colic. This was complained of in eleven out of twenty-four cases. Three others suffered so much that the treatment could not be repeated. The colic was not often controlled by giving smaller quantities of the gas, nor did it seem to be influenced by the slowness of the injection. This method of treatment is seldom of real benefit, although it is occasionally of benefit by relieving certain symptoms.

Dr. H. C. Wood, of Philadelphia. After studying the cases treated by this method, I came to the conclusion that it was of a certain amount of benefit. I saw that the method of employing the gas presented many objections. The sulphuretted hydrogen should accomplish the same results when absorbed by the stomach as when taken up by the large intestine. I have therefore administered the sulphuretted hydrogen gas in carbonic acid water. Water at the ordinary temperature takes up two or three times its volume of sulphuretted hydrogen. I think that this is a distinct addition to pulmonary therapeutics. I have tried it in certain cases with benefit. I would call attention to the fact that this is not a new method. In connection with many of the sulphur springs of Europe, there are chambers fitted up where pulmonary catarrh can be treated by inhalation of the gas.

Dr. BEVERLY ROBINSON, of New York. I have employed this method for the past two months, and my impression is that it is a valuable adjunct to our methods of treatment. The pain which is experienced in many cases may be due to the fact that there are ulcerations in the intestine. These may be present without the existence of diarrhoea. I have under treatment a case in which tubercular deposits in the lungs is associated with ulceration of the larynx. I thought that this would be a good case to observe the influence of the gas on the local condition. The man has received a daily injection for the past ten days. There has not been the slightest change in the appearance of the larynx.

Dr. GEORGE L. PEABODY, of New York. I have followed all the details of this method of treatment as given by Bergeon and have used the water of Aubon which he recommends. My results have not been materially better than those of the gentlemen who have preceded me.

Dr. F. FORSHEIMER, of Cincinnati. I have treated thirteen cases with this method. I have performed the following experiments. I have treated two or

three patients in the way recommended, for some time. Then I have substituted for the sulphur solution plain water, and continued the injections for a time. I have also given the carbonic acid gas by injection, and lastly, I have for two weeks treated these cases with the injection of air, using the Bergeon apparatus. The patients in these experiments of course did not know that any change had been made in the gas employed. As far as I have been able to judge, the patients treated with air did about as well as those treated with sulphuretted hydrogen. It is clear to me that the introduction of air is not the cause of the pain in the Bergeon method.

Dr. JAMES T. WHITTAKER, of Cincinnati. I have used the sulphuretted hydrogen gas both by injection and also by inhalation. The effects under both methods of administration seem to be the same. It mitigates the cough, relieves the fever, and lessens the night sweats. It however is not a specific.

(To be continued.)

#### THE AMERICAN LARYNGOLOGICAL ASSOCIATION.<sup>1</sup>

NINTH ANNUAL CONGRESS.

Dr. C. C. RICE, of New York, read a paper entitled

GLANDULAR AND CONNECTIVE-TISSUE HYPERTROPHIES IN THE LATERAL WALLS OF THE PHARYNX,

The next paper was on

THE GALVANO-CAUTERY IN THE TREATMENT OF HYPERTROPHIED TONSILS,

by Dr. CHARLES H. KNIGHT, of New York.

The speaker first referred to the objections to the cutting operation. The principal of these is the danger of hæmorrhage. At times, the tonsil is so deeply situated that it is not possible to get the tonsil-tome over it. In other cases, the patients positively object to the cutting operation. There are two methods of using the galvano-cautery: one is by puncture, and the other by the snare. The former is much the slower. Not more than three punctures should be made at each sitting. The number of sittings required vary from five to ten. The latter method with the snare is much the quicker. The current should be used intermittently, and contraction should only be made during the passage of the current. He did not recommend this as a universal operation. In the majority of cases, the cutting operation is easier and better. It should be used where there was danger of hæmorrhage, and he was almost disposed to say that the galvano-cautery should be used in all cases in adults.

#### DISCUSSION.

Dr. C. E. SAJOURS, of Philadelphia. I have tried galvano-puncture, but it is quite tedious. I have modified the method by making a puncture, and then introducing chromic acid. I think that the use of the snare is an excellent method.

Dr. A. W. MACCOW, of Philadelphia. In the treatment of these cases, I make a distinction in the methods employed. In the glandular enlargements I have used puncture, while in the interstitial hypertrophies I have not used it, for in these cases you are apt to get cicatrices, which give considerable trouble. I

<sup>1</sup> Continued from page 589.

am not satisfied that the puncture is any better than chromic acid fused on a probe and passed into a crypt.

DR. BEVERLY ROBINSON, of New York. I have long held that we know of no simple operation in surgery. There is nothing that is so unpleasant to me as to remove large tonsils from a small child. Although, as a rule, the hæmorrhage is readily controlled, yet I always undertake the operation with a good deal of reluctance. I am disposed to think that galvanocautery is one of the best methods. We can thus remove many tonsils that give us a good deal of apprehension.

DR. C. C. RICE, of New York. Very little can be accomplished with the cautery in the large white hypertrophies in children. The cutting operation is what must be done in these cases. In adults, however, galvanocautery is the most useful measure.

The President, DR. E. FLETCHER INGALLS, of Chicago. I have used the cautery, but a certain amount of soreness has always followed its use. In children, in order to avoid the pain and nervous shock attending the cutting operation, I am in the habit of etherizing the patient and removing the tonsil with the snare.

DR. HARRISON ALLEN, of Philadelphia. While it may be proper to do the cutting operation in certain cases of hypertrophied tonsils which have been selected with great care, I think that we err in making broad statements in regard to this operation. I believe that the number of cases in which serious hæmorrhage occurs is much larger than is supposed. All the disastrous cases are not reported. I am not willing to perform the operation until I have studied the case very carefully. Other measures should be first used, and the knife resorted to at the last.

DR. D. BRYSON DELAVAN, of New York. Where the operation of tonsilotomy is done with proper care and with proper styptics at hand, I think there is not much danger from hæmorrhage. At first there is a gush of blood, but in a few seconds this stops. I have found it very difficult to get authentic reports of cases in which serious hæmorrhage followed this operation.

DR. MORRIS J. ASCH, of New York. With reference to this question of hæmorrhage, I would state that some time ago one of my assistants removed a small section of the tonsil. The next day there was serious bleeding, and it was found necessary to keep up pressure on the tonsil for six hours before it was controlled. In another case that I know of, it was found necessary to tie the common carotid artery.

DR. J. SOLIS COHEN, of Philadelphia. I think that a great deal of the trouble in tonsilotomy is due to the adhesion of the anterior fold of the palate to the tonsil. It has been my custom to first free the tonsil from the palate. In many cases, the tonsil will then go down without any treatment whatever. I think that the hæmorrhage comes from the cutting of this fold, for, as the vessels run in a vertical direction, they are cut obliquely. I have never been able to use the cautery with the success of the reader of the paper. In my cases, it has required from twenty to fifty sittings. One plan that I have followed is, after having penetrated the tonsil transversely, to try to cut my way out, then to cut in the other way, and thus remove a portion of the tonsil. In this way, by making the application every day or every other day, the tonsil is removed in the course of a month or six weeks.

#### NOTE ON A FREQUENT CAUSE OF NASAL HÆMORRHAGE,

by DR. BEVERLY ROBINSON, of New York.

In the experience of the author, the ulcerations in atrophic rhinitis had been a most frequent cause of hæmorrhage. He had found himself unable to detach the crusts from these ulcerations, either by the use of douches or sprays, so well as by the employment of ointments. In the course of two or three days, the patient is able to blow out the crusts. He had found no ointment act so well in imbibing the crusts and producing changes in the ulcerations as the ammoniated mercury ointment of the Pharmacopœia, of one-half or full strength, made up with vaseline. In applying plugs in the case of hæmorrhage, he had found nothing so useful, especially in children, as Steele's flexible probe, recommended by Dr. J. Solis Cohen. He had found the so-called sheet-sponge very useful as a plug. This may be cut in long strips, and pushed through the nose until the bleeding is controlled.

#### SATURDAY, THIRD DAY. — MORNING SESSION.

##### CONSTITUTIONAL CAUSES OF THROAT AFFECTIONS,

by S. W. LANGMAID, M.D., of Boston.

He suggested that the most interesting lesson to be drawn from the observation of the lesions in throat trouble is that there is some underlying cause, which may be external or intrinsic. Our attention has been directed too much to the local condition and to atmospheric influences. Why atmospheric conditions are active at one time, and not at another, is a matter worthy of consideration. One of the most intractable diseases which we have to treat is chronic recurring coryza. Sometimes destruction of the mucous membrane of the nose is sufficient, but, as a rule, the treatment must take in all the circumstances of the life of the sufferer. A sense of a lump in the throat, so often complained of, is often an indication of an overloaded colon, and more good is done by a dose of castor oil than by local treatment. The so-called clergyman's sore throat, or follicular laryngitis, has its origin not in the necessary use of the throat, but the sedentary life, with errors in diet and other conditions, play an important part. Throat trouble is sometimes a rheumatic or gouty manifestation, and treatment has to be directed to this condition. Local treatment, in many throat troubles, is of the nature of repair; constitutional and hygienic treatment must be in the direction of a renewal of the normal processes. Swelling and congestion of the mucous membrane, hypertrophy of the tonsil, elongation of the uvula, etc., must be regarded as symptoms, and the symptoms will not be banished unless the underlying constitutional abnormality be removed.

#### DISCUSSION.

DR. W. C. GLASGOW, of St. Louis. I agree with the author that many of these local conditions are symptomatic. Many of them are due to some derangement of the digestive apparatus.

DR. J. SOLIS COHEN, of Philadelphia. This is an important paper. With reference to rheumatic sore throat, I have had doubts as to the correctness of this term. I have found symptoms closely like those of this affection follow the application of the galvanocautery to the pharynx and tonsils. Patients often suffer pain in the trapezius muscle from an application of the cautery to the tonsil. I have found the use of

guaiac as serviceable here as where the trouble is due to exposure to cold. Whether this is nervous or not, I cannot say. I treat my patients constitutionally, using purgatives two or three times a week. There is one form of pharyngitis in adolescents which I have considered to be due to over-feeding.

DR. D. BRYSON DELAVAN, of New York. In this country, we pay too little attention to the hygienic surroundings which are employed at the various spas abroad. The method of treatment is very beneficial in cases of interference with the portal circulation, and in gouty diathesis. I have found the salicylates of great service in some of these cases of throat trouble. Habitual constipation usually accompanies chronic diseases of the pharynx. I have used, in these cases, the official pill of iron and aloes, directing that one be taken at night.

The following papers were read by title:

AFFECTIONS OF THE CRICO-ARTENOID ARTICULATION,  
by GEORGE W. MAJOR, M.D., of Montréal.

CANCER OF THE LARYNX,

by HOSMER A. JOHNSON, M.D., of Chicago.

A CASE OF RECURRING LARYNGITIS HÆMORRHAGICA,  
by C. E. BEAN, M.D., of St. Paul.

#### AMERICAN MEDICAL ASSOCIATION.<sup>1</sup>

THIRTY-EIGHTH ANNUAL SESSION, CHICAGO, JUNE  
7TH, 8TH, 9TH AND 10TH, 1887.

At the Third Day's Session the committee on nominations, through its chairman, Dr. Brodie, of Detroit, submitted its report. There was some opposition to its adoption, but it was not strong enough to accomplish anything, and the report went through almost unanimously. It was as follows:

President, A. V. P. Garnett, Washington; vice-presidents, Duncan Eve, Nashville, Tenn., Darwin Colvill, New York, Charles J. O'Hagan, North Carolina, A. Stedman, Col.; secretary, W. B. Atkinson, Philadelphia; assistant secretary, J. S. Ransohoff, Philadelphia; treasurer, R. J. Dunglison, Philadelphia; trustees, L. Connor, Mich., E. O. Shakespeare, Pennsylvania, W. T. Briggs, Tenn.; judicial council, J. H. Murphy, Minn., J. M. Toner, Washington, J. R. Bartlett, Wis., A. B. Sloane, Kansas, X. C. Scott, Ohio, A. W. McClure, Iowa, J. W. Stormant, Kansas, J. F. Hubbard, Ind.

Cincinnati was recommended as the place of the next meeting, and the second Tuesday in May, 1888, as the time; and committees were also reported with the following gentlemen as chairmen: Necrology, J. M. Toner, Washington; State Medicine, J. C. Montgomery, Alabama.

#### RUSH MONUMENT.

The Committee on the Rush Monument reported that it was eminently appropriate to place a monument of Dr. Rush at Washington, and that the total subscriptions amounted to \$389. The report was adopted.

#### CREMATION.

The Committee on Cremation presented a report stating that it is only in cases of epidemics that the

value of cremation was really manifest, and as long as such things do not occur, no particular attention is paid to it. They, therefore, recommended that inasmuch as the present form of cremation does not meet with the approbation of the people, a just form of cremation should be adopted, by caustic lime or chloride of zinc being used to destroy the body speedily, and that people dying of zymotic diseases should be buried by the authorities. The report was referred to the section of State Medicine.

DR. F. M. JOHNSON, chairman of the Section on Obstetrics and Diseases of Women, read a paper in which antiseptic treatment is favored in obstetrical treatment.

DR. GEORGE H. ROHÉ, of Baltimore, Professor of Hygiene in the College of Physicians and Surgeons, read a paper on

#### RECENT ADVANCES IN PREVENTIVE MEDICINE,

of which the following is an abstract:

In the field of epidemiology and endemiology, the progressive extension of the fifth great pandemic of cholera first claims attention. Extinguished in the portions of Italy, France and Spain ravaged in 1885 and 1886, it has slowly invaded southeastern Italy, Hungary, and other Austrian possessions, and has been imported into South America, whence it threatens the United States by several routes. The danger of invasion of this country is at present greater than at any time within the past three years.

Yellow fever inoculation, as practised by Freire in Brazil, and Carmona in Mexico, has claimed a large share of the attention of sanitarians within the year. The claims made in favor of this method of preventing the scourge are now being subjected to an official investigation authorized by the United States government.

Diligent search has been made for the specific organism supposed to be the effective agent in vaccine virus, but without definite success. The results obtained are not entirely negative, however, and one may cherish the hope that a solution of this problem will soon be reached.

The relation of a peculiar disease of cows to scarlet fever, and the discovery of a specific microbe in the blood in the latter disease have attracted much attention. The restriction of scarlet fever will doubtless be more thoroughly effected as soon as physicians are convinced of its bacterial nature, and clearly comprehend its mode of transmission. Statistics were given showing what has already been accomplished in this field.

Sternberg, Fränkel and Weichselbaum have studied the specific microbe of croupous pneumonia, which the former regards as identical with his micrococcus Pasteuri; in which opinion both the other authors mentioned coincide. Dr. Baker, of Michigan, has also shown that croupous pneumonia seems to be dependent upon a cold dry atmosphere.

Measures for the restriction of pulmonary tuberculosis were adverted to. Tuberculous patients should not be treated in the same hospital wards with non-tuberculous individuals, and prompt disinfection of the sputa and other discharges should be practised, in order to diminish opportunities for infection. General sanitary measures should, however, not be neglected in the warfare upon the bacillus. There is danger that a too exclusive attention to the microbial factors

<sup>1</sup> Continued from page 591.

of disease will narrow our views of epidemiology, and preventive medicine.

It seems to be established that the microorganism discovered in the intestinal lesions and discharges in typhoid fever is the cause of this disease. The fact that this microbe may preserve its vitality for a considerable time in water and ice, has been shown by Bolton, Wolff, Hugel, Prudden and others. This, together with the well-known history of outbreaks of this disease, undoubtedly depending upon pollution of drinking-water, should make prompt measures of disinfection imperative in every case. The physician fails in his duty who neglects measures for the thorough destruction of the typhoid infection existing in the intestinal discharges.

The importance of disinfection of bedding, clothing, and other personal and household articles in contagious diseases demands that health authorities should have under their control establishments for disinfection, which can be carried out on a large scale and at public expense. Such institutions are now in use in Berlin, Disseldorf, Göttingen, Strasburg, Breslau, Leipsic, Danzig and other cities in Europe. The results are pronounced to be exceedingly beneficial. Steam under pressure is regarded as the best disinfecting agent.

Quarantine, a word which for more than five centuries has been synonymous with barbarism, is becoming under modern methods a safeguard to the public against infection and an advantage instead of obstruction to commerce. The results achieved at the model quarantine station at New Orleans, encourage the hope and almost warrant the prediction that the days of the quarantines of detention, whether by sea or land, are past, and that quarantine in future will mean simply thorough disinfection of fomites, and of course, effective isolation of persons already infected.

Cremation of garbage seems to be the best method yet devised for the inoffensive destruction or final disposal of solid city wastes.

The irrigation system of sewage disposal has steadily won favor. In Berlin, Breslau and Danzig, in Germany; Birmingham in England, and Pullman and other places in this country, it has been in successful operation. Chemical precipitation and purification of sewage has also been adopted with satisfactory results in various German cities. A board of distinguished engineers recently recommended the same system for the city of Providence, R. I.

Professor Vaughan's discovery of a very poisonous ptomaine in cheese, ice cream and milk undergoing certain chemical changes has been confirmed by a number of investigators in various parts of the country. Vaughan's suggestion that tyrotoxin may be found to be the poison that causes cholera infantum, opens up a new field of investigation in which every physician must of necessity be interested.

Analysis of food and drugs made during the year in Massachusetts and New York, show the wide extent to which adulteration is practised, and how the people are defrauded. Among the most startling instances are olive oil, of which 68 samples out of 91 were spurious. Vinegar was adulterated in 79 samples out of 116; mustard, 124 times in 211; white pepper, 63 times in 128; black pepper, 41 times in 71; mace, 29 times in 45. Of nine samples of horseradish examined, only one was found genuine. A precipitate of uncrystallizable sugar and coloring matter and chlo-

ride of tin (poisonous) is sold to candy-makers for making confectionery. Citrate of iron from respectable manufacturers contained three and one-half per cent. of quinine instead of twelve per cent. demanded by the pharmacopoeia. Authority and means should be given to the health authorities to protect the public from these frauds, many of which are a source of danger to life and health.

Statistics collected by the speaker show that five-sixths of the inhabitants of cities in this country have no facilities for bathing except such as are afforded by a pail and sponge, or an easily accessible river, lake, or other body of water. The establishment of public baths is urgently recommended, both as a sanitary as well as a moral measure. Tub or pool baths are objectionable both on account of expense and lack of privacy in the matter. The spray baths in use in the German and French army barracks are recommended. These are not expensive, either in first cost or administration, and allow each bather absolute privacy and the opportunity for a thorough cleansing in clean water. Public baths should be open the year round, and not only during the summer.

A number of instances are grouped together showing how the enforcement of appropriate sanitary measures has saved life. In Michigan, the saving of life from one disease (scarlet fever) has amounted during the past eleven years to 3,718, or 338 per year. In 1886 appropriate sanitary measures saved the lives of 298 persons who would have died of diphtheria if such measures had not been enforced. In England and Wales the average annual saving of life due to sanitary measures has amounted in the five years ending 1885, to 62,000. In Baltimore, a marked reduction of deaths from infectious diseases has followed the enforcement of certain sanitary precautions. In Memphis the death-rate has been reduced in six years from 35 per thousand to 23.80 per thousand. In Chicago the reduction in mortality in the last five years has been from 25.69 per thousand to 19.46 per thousand, a net saving of 17,214 lives in that city during that period.

While all advances in sanitary administration have doubtless contributed to produce these good results, the main influence is to be attributed to three factors. These are compulsory notification of infectious diseases, prompt and effective isolation of the sick and infected, and thorough disinfection of all infected articles and sources of infection. These must be the watchwords of the practical sanitarian of the future.

The report was sent to the committee on publication.

The Treasurer reported that the receipts of the Association during the year were \$21,723.32; disbursements, \$20,319.45; leaving a balance of \$1,403.77. The report was ordered filed.

The librarian reported that 158 titled works had been added to the library during the year, and that the library now contained 2,650 titled works, representing 7,500 volumes. There are 600 unbound volumes. He asked an appropriation of ten dollars for indexing. The report was ordered placed on file, and the ten dollars granted.

DR. GASTON moved that three members of the Association be appointed to act with the commission appointed by the President to investigate the Carmona system of inoculation for yellow fever. Adopted.

The Treasurer asked an appropriation from the

funds of the Association toward the expenses of the International Medical Congress.

Dr. DAVIS moved that \$500 be appropriated, but a delegate moved to amend by making it \$1,000, as the Illinois society had voted \$750. After some conversation, in which it was suggested that a subscription be taken up as well, so as to make the congress a financial success, the amendment was adopted and \$1,000 granted.

Dr. NATHAN S. DAVIS then submitted a resolution which he said he would call up for action at the session this morning. It was to the effect that the regular graduates of such dental and oral schools and colleges as required of their students a standard of preliminary or general education and a term of professional study equal to the best class of the medical colleges of this country be recognized as members of the regular profession of medicine, and eligible to membership in the association. He also submitted a resolution in reference to the annual banquets of the association, which, if adopted, will relieve the non-wine-drinking members from helping to pay the wine bills of the others.

(To be continued.)

#### RHODE ISLAND MEDICAL SOCIETY.

THE seventy-sixth annual meeting was held in Providence, June 9, 1887, the President, Dr. HORACE G. MILLER, in the chair.

The annual report of the Secretary showed the present active membership to be 199.

Dr. CHARLES H. LEONARD, Treasurer, read his annual statement. Income for the year, \$1,166.81; outgo, \$1,144.94. The printing fund has amounted to \$2,069.72. The building fund was increased to \$1,326.32.

Dr. J. W. MITCHELL reported verbally for the Building Committee, and the Society authorized the committee to examine suitably located buildings or sites with view to lease or purchase.

From the annual report of the Committee on the Library it appears that 1,014 volumes were added during the year. The Society's collection now includes 6,644 volumes and 3,000 pamphlets.

Dr. GEORGE L. COLLINS, on behalf of the Trustees of the Fiske Fund, announced that a prize of two hundred dollars had been awarded to Dr. James B. Field, of Lowell, Mass., for the best essay on Membranous Enteritis. The Trustees propose the following subjects for next year: I. "What changes has the acceptance of the germ theory made in measures for the prevention and treatment of consumption?" II. "Antisepsis in medicine and surgery; with original observations and experiments."

For the best essay worthy of a premium, on either subject, the Trustees offer a prize of two hundred dollars. Competing essays must be sent before May 1, 1888, to Dr. George L. Collins, Secretary of the Trustees of the Fiske Fund, Providence, R. I.

The following officers were elected for 1887-8: Horace G. Miller, President; Albert Potter, First Vice-President; John W. Mitchell, Second Vice-President; William R. White, Recording Secretary; George D. Hersey, Corresponding Secretary; Charles H. Leonard, Treasurer. Board of Censors: Ariel Ballou, James H. Eldredge, J. W. C. Ely, George P.

Baker, Benjamin Greene, Eugene Kingman, Job Kenyon, J. Howard Morgan.

Standing Committees were chosen as follows:

On Necrology, C. W. Parsons, Albert Potter, Eugene Kingman. On Publications, G. W. Porter, R. F. Noyes, C. M. Godding. On the Library, T. Newell, H. G. Miller, G. D. Hersey, G. W. Porter, G. L. Collins. On the Museum, W. J. McCaw, G. T. Swarts, F. B. Fuller, C. M. Godding, S. A. Welch.

The President announced the re-appointment of Dr. Frank B. Fuller on the Examining Board for a term of five years.

As recommended by the Censors, Drs. Irving S. Cook, James W. Craig, Franklin M. Eaton, Everett Flood, Elmer E. Moore, and John W. Keefe were admitted to Fellowship.

Dr. J. H. ELDRIDGE called attention to a case of criminal abortion which resulted fatally a few months ago, and concerning which the government has taken no action, though it is one of the few cases in which the facts are clearly established. As the present stringent law against abortion was secured through the efforts of this Society, Dr. Eldredge suggested the propriety of taking some action looking to its enforcement. On motion, the chair appointed a Committee of three, Drs. C. H. Fisher, G. W. Jenckes, and D. O. King, to press the prosecution of this and similar cases of malpractice.

The annual address was given by the President, Dr. Horace G. Miller, his subject being, "The Bacteriology of the Eye."

The annual dinner was served in Blackstone Hall, Dr. Charles H. Leonard presiding as Anniversary Chairman. After-dinner speeches were made by his Excellency Governor Davis, Rev. J. Hall McIlvaine, Drs. Henry W. Williams, of Boston, Benjamin E. Cotting, of Roxbury, A. H. Johnson, of Salem, Mass., P. Cassidy, of Norwich, Conn., E. Kingman, J. W. Mitchell, W. H. Palmer, T. Newell, H. G. Miller, O. C. Wiggin, and F. G. Eddy.

#### Recent Literature.

*Anatomy, Descriptive and Topographical, in 625 Illustrations.* By CARL HEITZMANN, M.D. English Edition. By LOUIS HEITZMANN, M.D. New York, J. H. Vail & Co. Vienna: W. Braumüller. London: Dulau & Co. 1887.

The success of Heitzmann's atlas, for it is an atlas to all intents and purposes, has been undeniable. It is not free from faults, but the clearness and beauty of the plates and the comprehensiveness of the plan have atoned for them. The work before us is a new edition intended for the English and American market. German words have been expunged from the plates and the text has been translated into English. We are told in the preface that it moreover has been often materially altered to bring it more in unison with English works.

This naturally suggests the question, what is the use of a text at all in a work of this kind? The names of the important parts appear on the plates, and the text is utterly insufficient as a description. The attempt to reproduce it in English has by no means improved it. Take as an example the account of the carpal bones. "Each bone presents six surfaces: a superior,

an inferior, a posterior or dorsal, an anterior or palmer, an internal or ulnar, and an external or radial surface. The dorsal surface of all the bones is convex, the palmer surface concave. The concavity of the palmer surface of the carpus is bounded by four prominences " . . . which are described very briefly. Now as Heitzmann includes the pisiform in the carpus, the statement that each bone has six sides is quite inadmissible, and even if it were true, whoshall say that such a statement is worth the making? By referring to the German of the first edition we see that in the second sentence the attributes of concavity and convexity are applied to the carpus as a whole, which one ignorant of the fact, would, we think, hardly suspect from the English. A worse mistake occurs in the account of the orbit. We could hardly believe our eyes when we read, "behind the circumference, superior — and externally lies the lachrymal groove," till the concluding words "*Fossa glandule lacrymalis*," explained that it was a mistake of translation and not of anatomy. Still it is inexcusable to translate "fossa" by "groove," especially as there is a lachrymal groove in another part of the orbit. On making further comparisons we met unexpected inaccuracies in the old edition which reappear in the new.

For instance, the shape of the patellar surface on the front of the femur is incorrect. The spiral twist of the esophagus round the aorta is greatly exaggerated. The view of the *zona orbicularis* at the back of the hip-joint is absurd. The author follows Weber in having a part of the ilio-femoral ligament make a loop under the neck of the femur with the above name. Even if some fibres take this course, which we do not believe, we know that they do not in the least resemble the strong band that is figured here. And after thus describing the ilio-femoral ligaments, the author or translator should have abstained from adding that "this is frequently designated the Y-ligament of Bigelow."

We find in both editions, the liver as flat as a pancake with a sharp edge in front and a thick one behind. If the author was not familiar with His's work, he might at least have copied from Quain. The folds of the peritoneum in the great omentum and meso-colon have given rise to much discussion, and we do not think that all the details are as yet surely settled. The first edition gave the old-fashioned diagram which, though incorrect, for the fœtus, may, we think represent the condition of the parts in the adult, but the figure in the new edition is the only one we know of which it can be said with absolute certainty that it is wrong at any stage and according to any theory. The plates of the brain are good, on the whole, but there certainly should be a horizontal one showing the lenticular nucleus and the knee of the internal capsule. A good addition is that of two plates showing injections of the sheaths of the tendons of the hand and wrist.

The plates are, for the most part handsome, but some seem to us decidedly inferior to the rest. If we have been severe in our criticisms it is because the success of the work has brought it into prominence and we feel that before bringing out a new edition especially designated for new fields, the author should have corrected old errors and have brought the work fully up to the times. If this is to be considered as the artistic work of an amateur in anatomy, it deserves high praise, which must be withheld if the author enters the anatomical ring as a "professional." T. D.

## THE BOSTON Medical and Surgical Journal.

THURSDAY, JUNE 23, 1887.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,  
94 BOYLSTON STREET, BOSTON, MASS.

### THE CROWN PRINCE OF GERMANY.

RECENT numbers of the foreign medical journals furnish us with accounts of the illness of the Crown Prince, from which we gather the following details. It appears that His Imperial Highness's voice has been somewhat altered in quality since his trip to Italy last autumn, but, according to the *Lancet*, it was not until January that he "began to suffer from slight hoarseness, and early in March, Professor Gerhardt discovered a warty growth attached to the left vocal cord, which he treated by touching with the electro-cautery. Its size having been reduced by this means, the Prince was advised to go to Ems, where he remained about six weeks. On his return he was found to be no better as regards his hoarseness, and the growth had somewhat increased in size. Professor Tobold was then called in, and after a consultation with the Emperor's and Crown Prince's physicians, Von Lauer and Wegner, it was thought that the growth was of a malignant nature, and at their request Dr. Bergmann's opinion was sought. He was inclined to confirm the diagnosis. It was decided that an external operation was necessary, but whether it was to be excision of the larynx or thyrotomy was not settled definitely. In consequence of the strong feeling at Court that this operation ought not to be done unless absolutely unavoidable, on account of its attendant danger to life and great impairment of voice, even if successful, Dr. Bergmann declined to take the responsibility as the operator, unless the impossibility of the removal of the growth by intra-laryngeal methods was confirmed by Dr. Morell Mackenzie. Immediately on arriving in Berlin, on Friday, May 20th, a consultation was held, at which Dr. Mackenzie met all the medical men above mentioned. On making a laryngoscopic examination, Dr. Mackenzie found a sessile growth about the size of a large split pea, but in shape more elongated, attached to the posterior portion of the left vocal cord on its inner and upper surfaces. He urged that the more serious operation should not be performed before a portion of the growth had been re-

moved for microscopic examination. This had not been done because it was considered impossible, owing to its small size and sessile character. The following morning another consultation was held, at which Dr. Mackenzie succeeded in removing with forceps a small piece of the growth. Professor Virchow, having examined microscopically the portion taken away, pronounced it to be a benign growth. He said that the epithelial cells were increased in size and number. He further stated that, as the portion removed included a complete section of the growth and the surface of the vocal cord beneath, as clearly demonstrated by the presence of some of the longitudinal elastic fibres of the latter structure, he considered that there was no reason to suppose that any remaining portion of the growth was of a cancerous nature."

Dr. Mackenzie, as we are informed by cablegrams in the daily papers, has made a second visit to Berlin, and again succeeded in removing a portion of the growth. He is reported as adhering to the opinion that the growth is of a benign, warty character, while the German physicians seem to be inclined to regard it as cancerous. The diagnosis of these cases often presents the greatest difficulty, yet it is just in such instances that it is of the highest importance, as the proper treatment depends upon the nature of the neoplasm. If it be a simple papilloma, it can be readily and successfully attacked by intra-laryngeal methods. If it be of a malignant nature, it becomes a question of partial excision of the larynx. By recognizing intra-laryngeal malignant disease in its earliest stage, when but a small area of one portion of the organ is involved, and unaccompanied by swollen glands or much inflammatory disturbance, good results may be expected by removing the diseased tissue. When, however, the disease has progressed so as to involve both sides of the larynx, total extirpation of the organ can hardly be considered a justifiable procedure. We trust that Dr. Mackenzie's diagnosis will prove to be correct in the case of the Crown Prince. He is supported in his opinion by the high authority of Prof. Virchow who, from his microscopic examination of the second portion of the growth removed, pronounced it a pachydermia verrucosa; there were enlarged papillae and epithelial cells, but no morbid products in the submucous tissues. Whatever the result of this difficult case may be, Dr. Mackenzie's wise and timely counsel at least postponed a serious operation, and it is not likely that this able laryngologist will allow the moment to pass when partial excision of the larynx would be too late. If he has prevented a removal of the larynx, and effects an ultimate cure, it will be a triumph for laryngeal surgery and diagnosis impossible to exaggerate, and of which not only laryngologists, but the profession in general, will be proud.

— Ten per cent. of the students in the University of Zurich are women. 29 of them are studying medicine, 14 philosophy, and 2 political economy. There are now 48 female students of medicine in London, and in Paris 103.

#### THE REGULATION OF MEDICAL PRACTICE IN MAINE.

THE readers of the JOURNAL will probably recall the "Druidic University" of Maine and the remarkable story of the reporter who procured a degree from that institution during the past winter. The exposure of the institution was followed by the introduction in the legislature of a bill for the registration and licensing of physicians. The bill was passed and signed by the governor. Subsequently, however, the governor recalled the bill, erased his signature and sent a veto message to the legislature. This somewhat singular conduct called forth a series of resolutions from the Maine Medical Association, which deal very plainly with the subject. The resolutions, which were unanimously adopted rehearsed the circumstances of the case, and proceeded as follows:

*Resolved*, That as this association possesses fuller knowledge of the circumstances of the case than any other body of citizens, it is peculiarly its duty to inform the people of the State of the outrage which has been perpetrated upon them and acquaint them with the conduct of the men whom they have honored with some of the most exalted offices in their gifts.

*Resolved*, That in the opinion of this association, the governor, by abstracting the registration act from the statutes of the State, has violated his oath of office which requires him to uphold and execute, rather than to overturn and destroy, the laws.

*Resolved*, That his refusal to submit the question of legality of his performance to the Supreme Court, knowing that no other man could obtain its opinion on the matter during the present administration, is an admission of the indefensibility of his attitude, and displays either the disposition of a despot or servility of a pusillanimous agent of unscrupulous political masters.

*Resolved*, That as a body of citizens who believe that the safety of our constitutional liberty depends upon the support and faithful execution of all laws which are legally made, and who are unwilling to submit without protest to atrocious imposition, this association looks with great alarm upon the effort of our chief magistrate to defeat the will of the people by attempting to overthrow the statute, whatever opinion of its merits were entertained by him or his advisers.

*Resolved*, That this association will use all honorable means in its power to procure restoration of the registration law to its just place among other statutes of the Commonwealth, and calls upon every citizen who values his rights to assist in this patriotic work with his voice, and if necessary his vote.

The exposure and subsequent legislation gain added interest to the people of Massachusetts from the fact that the former director of the Druidic University has already settled in Boston and offers his services to any who may desire them through the medium of the Boston press.

#### MEDICAL NOTES.

— Our readers will observe that in this and the two preceding numbers of the JOURNAL we have introduced supplementary pages, to make room for our full reports of the various State and National medical societies that have held their sessions recently.

— The President of the Board of Health at Key West reports twenty-six cases of yellow fever, and nine deaths up to June 14th. Subsistence supplies and medicines are being furnished the yellow-fever hospital from the Marine Hospital stores at Key West.

— The late Paul Bert once, *experimenti gratiâ*, had himself vaccinated and then inoculated with virus from a man dying with small-pox. He did not take the disease.

— The Paris correspondent of the *Therapeutic Gazette* relates the particulars of a suit, interesting from the point of view of life insurance. It is well known that the French law makes it a penalty for a physician, surgeon, pharmacist, or midwife to divulge secrets which he has learned in a professional capacity. That this law is not a dead letter was shown by the fact of the conviction some two years ago, of Dr. Watelet, who to vindicate himself from a published criticism as to his treatment of a certain case, wrote to a daily paper an account of the symptoms, for which he was promptly prosecuted by the District Attorney without the intervention of the family supposed to be aggrieved, and condemned to pay a fine. The publisher of the article was also fined, and on appeal, both sentences were confirmed. Now a French physician of Besançon was called upon after the death of a patient of his, to furnish the life insurance company with a certificate of the cause of death. This, remembering the law and the fate of Dr. Watelet, he refused to do. Thereupon, the heirs began a civil action against him and the insurance company, including both as co-defendants, so as to obtain the money either with or without the certificate. Before the court the doctor's plea was the penal statute enjoining professional secrecy; that of the company, the policy clause providing for the production of a death certificate. The court accepted the doctor's defence, exonerating him, free of all costs, and ordered the company to pay the full amount demanded, together with all the expenses and costs of the lawsuit.

— The reading and recitation term of the Long Island College Hospital, which began in March, closed early in June. During the three months' session, the students have had the advantages of the new maternity wards of the Hospital, and have attended two abortions and seventeen confinements. In attendance upon these cases, they witnessed the following complications and operations: Complete inversion of uterus and its reduction, one; placenta prævia, two; transverse presentations, three; twins, one; hydrorrhea (post-partum), one; forceps deliveries, two; breech, two; version, external, two; version, internal, one; restoration of perineum, three; curetting after abortion, two.

#### BOSTON AND NEW ENGLAND.

— The tenth annual report of the managers of the Adams Nervine Asylum has reached us, covering the year ending April 30, 1887. The report of the resident physician, Dr. S. G. Webber, shows 108 cases treated during the year, the admissions having been 80. Against this latter number, we find 296 applications for admission. Of these, 111 were rejected for various reasons, leaving 185 who were more or less suitable for treatment. As will be seen, less than one-

half of these women could be received. The average stay of all the patients was 4.27 months; of those who recovered, 4.47 months; of those who were relieved, 5.07; and of those not relieved, 1.63 months. The greatest number of the patients admitted were from twenty-five to thirty years of age, and nearly three-fourths of all were unmarried. The expenses of the year were about \$35,000, of which \$8,565 was collected from patients, leaving over \$26,600 to be paid from the funds of the Asylum.

#### NEW YORK.

— At the last meeting of the Academy of Medicine the present season, held June 16th, reports from the various sections were read, and Dr. Laurence Johnson read a memorial of the late Dr. E. Darwin Hudson. Later in the evening, the President, Dr. A. Jacobi, entertained the Fellows of the Academy and their friends at a reception at his house, and the members of the Orthopaedic Association went there in a body from their dinner at the St. Nicholas Club.

— An inmate of the city insane asylum on Ward's Island, having died under somewhat suspicious circumstances, an investigation of the case has been made by a coroner's jury, which rendered a verdict to the effect that the immediate cause of the man's death was violence used by two of the attendants. They also censure the examining physicians for not giving a more correct account of the cause of death. The two attendants referred to have been committed to the Tombs to await the action of the Grand Jury.

— The American Orthopaedic Association was successfully inaugurated on the 15th. The organization committee consisted of Drs. Gibney, Shaffer, and L. H. Sayre, and their arrangements for the meeting, which occupied two days, were most satisfactory in every way. The scientific proceedings were of a somewhat impromptu character, no formal programme having been made out, but were full of interest and value. From a social point of view, the gathering was a delightful one, and all honor for their generous hospitality is due the organization committee, who, on the evening of the 16th, secured for the Association and a few guests three boxes at the Casino, where the comic opera of "Erminie" is running, and on the following evening gave a most elaborate and enjoyable dinner at the St. Nicholas Club. At the latter, informal speeches were made by Drs. Lewis H. Sayre, W. T. Bull, Gibney, Shaffer, Bradford, of Boston, and A. S. Roberts, of Philadelphia. At the meeting, the following officers were elected: President, Dr. Shaffer, of New York; Vice-Presidents, Drs. Bradford, of Boston, and A. S. Roberts, of Philadelphia; Secretary and Treasurer, Dr. L. H. Sayre, of New York. Among those present, were Drs. Morton and A. S. Roberts, of Philadelphia; Bradford, of Boston; Packard, of Hartford; Hodgson, of St. Louis; and L. H. Sayre, Shaffer, Gibney, Stillman, Judson, Ketch, Ridlon, Berg, Dillon Brown, Knickerbocker, H. L. Taylor, Develin, and C. W. Stimson, of New York.

— Dr. John Q. Bird, for three years President of the Board of Police of Jersey City, and recently appointed one of the visiting-staff of the Jersey City Hospital, died of septicæmia on the 17th of June. The first patient whom he attended at the hospital was an Italian who had both his legs broken in a railway accident, and the case terminated fatally. In making the autopsy he received a slight cut on one of his fingers, which was promptly treated with carbolic acid. Violent inflammation set in, however, and in spite of the most active exertions of Dr. T. R. Varick, the surgeon in attendance, fatal blood-poisoning resulted. Dr. Bird was about forty years of age, and for the past seventeen years had been connected with the Jersey City Police Department, either as police surgeon or as a member of the governing board. He leaves a widow and four children.

— The Board of Aldermen having recently adopted some resolutions in regard to food adulterations, Mayor Hewitt has sent to that body a report from the Board of Health on this subject, in which it is stated that the experience of the department has been that cases of hurtful adulteration of food and liquor are comparatively rare. The adulterations usually encountered are made in the interest of bulk and cheapness, and the materials used for this purpose are seldom in any other respect hurtful, than that they are likely to be indigestible. In the case of liquors, even of imitation wines, into which no grape-juice enters, it has been found that, if the alcohol is eliminated, only the fruit-syrups of the soda fountain remain. It is difficult, if not impossible, to find on sale in New York a sample of confectionery with poisonous coloring or flavoring. There has also been a marked improvement in the character of the milk and meat supply of the city, and such adulterations as are known to exist are simply frauds on the purchaser, which, as frauds, do not come under the notice of the Board. "The dangers with which our sense of duty prompt us to cope with most vigorously," the report goes on to say, "are those arising from the sale of contaminated food. This we are doing as well as we are able, considering the insufficient means at our command. . . . I am of the opinion that the statements published by the authority of the American Society for the Prevention of the Adulteration of Food, quoted in the resolutions of the Common Council, greatly exaggerate the facts — not as to the prevalence of adulteration, but as to the effect upon the public health of the kinds of frauds perpetrated."

— Notwithstanding the boasted efficiency of the hospital ambulance service in New York, there seem, at times, to be defects in its working, and a very serious case of apparent negligence has just been reported to the Commissioners of Charities and Correction by Mayor Hewitt, from facts coming within his immediate knowledge. In a letter to the Commissioners, he states that about ten o'clock on the morning of June 8th, a painter who was working on a house across the street from his own residence fell, and was

crushed to a shapeless mass, although life was not extinct. The accident was witnessed by his (Mayor Hewitt's) family, and a gentleman who was present immediately sought the police to give a call for an ambulance. No ambulance, however, arrived, and at length Mr. Hewitt sent specially to Bellevue Hospital for the purpose of procuring one. He was informed that there was no ambulance available. In the meantime, a call had been made upon the New York Hospital, and the answer came back that they declined to send an ambulance. At length, after three-quarters of an hour, during which the man lay in a dying condition upon the sidewalk, Mr. Hewitt availed himself of the offer of a friendly driver of a spring wagon, and the man was conveyed to the hospital. "I cannot imagine," concludes Mr. Hewitt, "that he will recover from the serious injuries that he received, but certainly no one who witnessed the scene will ever forget the impression of inhumanity which must have been made upon him as he realized that the public arrangements at Bellevue and the New York Hospital were entirely unavailable for a poor, suffering creature. I can understand that the call upon the ambulance at Bellevue Hospital may have exhausted the supply, and that occasionally it will happen that delay of this sort will occur; but I particularly call your attention to this case in order that, if there be any lack of proper provision of ambulance service at the hospital, it may be supplied at once."

### Miscellany.

#### ABSTRACT OF ADDRESS DELIVERED BY M. CHARCOT AT THE FUNERAL OF M. VULPIAN.<sup>1</sup>

I HAVE accepted the painful duty of expressing, in the name of the Section of Medicine and Surgery, the sorrow felt in the Academy of Sciences at the unexpected loss of one of its members who has most honored and best served it. But I fear the duty is very difficult to perform.

I met Vulpian first thirty-seven years ago at the hospital of la Pitié, which we had both entered as internes. We were both Parisians, in our twenty-fifth year. A perfect fellowship of sentiments, of ideas, of tendencies, even of difficulty in self-support, quickly united us; it was for life.

My new colleague was even then attached to the Museum of Natural History. From the beginning of his career Vulpian divided his activity between the laboratory and the wards of the hospital. He was early led to understand that without the assistance of experimentation, simple observation is often lacking in power; while, on the contrary, experimental data, at least so far as concerns human pathology remains almost always without legitimate application when it is not constantly submitted to clinical control. The great characteristic of Vulpian's scientific life is this, that intimate union of the physician and the experimenter.

Nominated physician to the hospital in 1857, *agrégé*

<sup>1</sup> Archives de Physiologie, March, 1887.

of the Faculty of Medicine in 1860, Vulpian was called in 1864 to succeed Flourens at the Museum of Natural History in the chair of comparative physiology, which he occupied until 1866. The success of the young professor was brilliant. At each step he gave proof of a maturity of mind and an elevation of thought whose precocity is not less admirable than their greatness.

In 1866 he published "*Leçons sur la Physiologie générale et comparée du Système Nerveux*." At the death of Jean Cruveilhier the chair of pathological anatomy became vacant in the Faculty of Medicine of Paris, Vulpian was nominated. His election met the most active resistance on the side of the irreconcilable partisans of the ancient methods. Microscopic pathological anatomy, purely descriptive, had had its time. The microscope was now needed to penetrate the interior of the organ, to study the lesions of the anatomical elements. Vulpian, alone, among the *aggrégés* at that time, was sufficiently prepared by his earlier studies to accept the responsibility of such a weighty task.

In 1872, he occupied the chair of experimental and comparative pathology left vacant by the retirement of our eminent confrère, Brown-Séquard. This was for Vulpian a return to the studies of his choice. During this period, terminated by his death, he published some of his most important works; in 1875 "*Leçons sur l'appareil vasomoteur*." In this he demonstrates the dilating action of the chorda tympani on the vessels of the tongue. "*Leçons sur l'action Physiologique des Substances Toxiques et Médicamenteuses*" (1881) contain remarkable studies in regard to jaborandi, curare, strychnia. Finally in "*Traité des Maladies du Système Nerveux*" are found the innumerable observations and discoveries made by Vulpian in the domains of nervous pathology.

His works on physiology are found in memoirs and publications and reports of various societies. That which characterizes Vulpian as a physiologist is the absolute exactitude, the methodical arrangement and the extreme moderation in his conclusions.

May 22, 1876, Vulpian attained the object towards which he had directed all his efforts, he was received into the Institute, succeeding Andral.

Vulpian can be characterized by one word; he was the man of duty. Never was he seen to hesitate before a task which he had undertaken to perform. When he felt himself becoming feeble he resigned as physician to the Hotel-Dieu, and gave up his private practice.

Vulpian was a great and good heart, a family man, ready to sacrifice all for his own, a master adored by his pupils, a firm and devoted friend. He has had few enemies; in his rivalries he showed loyal, generous, chivalric emulation.

### Correspondence.

#### POISONING BY IVY.

[As the season for ivy-poisoning is developing, the following graphic account of his own case by a sufferer, may not be without interest to the profession, though coming from a layman.]

MR. EORTON.—Early in September I cut with a scythe

some "poison-ivy," so called (botanical name "*Rhus toxicodendron*,") growing along a fence around the garden of the house I then lived in at Natick, Mass. It had previously blossomed, and the fruit was then formed. I touched it with my hands, I suppose, five or six times during the half hour I was cutting it down. The next day I noticed during the morning a slight tingling sensation in the eyes.

The seat of the pain seemed to be on the inner side of the lids and not in the eye itself. I supposed it to be due to excessive use of my eyes, or to reading or writing on the cars, which I frequently did for half an hour morning and evening. The pain soon developed into itching, which continued with increasing severity for two or three days. Towards evening my face also began to itch and was slightly swollen. Up to this time no eruption was noticed, but no very careful examination was made. During the night the swelling increased a little but the itching was intense and unremitting, especially near the eyes.

The next morning small pimples or vesicles were visible beneath the skin over the whole surface of the forehead, about the eyes and face, being most prominent where the itching had first begun, but visible everywhere, in some places very near together. This was accompanied by so much swelling of the face that it was with great difficulty I could see at all. Twenty-four hours later the pimples had become plainly visible where they could previously be distinguished only with great difficulty. They gradually assumed the appearance of small blisters, filled with a fluid resembling water, which could be easily broken by squeezing, or when smartly rubbed. With the formation of the vesicles, the itching began to subside, but returned at intervals for three or four days, while the skin gradually healed, the old cuticle peeling off as the new one was formed. From the forehead and eyes the eruption had gradually extended over the portions of the face not covered by the hair and whiskers, as far as the ears, where it remained longer than almost anywhere else. It began to appear on my hands about three days after beginning on my face, when it followed substantially the same course, but lasting perhaps two or three days longer. In a week after being attacked my hands were at the worst stage.

The disease next proceeded to my feet and ankles and a narrow area on the inside of each thigh about 20 or 25 centimetres long, by 4 or 5 centimetres wide (except in one small place where it was perhaps 8 centimetres wide). On the feet it was confined for a few days to the outside and inside of the rear part of the ankle. From thence it gradually extended over the whole surface of the foot, subsiding after about a week, except at the places where it had first appeared, from which I could not dislodge it for a week or ten days longer. The feet were not as painful during the day as the hands and face had been, but at night the difference was far more than made up by the most horrible itching I have ever experienced, which continued with short intervals of comparative comfort during the whole night. No pain I ever had was anything like so intolerable.

The general progress of the disease everywhere was as I have indicated it on the face, namely, first the tingling and itching, then the appearance of pimples, gradually changing to blisters and as gradually subsiding in a few days. In three or four weeks after the first attack the disease had almost disappeared. During its last stages there appeared on my body, particularly on my back, red blotches or pimples of quite large size which were somewhat painful for two or three days, but which then grew smaller and disappeared without discharging anything. I do not know whether or not they had any connection with the ivy-poisoning.

I began trying so-called "remedies" as soon as I became aware what the trouble was. Nearly every person I met knew of and recommended to me a remedy certain to cure the disease in a day or two, but of all I tried none seemed to check in any degree its progress. It seemed to run its regular course everywhere, in spite of anything I could do. I began bathing the parts affected with dilute bay rum; then I used Pond's extract of Hammamelis, and afterwards

what I supposed might be a stronger extract, put up by an apothecary in Boston. This was applied externally several times a day, and taken internally two or three times daily, in doses of about one-fourth teaspoonful.

It appeared to have no permanent effect, but rendered the itching somewhat more tolerable as long as the surface was wet. After this I tried a solution of bicarbonate of soda, and receiving no benefit, I next used a solution of acetate of lead with no perceptible effect. Then I tried tincture of lobelia, as procured from the druggist, diluted with ten times its bulk of water. This did relieve the itching to some extent, but to nothing like the degree I was led to expect from the accounts I heard of its use by other people. My physician at last recommended to me a solution of one part of bichloride of mercury diluted with one thousand parts of water. This, when applied often, relieved the itching to a great extent (but not entirely), and the disease then became much more easily endurable. I obtained the greatest relief by bathing the parts affected

alternately with the mercurial solution and a very weak gruel, made from indian meal and hot water, and allowed to get cold before using. Had I used these remedies when the disease first made its appearance, I think I should have suffered comparatively little discomfort. I also tried later the fluid extract of *Grindelia robusta*, diluted with alcohol so as to feel only a little sticky when applied to the skin. This, applied often, considerably allayed the itching, but not to the same degree as the mercurial solution.

Nothing, however, seemed able to check or much retard the process of the disease: when it appeared in a part it ran its course in from about four to seven days, and then gradually subsided. The wrists and ankles had slight eruptions and periods of itching for a few days at a time at intervals for several months afterwards, especially in warm weather, but these symptoms gradually disappeared, and entire relief from the attacks was at length obtained.

Very truly yours,

GEO. W. BLODGETT, *Civil Engineer.*

# REPORTED MORTALITY FOR THE WEEK ENDING JUNE 11, 1887.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2,061: under five years of age 466; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoal diseases, whooping-cough, erysipelas and fevers) 466, consumption 327, lung diseases 195, diarrhoal diseases 127, diphtheria and croup 123, measles 45, typhoid fever 35, scarlet fever 18, whooping-cough 17, malarial fever 14, cerebro-spinal meningitis 13, erysipelas seven, puerperal fever seven, small-pox (New York) two. From typhoid fever, Philadelphia 13, Boston five, Baltimore four, New York and Pittsburgh three each, New Orleans two, District of Columbia, Lawrence, Haverhill, Malden and Waltham one each. From scarlet fever, New York seven, Philadelphia four, Brooklyn three, Boston, Baltimore and District of Columbia one each. From whooping-cough, Philadelphia six, Baltimore three, New York, Brooklyn, Boston, New Orleans, District of Columbia, Pittsburgh, Nashville, and Fall River one each. From malarial fever, New York seven, Brooklyn four, District of Columbia two, Balti-

more one. From cerebro-spinal meningitis, New York nine, Baltimore, New Orleans, District of Columbia and Haverhill, one each. From erysipelas, Philadelphia three, New York, Brooklyn and Boston, one each. From puerperal fever, New York, Philadelphia, Brooklyn, Boston, Portland and Lowell, one each.

In the 28 greater towns of England and Wales, with an estimated population of 9,244,059, for the week ending May 28th, the death-rate was 20.4. Deaths reported 3,621: infants under one year of age 810; acute diseases of the respiratory organs (London) 3,333, measles 251, whooping-cough 143, scarlet fever 52, diarrhoal diseases 31, diphtheria and croup 23, fever 22.

The death-rates ranged from 15.7 in Sunderland to 32.3 in Manchester; Birmingham 17.2; Blackburn 20.1; Hull 23.9; Leeds 17.7; Leicester 17.1; Liverpool 25.3; London 19.0; Newcastle-on-Tyne 25.9; Nottingham 19.2; Sheffield 20.1. In Edinburgh 20.2; Glasgow 23.1; Dublin 24.1.

The meteorological record for the week ending June 11, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending Saturday, June 11, 1887.	Barom- eter.	Thermometer.		Relative Humidity.				Direction of Wind.		Velocity of Wind.		State of Weather.		Rainfall. Duration, Hrs. & Min. Amount in Inches.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 11, 1887, TO JUNE 17, 1887.

BAXTER, J. H., colonel and chief medical purveyor. To proceed to New York City for the purpose of inspecting the medical purveying depot at that place. S. O. 133, A. G. O., June 10, 1887.

PAR. 15 S. O. 52, A. G. O., March 5, 1887, is so amended by Par. 9, S. O. 133, A. G. O., June 10, 1887, as to direct that Major Chas. H. Alden, Surgeon, be relieved from duty in Department of Dakota, about June 20, 1887, and he is granted leave of absence from the date when so relieved to include August 27, 1887.

FRYER, B. E., major and surgeon. Found incapacitated for active service by an Army Retiring Board and granted leave of absence until further orders on account of disability. S. O. 133, A. G. O., June 10, 1887.

HALL, JNO. D., captain and assistant surgeon. Leave of absence extended one month. S. O. 136, A. G. O., June 14, 1887.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING JUNE 18, 1887.

WALTON, THOMAS C., surgeon. Ordered June 15, for examination preliminary to promotion as medical inspector.

PRICE, A. F., surgeon. Detached from special duty, Annapolis, Md., proceed home and wait orders.

FLINT, JAMES M., surgeon. Detached from the "Albatross" and ordered to the Smithsonian Institution.

WILLSON, W. G. G., passed assistant surgeon. Ordered to the Receiving Ship "Independence," Mare Island, Cal.

#### SOCIETY NOTICE.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—The Thirty-sixth Meeting of the Association will be held in the building of Columbia College, at New York, from Wednesday morning, August 10, until Tuesday evening, August 16, 1887. For all matters pertaining to membership, papers and business of the Association, address the Permanent Secretary, Mr. F. W. Putnam, at Salem, Mass., up to August 6th. From August 6th until August 17th, his address will be Columbia College, New York, S. Y.

#### ERRATUM.

In the account of operations at the City Hospital before the Massachusetts Medical Society, June 7th, three cases of cataract are mentioned as operated on by Dr. Williams, according to von Graefe's method: whereas the mode employed was, extraction through a corneal flap of medium size, as recommended by Lebrun, Liebreich, von Wecker, and others.

#### BOOKS AND PAMPHLETS RECEIVED.

Report of the Commissioner of Education for the Year 1884-85. Washington: Government Printing Office. 1886.

Wiener Klinik. Vorträge aus der Gesamten Praktischen Heilkunde ridgirt von Dr. Anton Bum. Die Mechanische Behandlung der Lumbago. Von Dr. J. Schreiber. Wien, 1887.

Granular Conjunctivitis with and without Pannus. By W. Cheatham, M.D. (Reprint.)

Twenty-Ninth Annual Report of the Washingtonian Home, 41 Waltham Street, Boston. 1887.

Transplantation of a Rabbit's Eye into the Human Orbit. By Charles H. May, M.D. 1887. (Reprint.)

A Contribution to the Pathology of the Cerebellum. By E. C. Seguin, M.D. New York: J. H. Vall & Co. 1887. (Reprint.)

Infants, their Chronological Progress. By Prof. Stanford E. Chaillet, M.D., Tulane University of Louisiana. 1887. (Reprint.)

Mental Epilepsy. By L. W. Baker, M.D., Superintendent Hospital Cottages for Children, Baldwinville, Mass. 1886. (Reprint.)

A Case of Internal Hydrocephalus, due to Disease (Thombotic) in the Wall of the Straight Sinus. By Wm. Browning, M.D., of Brooklyn. 1887. (Reprint.)

Stricture of the Urethra: its Diagnosis and Treatment facilitated by the Use of Simple Instruments. With Original Wood Engravings. By E. Distin-Maddick, F.R.C.S., Edinburgh, Late Surgeon Royal Navy. London: Baillière, Tindall & Cox. 1887.

The Cremation of the Dead considered from an Æsthetic, Sanitary, Religious, Historical, Medico-Legal and Economic Standpoint. By Hugo Erichen, M.D., with an Introductory Note. By Sir T. Spencer Wells, Bart., F.R.S. Illustrated. Detroit: D. O. Haynes & Co. 1887.

The Physicians' Dose and Symptom Book, containing the Doses and Uses of all the Principal Articles of the Materia Medica and Official Preparations. Arranged in Alphabetical Order, etc. By Joseph H. Wythe, M.D. Sixth Edition. Completely rewritten and enlarged. Philadelphia: P. Blakiston, Son & Co. 1887.

Die Allgemeine Pathologie oder Die Lehre von den Ursachen und dem Wesen der Krankheitsprocesse von Prof. Dr. Edwin Klebs. Erster Theil. Die Krankheits-Ursachen. Allgemeine Pathologische Physiologie. Mit 66 Theilweise Farbigen Abbildungen im Text und 8 Farbatfeln. Jena: Verlag von Gustav Fischer. 1887.

The Vest-Pocket Anatomist (founded upon Gray). By C. Henri Leonard, A.M., M.D., Professor of the Medical and Surgical Diseases of Women in the Detroit College of Medicine. Thirteenth Revised Edition, Enlarged by Sections on Anatomical Triangles and Spaces, Hernia, Gynecological Anatomy and Dissection Hints. Detroit: The Illustrated Medical Journal Co. 1887.

A Treatise on Diphtheria, Historically and Practically Considered, including Croup, Tracheotomy, and Intubation. By A. Sanné, Docteur en Médecine. Ancien des Hôpitaux de Paris, etc. Translated, Annotated and the Surgical Anatomy added. Illustrated with a full-page colored lithograph and many wood engravings. By Henry Z. Gill, A.M., M.D., LL.D. St. Louis, Mo.: J. H. Chambers & Co. 1887.

A Practical Treatise on Diseases of the Eye. By Dr. Edouard Meyer, Prof. à l'Ecole Pratique de la Faculté de Médecine de Paris: Chevalier of the Legion of Honor, etc. Authorized Translation by Freeland Fergus, M.B., Assistant Surgeon, Glasgow Eye Infirmary. Colored Plates printed under the Direction of Dr. Richard Liebreich, M.R.C.S., Author of the Atlas of Ophthalmoscopy. With Colored Plates and 267 Engravings on Wood. Philadelphia: P. Blakiston, Son & Co. 1887.

## DIRECT FUNCTIONAL MURMURS AND OBSTRUCTIVE SAFETY-VALVE ACTION IN THE HEART.

BY JOHN GUTHRIE, M.D.,  
Passed Assistant Surgeon, United States Marine Hospital Service,  
Charleston, S.C.

In a report of several cases of malignant aortic aortitis published in the *Medical News* of November 14, 1885, I dwelt upon the significance of a mitral, direct (præsyntolic) murmur, which was proved by the autopsy, to have been unconnected with any lesion of the mitral orifice. The lesions found were those of an intense aortic regurgitation, and I concluded that the mitral direct murmur was due to the fact that, in default of the semi-lunar valves, the recoil of blood fell, during the diastole, upon the mitral valve, holding its leaflets tense and raised against the stream of blood coming from the auricle. The conditions were, therefore, recognized to be the same with those first described by Flint.<sup>1</sup> As far as I know, this is the first case recorded in support of the views held by Professor Flint. I regret deeply that we cannot have today the aid of his opinion to decide whether I am right or not in giving these views a much wider field of application. In the opinion of Professor Flint the existence of this direct functional mitral murmur was limited to a very small number of cases of aortic regurgitation; and indeed this limitation was held up as an argument against his views by Dr. Balfour, of Edinburgh. This observer claimed that Flint's murmur ought to be heard in all cases of aortic regurgitation, and that even in health the mitral cusps are floated up towards the auricle by the blood filling the ventricle in the normal process. He forgets, it seems to me, that in aortic regurgitation the leaflets are not floated upwards, but are actively driven against the auricular blood by the force of the general arterial tension. Now, it is one of the objects of this paper to show that the functional mitral murmur is by no means as rare as Dr. Flint believed it to be.

The diastolic murmur heard at the apex in aortic insufficiency is generally supposed to be a transmitted aortic murmur. Dr. Balthazar Foster claimed that this propagation is of diagnostic value as indicating a lesion of the posterior (mitral) aortic leaflet, because in such cases the regurgitant current trends towards the apex. I maintain that these propagated murmurs are in fact mitral obstructive murmurs, and that they are more apt to develop when the posterior aortic segment is affected, because in such cases the recurrent stream is brought to bear directly against the anterior leaflet of the mitral valve.

However this may be, the fact remains, I believe, that obstructive functional mitral murmurs are of frequent occurrence in aortic regurgitation. In three cases of this lesion that I have studied since the publication of my paper, the mitral murmur was readily detected. It is not difficult to separate the two murmurs. The diastolic fades perceptibly towards the end of the diastole, whilst, at the apex, a very distinct præsyntolic accentuation precedes the imperfectly developed first sound. This feebleness of the first sound is also a result of the præsyntolic tension of the mitral valves.

The following is an abstract from my notes of these cases:

<sup>1</sup> Treatise on Diseases of the Heart, second edition, p. 367.

CASE I. A. G., aged thirty-seven, colored. Physical signs: The superficial veins are prominent. The arterial pulsation is marked at the neck and the extremities. The apex beat is four-and-three-quarters inch below, and two to the left of the nipple. Palpation shows it to be a sustained impulse. During its slow collapse there is a smaller secondary impulse which corresponds with the recoil from a slight visible retraction which occurs at the moment of the systole.

Percussion denotes the existence of hypertrophy with dilatation. Auscultation. There is a loud double murmur heard at the second right interspace. The diastolic murmur which is louder and longer than the systolic, grows fainter towards the end of the diastole, so that there is a short silence between the ending of this murmur and the beginning of the systole. There is no aortic second sound. The murmur is loudly transmitted down the sternum, and can also be followed around the chest to the right axilla. At the second left interspace there is a distinct second sound. At the third left space near the sternum, the systolic murmur is lost, and a feeble first sound makes its appearance. At the third and fourth spaces, towards the apex, the feeble first sound disappears and a faint systolic murmur makes its appearance. The systolic and the diastolic murmurs can be followed around to the left anterior axillary line. At the apex the diastolic murmur is still the louder of the two, and is characterized by a lower pitch and a præsyntolic accentuation. The latter feature is recognizable as far as the left anterior axillary line. The diastolic and præsyntolic murmurs are intensified by exertion, whilst the first sound grows fainter and the mitral systolic murmur disappears. The effects of exertion, and the secondary apex beat should be noted as confirmatory of the views here maintained.

CASE II. D. S., aged thirty-three. Presents himself for treatment for acute dyspnea. He is free from all symptoms of cardiac distress. Inspection shows well-marked cervical and infra-clavicular pulsation. There is no distinct apex beat, but a slight systolic tremor about the nipple. The apex beat is found by palpation to be indistinct, and situated behind the sixth rib in the line of the nipple. Percussion proves the existence of hypertrophy and dilatation of the heart. Auscultation. Diastolic murmur at the aortic cartilage and over the sternum, down to the xiphoid cartilage. The murmur commences with a booming second sound which is equally distinct at the pulmonary and aortic regions. The first sound is very weak and is accompanied at the base, with a short pulmonary artery murmur. Over the body of the heart, and as far as a point two inches beyond the apex, the diastolic murmur becomes higher pitched and presents a distinct præsyntolic accentuation.

CASE III. H. A., aged fifty-eight. The physical signs in this case pointed to an enormous hypertrophy and dilatation of the heart, with dilatation of the arch, and obstructive and regurgitant lesion of the aortic valves. The double aortic murmur was sawing in quality, and could be heard all over the sternum. At the fourth, fifth, and sixth interspaces along the left border of the heart, there was a low-pitched, rumbling murmur, which was recognized by all those who examined the case as distinctly præsyntolic in time.

Post-mortem. The heart weighed twenty-one and one-half ounces. The aorta was dilated. The aortic valves were short and thickened, especially about the

edges. The intercoronary segment presented a button-hole slit, with thick, hard edges, the result of sclerotic changes around a congenital fenestration. The mitral leaflets were opaque, large, and slightly thickened, but evidently competent, non-adherent, and smooth. The mitral orifice admitted the introduction of three fingers. The right heart was much smaller than the left, and its valves were healthy.

There was, in the same ward of the City Hospital, an Italian, thirty-nine years old, with a loud, aortic, regurgitant murmur. Marked cyanosis and intense dyspnoea were prominent features of this case. The heart was moderately enlarged. The pulse was small and irregular. There was a loud, presystolic, churning murmur, circumscribed to the region of the apex. These features were contrasted with the somewhat diffuse character of the murmur heard in the previous case, and a diagnosis of organic mitral stenosis was made. Both the mitral and the aortic lesions were found at the autopsy.

It will be readily admitted that a mitral stenosis, whether organic or dynamic, may increase the obstacles to the circulation. But this must not be considered as invariably deleterious. The safety of an over-distended ventricle must occasionally depend upon this check to the inflow of blood from the auricle. I have observed elsewhere that it may be said of this safety-valve action, as of many other compensatory modifications of the heart's action, "that there is no step tending to cardiac impotency which may not be, at some time, or within certain limits, compensatory and salutary."

But the existence of an obstructive safety-valve action in the heart will be more readily admitted in connection with the pulmonary artery. It is not, however, my intention to dwell much upon this problem, which must be of very difficult solution. I shall pass on to the consideration of some murmurs heard in the pulmonary region, principally with the object of calling attention to their great frequency, and of presenting for discussion the subject of their causation.

Pulmonary systolic murmurs are far more frequent than all other cardiac murmurs put together. I have noted the presence or absence of this murmur in one hundred consecutive individuals. This group consisted of all the patients in my wards at the Charleston City Hospital and in the United States Marine Hospital, together with the applicants to the out-patient department of the Marine Hospital Service. Among the last, besides the ordinary dispensary cases, were included a number of healthy individuals, who applied for a certificate of fitness for sea-duty. Now, I found that sixty-two out of the hundred individuals presented a systolic, pulmonary artery murmur proper, either during tranquil respiration, or during respiratory movements especially designed to produce changes of the blood-pressure in the pulmonary arteries. If account is taken, not only of the pulmonary artery murmurs proper, but also of all the peculiar bruits of cardio-pulmonary rhythm heard about this region, the proportion becomes still greater.

The region of the pulmonary artery has been called the region of romance, says Balfour, "because of the various interpretations which have been given to the murmurs having their position of greatest intensity in that situation." These various interpretations, however, are necessary to account for the variety of murmurs heard in this locality. The anatomical reasons

for the frequency of murmurs in this region are: the proximity of the pulmonary artery to the surface; the thinness of the walls of the bloodvessel; the nature of its surroundings; and finally, and most important of all, the proximity of the main trunk to the capillary distribution. It is particularly this last factor that I propose to discuss, and I shall consider it first in the healthy subject.

I have found that a systolic pulmonary murmur can be developed in the majority of healthy individuals, provided we exclude those who possess very thick chest-walls, and those who are not intelligent enough to modify their manner of breathing, according to directions, during the examination; and I further hold that the said murmur is generally a dynamic, obstructive, valvular murmur. It is produced by the action of changes of blood-pressure in the artery upon the play of the semilunar valves. After reaching a certain degree of pressure, the blood in the pulmonary artery evidently must commence to impede the opening of the semilunar valves. The resultant of the two forces, one propelling and the other impeding the onward flow, must be a slanting position of the valves, and, consequently, a narrowing of the orifice, and the production of a sonorous vein or whirl.

The fact that these obstructive dynamic murmurs are much less frequently developed at the aortic orifice, I consider as confirmatory evidence of the views just expressed. If we take into account the greater power of the left, as compared with the right ventricle, and the wide distribution of the systemic circulation, it will be apparent that the aortic semilunar valves cannot be influenced by changes of systemic arterial tension with the same facility as the pulmonary valves are influenced by changes in the pulmonary circulation. There are, however, cases in which an increase of the general arterial tension is expressed, not alone by the accentuation of the second aortic sound, but also by an aortic systolic murmur. I have heard such a murmur in incipient atheroma and Bright's disease, where there was no marked anæmia; and probably all of us have seen cases in which a post-mortem examination failed to confirm the diagnosis of aortic obstruction made during life.

Returning now to the pulmonary artery murmur, as it is heard during ordinary breathing in the healthy subject, I have to say that it is almost exclusively circumscribed to the expiratory act. I hear at once the objection that it is simply a pressure-murmur resulting from the uncovering of the anterior surface of the heart by the receding lung; but this argument can be easily disposed of, for the murmur is loudest, not at the end, but at the beginning of expiration. It is loudest at the moment in which the change from expansion to contraction of the chest sends a wave of arterial pulmonary pressure back against the valves of the pulmonary artery: in fact, in many cases, the murmur is heard only at this moment; namely, with the first beat that occurs during the expiration. It is at this moment (when the blood is retarded in the right heart and in the large veins, just after the beginning of expiration) that the fall of the respiratory curve of the systemic arterial tension commences.

In order further to develop this murmur, and to show the influence upon it of disturbances of the pulmonary circulation, it is only necessary to arrest the respiration. By so doing, the murmur is often developed when it cannot be found during tranquil breath-

ing. It is better to stop breathing during expiration, and especially at the end of normal expiration. A full expiration makes the murmur louder still, but then it sometimes becomes higher pitched and harsher, suggesting the possibility of pressure upon the artery by the stethoscope, or by the heart itself (Quincke's murmur). At the end of inspiration, it is much more difficult to develop the murmur, for several reasons: First, because it requires a longer arrest of the respiration at this stage to produce engorgement of the main trunk, the capillaries being then in a state of dilatation; second, because a prolonged inspiratory effort is soon accompanied by a noisy hum of the intercostal muscles, which very much obscures all other sounds; and finally, because the interposition of the anterior border of the lung interferes with the transmission of any murmur that may be present. Even against these odds, the murmur is frequently heard in inspiration, if the arrest of breathing is pushed long enough.

The most frequent form of this murmur, as heard in ordinary breathing, consists of a soft, short, systolic bruit, of medium pitch, heard with one or two beats during the expiration. It is often detected only during some excitement of the circulation, as at the beginning of an examination, or when the patient stands.

It is very interesting to watch the changes that may be wrought upon the pulmonary second sound by a prolonged arrest of respiration: first, there will be an accentuation of the sound, then a reduplication, then a murmur, and finally both the murmur and sound will become indistinct. Thus indicating the several stages of intensity of the pulmonary obstruction.

Now, in pathological conditions these different changes may be found as evidences of the pathological alterations, for instance, in mitral and aortic lesions, tuberculosis of the lung, fibroid phthisis, emphysema, asthma, pleurisy, pneumonia, embolism; in all of which conditions the valvular murmur is frequently encountered as a manifestation of the obstruction in the pulmonary circulation. A very significant example is found in a reported case of pulmonary embolism, in which the sudden closing of one of the large pulmonary branches was immediately followed by the development of a systolic murmur in the main trunk.

It is not rare, however, to meet in some of these lung lesions with other species of murmurs. One of these, first described by Quincke, is produced by a retraction of the lung, which causes the pulmonary artery to be pressed by the heart against the sternum during the systole. I have occasionally heard this murmur in cases of tubercular infiltration and adhesions of the left upper lobe; but it must be admitted that the evidences of retraction of the lung are very slight in some of the autopsies of cases published in support of this view. When cases of pregnancy and of pneumonia, are made to do service for this theory, under the supposition that the imperfect pulmonary expansion present in such conditions, must cause an uncovering of the pulmonary artery, I am so far from being convinced that I hold to exactly the opposite opinion, and it is this: That in many cases of collapse or disuse of some portions of the lung, such as we find in pleuritic adhesions, extensive bronchitis, and, above all, in phthisis, there is a compensatory activity of other portions of the lung which may include those that lie near the left border of the heart. As we speak of superior costal and of diaphragmatic

breathing, we may speak, in the present case, of mediastinal breathing. The puerile respiration which is produced in these portions of the lung is interrupted by the cardiac movement simulating thereby a pulmonary artery murmur. It is heard generally with the inspiration, disappears with the arrest of breathing, and covers a broader area than the murmurs of the pulmonary artery proper. It is further a very short, high-pitched sound, which appears to originate very close to the ear, and is frequently mistaken with exo-pericardial friction sounds. A murmur of the same nature is quite common in children and in persons with narrow chests.

Some murmurs heard in the pulmonary region have been supposed by Naunyn and others, to be mitral regurgitant murmurs propagated to the surface by the appendage of the dilated left auricle. I believe that the arguments advanced by Flint<sup>2</sup> against a general acceptance of these views are incontestable. The murmur heard over the pulmonary artery in mitral insufficiency is, as I have endeavored to demonstrate, an obstructive valvular murmur, and it belongs with the accentuated second sound and other evidences of obstruction of the pulmonary circulation. The auricular murmur of Naunyn is, in my experience, exceptional. I have recognized it when the following signs were present: auricular dilatation, a mitral regurgitant apex murmur, and a long systolic murmur of low pitch, having its point of greatest intensity to the left of the pulmonary artery. If influenced by respiration at all, I found the murmur to be louder during inspiration.

It will be readily seen that in all these conditions there is more or less obstruction to the pulmonary circulation, and the presence or absence of the pulmonary valve murmur will depend solely upon the different degrees of power of the right ventricle to overcome the obstruction.

Now, are we not justified in assuming that there is a safety-valve action in this attitude of the pulmonary valves? A safety-valve action, which, together with the leakage in the dilated tricuspid orifice would tend to prevent engorgement of the lung by retarding the blood in the systemic veins where, for a time at least, it is less likely to do harm? This is certainly a difficult problem in mechanics; but I am inclined to think that the form of the valvular sinuses must give the artery, under conditions of pressure, a relative advantage in resisting the propelling force of the right ventricle.

There is still another murmur-like sound mentioned by Gerhardt, that may be heard in this most interesting region. It is commonly met with in excited conditions of the circulation, and is produced as follows: The thud of the cardiac systole is often of the same tone or consonant with the respiratory murmur, the latter thereby receiving a rhythmical intensification from the former, and giving rise to a sound which simulates very closely the murmurs of the artery proper. These murmurs by consonance are generally heard during inspiration, and they, of course, cease with the arrest of respiration. They can also be made to disappear by modifying the tone of the respiratory murmur, which can be done by inducing changes in the laryngeal element of that murmur.

Whatever tendency an anemic state of the blood may have to further the production of sonorous veins,

<sup>2</sup> American Journal of the Medical Sciences, January, 1886.

it must be considered operative also, in the conditions that I have attempted to describe in this paper. But aside from the fact that the influence of the changes of the blood is questionable, I think that there is evidence enough to show that the murmurs of anemia find a sufficient explanation in disturbances of the valvular apparatus.

The fact that some of the cases included in my series of pulmonary obstructive murmur were cases of anemia, does not invalidate the interpretation I have given of them. A considerable proportion of the anemic subjects who present a pulmonary artery murmur will be found to have also a mitral regurgitant murmur. The fact that an obstructive pulmonary murmur, or an accentuated pulmonary second sound is found in such cases is evidence enough to show that the mitral systolic murmur is not simply a ventricular murmur or a modification of the first sound, but is a manifestation of actual bicuspid insufficiency. Functional, mitral and tricuspid insufficiencies are as a matter of fact quite common in anemia, being simply the result of ventricular contraction with a diminished volume of blood. The pulmonary murmur accompanying this insufficiency must be valvular obstructive. The views of Naunyn, already discussed in this paper, in connection with organic mitral murmurs, will be found even less applicable in anemia. For if the transmitted murmur is often absent when we have distinct evidences of auricular dilatation, why should it be present at all when, as in anemia, there is no evidence whatever of such a dilatation?

There is another mechanism by which murmurs are produced, in anemia, throughout the vascular system. We have in anemia a reduction of the volume of blood. The diminished calibre of the circulatory channels without lessening of the stream velocity gives rise to the formation of sonorous whirrs, because the valves require a certain amount of expansion of the vessels in order to apply themselves smoothly to their walls, without giving rise to some obstruction. The normal rhythm of these murmurs shows that they are intensified during the partial collapse of the jugulars; and I have noted in two cases the complete disappearance of the cervical hum, in anemic females, during the general vascular engorgement that is noticeable sometimes before menstruation.

I hold therefore with Duchek that venous hums, and basic murmurs also, are of valvular origin, not as he believed, that the valves themselves are the starting point of sonorous vibrations, but that they act as obstacles to the circulation, and producers of sonorous whirrs.

The valvular theory of venous hums received a decided check in the fact that the murmur was found in cases where the jugular veins proved to be valve-less. But I have no doubt that in such cases the murmur is due to regurgitation into the jugulars. I occasionally see a young sailor who has but slight anemia and who presents on the right side the loudest jugular hum that I have ever heard. It differs from the ordinary anemic murmur in the fact that it grows feebler and may even disappear during inspiration. It is further distinguishable as a murmur, not of diastolic but of pre-systolic intensification (cardiac time). It is loudest, therefore, at the moment of the auricular systole, corresponding with the negative pulse of the veins. I have concluded that there must be in this case some defect of the jugular valves.

## THE TREATMENT OF PHTHISIS BY INHALATION OF ANTISEPTICS THROUGH COMPRESSED AIR-VAPOR. REPORT OF EIGHT CASES.

BY EDWARD O. OTIS, M.D.

At the present time, something more is being attempted in the treatment of phthisis—I do not include climatic treatment—than the old-time opium, cod-liver oil, and lies, accompanied, on the part of the physician, with skepticism and consequent lack of interest, and on the part of the patient, with hopelessness or self-deception as to the final result.

The new methods, first of all, have given the physician a deeper interest, or *some* interest, in his consumptive cases, and more eagerness and hope in their management. Without some ray of hope in the prognosis, the doctor is of little good to his patient, and the visits of a cheery friend will probably produce better results, or, at least, are more to be desired.

The new methods are those of pneumatic differentiation with the cabinet; compressed air-vapor, with antiseptics; gaseous enemata; direct injections of antiseptics into lung cavities, as practised by Dr. White, of New York; and, in some few cases, incision into a lung-abscess and drainage.

During the winter, I have treated eight cases of phthisis with compressed air-vapor and antiseptics at the out-patient department of the Carney Hospital, and although so few to report, still they may afford some reflection as to this method of treatment. The instrument used was one manufactured by Messrs. Codman and Shurtleff, and kindly presented to the hospital.

The inhalations were given every day, or as often as the patients would come, and for about ten minutes at a time. The patients were under treatment from a few weeks to two or three months. Only two formulae were used, those first suggested, I think, by Dr. Evans. They are as follows:

No. 1.	R	Carbolic Acid . . . . .	3 iss-5 ill.
		Borax . . . . .	5 ill.
		Glycerine . . . . .	3 ss.
		Aque distill. ad . . . . .	3 iv.
	M.	Filter.	
No. 2.	R	Co. Tinct. Iodine . . . . .	m 7.
		Tinct. Conium . . . . .	m 15.
		Glycerine . . . . .	3 iv.
		Aque ad. . . . .	3 iv.
	M.		

The patients were taught to take full, deep inspirations, and told to practice this at home and in fresh air. General hygienic rules of living were given, and in nearly all cases, the compound syrup of the hypophites was administered.

CASE I. L. M., thirty-five years, widow. Husband died of phthisis; no family history of tubercular trouble. Has had cough in the morning, only, for four years. Muco-purulent expectoration; loss of strength; shortness of breath.

Physical examination: Dulness of the summit of the chest on the left side, with subcrepitant râles. Tubular respiration in a circumscribed spot at about the third rib. Roughened respiration, with subcrepitant râles at the summit of the right side. A few moist râles at the left base. Weight, 99 pounds.

She was under treatment between two and three months, but not every day. Her weight increased to 101 pounds, and she said she felt stronger and could breathe better. The physical examination, however, indicated no change.

CASE II. J. H., thirty-six years, teamster. Family history not known. Symptoms of pulmonary trouble developed after exposure. Hemoptysis once. Mucopurulent expectoration; dyspnea; loss of strength, flesh, and appetite. Night-sweats at times. Bacilli found in sputa.

Physical examination: Dulness, bronchophony, and moist râles at the summit of the chest, on the right side. Moist râles over the left chest, with dulness. Coarse, dry râles over left front. Weight, 130 pounds.

He was only under treatment about a month, and at the end of that time had gained eight pounds. His appetite had improved, and cough was better. The physical examination was the same as at the beginning.

CASE III. K. C., domestic, about twenty-two years. Family history good. Has not been well for two or three years. Cough for a few weeks only. Hemoptysis; night-sweats; loss of strength and appetite. Mucous expectoration; scanty menstruation.

Physical examination: On the right front, above the level of the third rib, a few fine, moist râles and some squeaks. Examination otherwise negative. Weight, 125 pounds. This patient was very faithful in her attendance, and at the end of about two months the râles had disappeared, and no signs of trouble anywhere were discovered. Her appetite had improved, and she had gained two-and-a-half pounds. There was still, however, a little cough.

CASE IV. J. G., a young man of twenty years. No family history of tubercular trouble. Well, up to a year ago. Hemoptysis; night-sweats; dyspnea; loss of appetite and cough.

Physical examination: Dulness, tubular breathing, bronchophony, and moist râles at the summit of the chest, on the right side. Moist râles and harsh respiration over the left front. He had constant hemoptysis, rapidly failed, and died in nineteen days after he first came to the hospital.

CASE V. N. H., a frail, delicate child of eleven years. Phthisical family history. Hemoptysis; night-sweats; loss of appetite.

Physical examination: Dulness; tubular breathing; moist and dry râles at the upper part of the chest, on the left side. Harsh respiration and a few dry râles on the right side. Weight, 47½ pounds. She was under treatment about a month, and gained a pound-and-a-half. She was then sent to the Children's Hospital, where she could have better care than it was possible for her to have at home; and besides, the risk was great in coming to the hospital during the inclement winter weather.

CASE VI. A. M., a young woman of twenty years, of good family antecedents. The trouble is of about a year's standing. Cough; purulent expectoration; chills; occasional night-sweats; dyspnea.

Physical examination: Dulness over the front of the chest, most marked on the left. Dry râles on the left front; rough respiration on the upper right front, and a few moist râles over the corresponding portion of the back. Weight, 119 pounds.

After about a month's treatment, there seemed to be some slight improvement. No chills or night-sweats.

CASE VII. C. L., a young woman of eighteen years. Mother died of phthisis. Her trouble began about two years ago. Hemoptysis; night-sweats; temperature 101.5°, pulse 116.

Physical examination: At the summit of the chest, on the left side, dulness and abundant moist râles.

Weight, 120 pounds. No improvement followed the use of the inhalations. The acute symptoms persisted, and at the last report her weight had fallen to 115 pounds. Antipyrine was given for the fever.

CASE VIII. E. W., a man of fifty-two years, with a good family history. His present trouble began about six months ago, when he began to lose flesh and strength. Now has cough, mucopurulent expectoration, occasional night-sweats.

Physical examination: Lack of resonance at the left apex, with abundant moist râles. Weight, 130 pounds.

About a month later, his weight had increased to 137½ pounds, and there were but a few moist râles at the left apex. His appearance was much improved.

Several other patients began with the treatment, but did not follow it up long enough to make it worth while to report them.

So far as one can draw any conclusions from these few cases, they would be these: in advanced cases of phthisis there was no essential improvement, but sometimes an amelioration of some of the symptoms; in beginning cases, there seemed to be some real improvement.

From the necessities of out-patient practice, the inhalations could be given but once a day, and then for too short a time. I am of the opinion that in order to obtain the best results from this method of treatment, the inhalations should be given two or three times a day, and from fifteen to twenty minutes at a time.

Certain it is that the patient learns to breathe more properly, and to take deeper and fuller inspirations, which, in itself is of no small importance. Indeed, I think much pains should be taken in teaching the consumptive how to expand his lungs fully—that which many well people do not understand. Light, free, hand-gymnastics, such as is taught in the gymnasiums now, are calculated to expand the chest, seem to me to be an important auxiliary to other treatment. It is a good thing to place the patient against the wall, straighten up the shoulders, and to teach them to keep them thrown back in walking, which enables them to take fuller and deeper inspirations. Walking with the palms of the hands turned out, as one sees the cadets do at West Point, is also a capital device for keeping the shoulders back.

If this form of treatment is likely to be used in any case for a long time, as it should be if any pronounced results are to be obtained, it would be better to have a large reservoir for the compressed air; the constant pumping is tiresome and annoying.

As to the antiseptics used, I suspect that it does not make so much difference what they are. Of the two used in these cases, I could not see much difference in the results; the carbolic acid one seemed to be more irritating than the iodine. This method would seem to offer enough to warrant further trial.

—The recent serious and nearly fatal illness of Prof. Billroth, from which he is now, however, happily convalescent, consisted at first in a sharp attack of bronchitis which confined him to his bed. Then acute pneumonia supervened. These conditions, combined with fatty degeneration of the heart, brought about a state of alarming prostration. He appears to have derived most benefit from inhalations of pure oxygen, which were prepared for him every day.

## Clinical Memorandum.

### A CASE OF BERI-BERI.

BY H. J. POMROY, M.D., OF BROOKLYN, N. Y.

As the attention of the readers of the JOURNAL has been called to cases of beri-beri quite frequently of late, perhaps the following history of a case might prove of interest:

D. K. P., an American, fifty-three years of age, has followed the sea since boyhood. While in command of a barque, he visited many foreign ports, and, consequently, many different climates. During the last few years he has resided, and has been engaged in mercantile pursuits, in the city of Para, Brazil. He had always enjoyed good health until a few months before his departure from Para, in the spring of 1885. His present illness began with swelling of the feet, gradually extending upwards to the thigh, scrotum, and abdomen. As the swelling increased, his appetite and strength diminished. He had no pain. Slight numbness in the lower extremities, especially below the knees. Finally, dyspnea, slight cough, with scanty expectoration. No dimness of vision or nausea. Bowels constipated. From the first, the patient recognized the disease as beri-beri. Having seen and heard of persons similarly affected, and being aware of the fatality of the cases which had reached the stage of effusion into the thoracic and abdominal cavities, he decided to take the only known measure of relief, namely, change of climate. When only a few days out from Para, bound to New York, he experienced great relief from dyspnea, and with an increase in the daily amount of urine, his oedema subsided. I did not see him until two weeks after his arrival in New York. There was no apparent anemia. He was, on the contrary, decidedly plethoric. There was no ascites at this time. The heart, lungs, and liver were normal. The specific gravity of urine was 1015. The amount in twenty-four hours, 1800 cc. Normal color and reaction; no albumen. Microscopical examination revealed nothing abnormal. There was oedema of the legs below the knees, the skin pitting on pressure. The patella reflexes were much diminished. No tenderness anywhere. Muscles, to the touch, appeared normal, and their electrical reaction was normal.

The patient sailed for Liverpool six weeks after his arrival in New York, to all appearances well. He had no medicinal treatment after leaving Para. Subsequently, on returning to Para, three months later, his friends expressed great surprise on seeing him alive and well. The patient says that in all probability, following the usual course in cases of beri-beri, he will have a return of the disease, and will be obliged to leave the country permanently. In his last letter, received some two months since, he stated that he was still in good health.

— According to the *British Medical Journal*, on June 9th, Mr. Victor Horsley removed a tumor in the dorsal region of the spinal cord from a patient under the care of Dr. Percy Kidd. The patient had been seen by Dr. Gowers, who diagnosed a localised neoplasm, and suggested operative interference. The tumor measured about one inch and a quarter by half an inch. The wound is now practically healed.

## Reports of Societies.

### MASSACHUSETTS MEDICAL SOCIETY.

#### COUNCILLORS' MEETING.

The annual meeting of the Council was held at the Medical Library, Boston, on the evening of Tuesday, June 7, 1887. One hundred and thirteen Councillors were present. The meeting was called to order by PRESIDENT GAGE, at seven o'clock.

The Secretary announced the names of ninety-seven Fellows who had been admitted during the year, and of twenty-seven who had died.

#### FINANCES.

The Treasurer's report showed the year's receipts—including a balance of \$1,767.37 from the previous year's accounts—to be \$10,516.21. The disbursements amounted to \$8,201.00, leaving a balance of \$2,315.21. The invested funds of the Society amount, as in the previous year, to \$32,420.17. The Society now bears upon its catalogue the names of 1,651 members.

The report further stated that assessment dues to the amount of \$55.00 have been remitted by vote of the Councillors, upon the recommendation of the Committee on Membership and Finances. Twelve members of the Society have lost their membership by removal from the State, and neglect of their assessment obligations. Since the last annual meeting the names of four Fellows have been dropped from the roll, with the approval of the Council, in accordance with the By-Laws, for five years' delinquency in assessments.

In accordance with the recommendation of the same Committee on Membership and Finances, reporting through Dr. Minot, it was voted that \$1,000.00 of the balance remaining in the treasury be distributed among the District Societies.

On recommendation of the Committee, dues were remitted to several Fellows, others were dropped from the roll for non-payment of dues, others were allowed to resign, and still others were permitted to become retired members.

DR. SHATTUCK reported for the Committee on Publications, and reminded the Councillors that at the Annual Meeting of the Society in 1888, the name of the successful candidate for the Shattuck prize of \$1,000.00, if such there be, would be announced.

DR. WHITE read the report of the Committee on the By-Laws of the District Societies, and the Librarian, Dr. Brigham, presented his annual report.

#### ELECTION OF OFFICERS.

The Committee on Nominations reported the following list of candidates for the offices of the Society for the ensuing year, and the same were elected by ballot: Dr. Thomas H. Gage, of Worcester, President; Dr. William G. Breck, of Springfield, Vice-President; Dr. Frank W. Draper, of Boston, Treasurer; Dr. Charles W. Swan, of Boston, Corresponding Secretary; Dr. Francis W. Goss, of Roxbury, Recording Secretary; Dr. Edwin H. Brigham, of Boston, Librarian.

On the announcement of the result of the ballot, the President thanked the Councillors for the renewed expression of their confidence and esteem.

## THE NEXT MEETING.

It was voted that the next annual meeting of the Society be held in Boston, on the second Wednesday of June, 1888.

Dr. B. Joy Jeffries, of Boston was chosen Orator and Dr. Charles B. Porter, of Boston, Anniversary Chairman for that meeting.

## APPOINTMENT OF COMMITTEES.

The President nominated, and the following were appointed to constitute the standing committee:

Of Arrangements.—J. B. Swift, H. C. Ernst, W. W. Gannett, O. K. Newell, V. Y. Bowditch, F. B. Harrington.

On Publications.—G. C. Shattuck, R. M. Hodges, B. E. Cotting.

On Membership and Finances.—F. Minot, B. S. Shaw, D. W. Cheever, J. Stedman, E. G. Cutler.

To Procure Scientific Papers.—C. W. Swan, G. S. Stebbins, J. R. Chadwick, R. H. Fitz, H. P. Walcott.

On Ethics and Discipline.—G. J. Townsend, G. E. Francis, A. H. Johnson, C. Howe, F. C. Shattuck.

On Medical Diplomas.—W. L. Richardson, A. H. Cowdrey, E. J. Forster.

## CONNECTICUT STATE MEDICAL SOCIETY.

The ninety-sixth annual convention of the Connecticut Medical Society was held May 25th and 26th, at Hartford, in the County Court House. This place of assembling (Superior Court Room) was the same as that of two years ago, when it gave universal satisfaction by reason of its airiness and lightness, and freedom from disturbing noises.

The first gathering, at 3 P. M., was the meeting of the Fellows, or Executive Council of the Society, and at least forty out of the full number of fifty-three were present. The exercises opened with the President's address to the Fellows, by Dr. T. M. Hills, of Williamantic, which was very brief. The principal recommendation was that the discussion of the "Proposed New Charter Question" should be considered closed, having already occupied the greater part of the time of one special and two regular meetings, and having been voted down at the last annual meeting by the decisive vote of 25 to 8. He noted the similarity between the organizations of the Connecticut and the Massachusetts Medical Societies, and thought the success of the Massachusetts Society showed that the organization was not at fault for any lack of interest. He also advised that a standing committee be appointed to watch the legislative enactments that, from time to time, might be brought before the State Legislature, which had a bearing on the practice of medicine, or upon the interests of the medical profession, and report to the Society such proposed enactments, with suggestions for action on the part of the Society.

A committee of three was appointed to consider the suggestions of the President in his address, and report to the next convention.

Several resolutions were then read by the Secretary, which had been received from various county societies. Three counties desired that the subject of any change at all might be dropped, and time allowed for other matters. One desired some change, but did not express any preference, except to say that it would be desirable to conform as nearly as might be to the

form of the Massachusetts Medical Society. One wished an increased representation in the body of Fellows; namely, five for the first twenty-five members in the county society, and one for each additional twenty-five members, making more nearly a *pro rata* representation, such as exists in Massachusetts, and thus being in effect nearly what the preceding society asked for. One society wished a revision of the Charter, essentially as called for by the proposed new charter, which was voted down last year.

These resolutions were referred to the Committee on County resolves.

A committee appointed last year to confer with committees from the homoeopathic and eclectic societies, in reference to some practical action looking to the adoption of some such Act as that proposed by the American Medical Association to insure proper qualification among those practising medicine, then made a report that they had held conferences with committees from the other societies, and had drafted an Act, which was presented to the Legislature, but at so late a day in the session, that it was found impracticable to carry it through to final action, and it was laid over to the next session.

The Secretary laid before the meeting the circular of Dr. Dunglison, of the International Medical Congress Financial Committee, calling for pecuniary aid from the State medical societies. Subsequently, the Treasurer's report having shown that there was barely sufficient money in the treasury to pay the current expenses of the Society for the ensuing year, a committee was appointed, of one from each county, to solicit subscriptions in aid of the Congress.

The Committee on Honorary Members and Degrees recommended that Prof. J. C. Dalton be made an Honorary Member. Under the rule, this recommendation lays over, to be acted upon next year.

The Nominating Committee reported the following list of officers, who were all elected: President, Dr. Francis Bacon, New Haven; Vice-President, Dr. George L. Porter, Bridgeport; Treasurer, Dr. E. P. Swasey, New Britain; Secretary, Dr. S. B. St. John, Hartford.

The Committee on County Resolves reported, favoring no action in the matter of amending the Charter. The report was not accepted, and after considerable discussion, in which the question of increased representation was considered, it was voted to appoint a committee of two from each county to consider the question of amending the Charter, and report at the next convention, with the draft of an Act, if thought best to make any change. Thus the question which has kept the executive meetings in a ferment for three years is to be upon the carpet for another year, at least.

The Society adjourned, to meet in special session at 7.30 P. M., to listen to a paper on

## ULCERATION OF THE OS UTERI,

by DR. E. W. CUSHING, of Boston, who had been specially invited by the Society to address the convention. The paper was a very interesting one, and was listened to with marked attention. While free from any attempt to display great erudition, it was full of suggestions that the author was thoroughly at home in the literature of the subject, and the illustrations, many of which were microphotographs, made by Dr. Cushing, and Dr. Parker, of Lowell, who was present, and kindly assisted in

showing them by means of a stereopticon, showed that the recent theories regarding the part taken by the glands of the cervix in these so-called ulcerative processes have a substantial basis of fact. The micro-photographs showed that, in many cases where there seemed to be great loss of substance, the layer of cylindrical epithelium was still intact, and so long as this was the case, it was held that true ulceration had not taken place. In other instances this line of cylindrical epithelium was absent, as in the case of carcinomatous and tuberculous ulceration. The condition known as erosion is rather an active formation of glandular tissue.

In the discussion which followed, Dr. CARMALT said he considered Dr. Cushing's micro-photographs clearly demonstrated the transition of adenoma into carcinoma, and thereby confirmed the views he had held and taught for many years. It also demonstrated the correctness of the Thiersch and Waldeyer theory of the epithelial origin of carcinoma—a theory which is constantly receiving confirmation by investigations in various fields of surgery and pathology. It follows from this paper that, in operating, the incisions must be made deep enough to remove all the glandular new growth. The paper was further discussed by Drs. Storrs, Avery, and Ingalls.

The annual convention of the full Society assembled at 9.45. The Secretary's report showed eight deaths during the year, among them one of the ex-Presidents, Dr. Carleton, of Norwich, a Harvard graduate. Seven removals and eight resignations or expulsions were offset by new members, to the number of twenty-eight, leaving a net gain of five members, and a total membership of five hundred and five. The new members are in about equal proportions from Yale Medical School, University of New York, and College of Physicians and Surgeons of New York, Harvard sending only one.

Only one delegate reported from sister societies, Dr. TAYLOR, from New Jersey.

Dr. A. E. ABRAMS, of Collinsville, read a dissertation upon

#### THE TREATMENT OF DISEASES OF THE EAR BY THE GENERAL PRACTITIONER.

He dwelt at length upon the harm done in considering an earache or an otorrhea as of secondary importance, or as something for which very little could or need be done, and found, in the prevalence of this opinion, the reason for the existence of so much chronic ear disease as we are constantly meeting with. He urged the seriousness of even the simpler forms of children's ear troubles, and held that they should always be given close attention, while in those accompanying the exanthemata, the treatment should be even more carefully insisted upon. The use of leeches, hot water, and careful cleansing of the ear when discharge was present, was dwelt upon. The reader espoused the dry treatment method so far as applications go, though he advocated using the syringe for cleansing purposes. He found that his suppurative ear cases did better under the use of boracic acid than almost anything else.

Dr. CARMALT emphasized Dr. Abrams' remarks as to the importance of early attention, saying that physicians too often agreed with the parents that it was not necessary to pay much attention to a running ear.

Dr. ST. JOHN noted that a persistently running ear was not regarded without suspicion by the Life Insur-

ance Companies who viewed this matter from a business standpoint, and whose opinions were based on statistics from a large number of cases. They had discovered that a certain percentage upon their death-lists showed upon examining the detailed record that there was a history of persistent otorrhea, and the death was ascribed to meningitis, abscess of brain, or other head affection which might reasonably be joined to the ear trouble in the relation of cause and effect. He also, in speaking of the treatment, said that he could not get uniform success by using boracic acid or any other powder, and while he used boracic acid a great deal and regarded it as almost invaluable, yet he believed it applicable only to those cases in which a large opening existed in the membrana tympani through which the powder could easily make its way into the tympanic cavity. In a large class of cases in which the perforation was small, he had been much disappointed in its use, and notably in those obstinate cases in which the opening is in Schrapnell's membrane. In these cases he still relied on the use of thorough cleansing by the syringe, especially by the "middle ear syringe" and the use of astringent remedies.

The Committee on Matters of Professional Interests reported that they had sent a circular letter to many members, asking answers to various questions. The circular asked "the usual fees and mileage for medical attendance," "the fees for obstetrical cases, complicated and uncomplicated," and "proportion attended by unqualified midwives"; also the "proportion of death certificates returned by persons not graduates from recognized medical schools (regular homoeopathic and eclectic)"; medico-legal cases were also asked for. The questions in the circular were prompted by the introduction into the Legislature of the bill before referred to. The Report of the Committee says: The answers show

*First*, that visits throughout the State are 75 cents to \$3.00, mileage 25 cents to \$1.00. Office fee 50 cents to \$2.00. Obstetrical fee \$5.00 to \$25.00 for ordinary cases. In county towns with low fees, nearly all obstetric cases are attended by regular physicians. In cities with large fees unqualified midwives thrive and grow fat. In the cities they attend about one-third of the births. The committee suggested lowering the fee in cities so as to drive out the ignorant midwives. If this were not done, we should advocate schools for the better training of midwives.

The Report was accompanied by an account of three cases in which the ignorance of the midwife was undoubtedly the cause of the woman's death.

Dr. G. R. SHEPHERD, of Hartford, read a paper on

#### CLIMACTERIC GLYCOSURIA,

giving the histories of four cases he had noted, and adding an exhaustive review of the literature of the subject. He found these cases are not like ordinary glycosuria, in that there is not any marked thirst or emaciation. One case showed obstinate pruritus vulvar as the prominent symptom, which disappeared spontaneously, as did also the sugar in the urine three years later. The second and third cases were almost counterparts of this, and in all, the establishment of diabetic regimen had little or no effect upon the amount of sugar in the urine.

The fourth case complained chiefly of pruritus vulvar, and examination showed between the swollen labia a considerable deposit of whitish material, which the

microscope proved to be identical with sugar fungus, and a large amount of sugar was found in the urine. The special features in these cases were noted, as glycosuria appearing in women at or near the climacteric period, accompanied by but one symptom calculated to attract attention, namely, pruritus vulvar of chronic and obstinate form, the disease continuing several years without detriment to the general health, and subsiding spontaneously, apparently uninfluenced by treatment.

A paper on the

#### RELATIONS BETWEEN SCROFULA AND TUBERCULOSIS,

by DR. KENT, of Putnam, was an earnest attempt to establish some order in what is apt to be regarded as a chaotic subject, and though laying no claim to originality, it showed extensive and intelligent reading. His conclusions were (1) that manifestations of scrofula are commonly associated with tubercle, either fully formed or embryonic; (2) the form of tubercle met with in so-called scrofulous diseases is usually of elementary character; (3) scrofula, therefore, indicates a milder form or stage of tuberculosis, and the two processes are separated simply by degree.

In a paper on

#### NEW REMEDIES,

DR. RUSSELL dwelt upon antipyrine, thallin, kairin, antifebrin, paraldehyde, and cocaine. Antipyrine was specially recommended in typhoid fever, pneumonia, and tuberculosis. He thought it a "prompt, reliable and powerful antipyretic." Thallin is less known, and perhaps not so effective. Kairin is more likely to cause collapse. Antifebrin is four times as powerful as antipyrine, and deserves further trial. Paraldehyde produces in fifty m. doses quiet dreamless sleep, possibly preceded by a stage of excitement: it appears to be superior to chloral in nervous insomnia, especially in that from over-use of alcohol. It may be well given as enema with yolk of egg and infusion of marsh mallow, and should not be used hypodermically. In the discussion a case was given in which the insomnia resulting from withdrawal of morphine in an opium-eater, was overcome at once by paraldehyde.

The Society then adjourned to the annual dinner.

#### THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting May 5, 1887.

DR. N. M. SHAFFER read a paper, prepared by himself and DR. R. W. LOVETT, of Boston, on

#### THE ULTIMATE RESULTS OF THE MECHANICAL TREATMENT OF HIP-JOINT DISEASE; AN ANALYSIS OF FIFTY-ONE CASES OCCURRING IN THE SERVICE OF THE NEW YORK ORTHOPÆDIC DISPENSARY AND HOSPITAL.

All the cases were in dispensary patients, and all cases of excision were excluded. The difficulties met with in successfully carrying out a course of treatment among this class of patients in any chronic trouble, he said, were especially marked in the case of such affections as hip-joint disease, where the treatment was a matter of years, and also involved the use of mechanical apparatus. In order that satisfactory results could be obtained in such cases it was requisite that the dispensary should be fully equipped with suitable appli-

ances, and that the attending surgeons should have the co-operation of a competent and energetic out-door surgeon. The home-treatment entered largely into the result, and in a certain proportion of the cases, owing to the peculiar circumstances of the patient, hospital treatment would be necessary.

The results given in the paper were recorded by Dr. Lovett, and the following were among the points fixed upon as the bases of the investigation:

No case was considered which had not been treated exclusively in the service of the Orthopædic Dispensary.

No case was considered which had not been discharged cured.

No case was considered which had not been cured for at least four years.

No case was considered which had not been under treatment for at least two years.

All the cases which came under these exclusive conditions were included in the report. The period considered was the five years from 1877 to 1882, and during this period there were treated altogether 778 cases of hip-joint disease at the institution. Of these, 168 cases, or over 21 per cent. were discharged cured, 261 discharged relieved, 49 discharged for neglect of orders, and 6 discharged as incurable; while 64, or between 6 and 7 per cent. died. Of the deaths, 20 were due to tubercular meningitis, 5 to amyloid degeneration of the kidneys or other organs, and 3 to phthisis. It was the practice to discharge patients *experimentally* cured; watching the effect of leaving off the apparatus for a time. In some of these it was necessary to resume the mechanical treatment for a longer or shorter period before they could be discharged permanently cured.

The plan of treatment adopted in all cases was to apply the long Taylor splint, and instruct the parents or friends in its use. Unless the recumbent posture were required by the special circumstances of the case, the patient was allowed almost unlimited exercise in the open air, and once a week it was expected that the child should be brought to the dispensary for examination. The aims of the treatment were: (1) To overcome by mechanical means any existing deformity. (2) To protect the affected parts from traumatism. (3) To secure free out-door exercise. (4) To maintain that position of the limb in which, in case ankylosis should result, there might be the least amount of deformity.

No operations were performed, with the exception of occasionally evacuating an abscess, and little medication was resorted to. Much credit, Dr. Shaffer thought, was due to the efficient assistant surgeons of the institution for their faithful devotion to the cases. The long splint used was made without any joint at the knee. He thought the results would probably have been even better than they were if an intermediate apparatus had been employed, as was usually done in private cases; but on account of the additional expense involved, the institution was unable to provide this.

Of the fifty-one cases on which the paper was based, four were ascertained to have died. Two of the deaths were due to tubercular meningitis, and the other two to acute pneumonia; the latter patients having been in good health up to the time of the attack which carried them off. Of the remaining forty-seven, six had relapses. One of these patients remained well two

years, two, three years, two, four years, and one five years; and in one of these cases the relapse was due to a fall from a cart. In one of the cases excision of the hip had been performed, and the patient, at the end of a year, was still in bed. In the other five the treatment by traction had been resumed, and of those, two were cured a second time, two were now nearly well, and one was slowly improving.

Passing on to speak of the difference in the length of the two lower extremities. Dr. Shaffer said that the amount of shortening did not seem to depend on the presence or absence of abscesses; although there was a larger proportion of cases of shortening with abscess than of those without. The influence of age on the amount of shortening was quite marked; the greatest amount of shortening occurring in late cases, that is, when the patients were over ten years old when the trouble commenced. It was a fact worthy of note that the difference in the length of the limbs almost always increased slightly after the case had been discharged cured. As to the difference in the circumference of the two thighs, in the majority of instances it was between one and two inches; and when the result was most perfect this was never less than one inch. No relation was observed between the amount of shortening and that of atrophy. The atrophy of the calf was more marked than that of the thigh in after years. A study of these cases seemed to show beyond a doubt that the muscular growth of the limb received a shock from the occurrence of hip-joint disease from which it never afterwards fully recovered. The atrophy might doubtless have been diminished by massage and other appropriate treatment; but in dispensary practice it was not practicable to carry such a course of treatment out.

In nineteen of the cases recovery took place with ankylosis. Three of the patients had perfectly free motion in every direction. The presence or absence of abscess seemed to have little influence on motion. An investigation of these cases showed that the amount of motion, as a rule, grows less, instead of greater, as time goes on; and in no case did the motion increase after the discharge of the patient. A careful examination was made in regard to the presence of lateral curvature of the spine, and it was found that in only one out of forty cases was there anything at all approaching true rotary lateral curvature. In this case, however, the latter condition was not really present. It was found that after cure the limb on the diseased side does not grow as rapidly as the unaffected one, and Dr. Shaffer thought this was no doubt the reason why the difference between the length of the two limbs so often became greater as time went on. In case of ankylosis, adduction, rather than flexion, was the thing to be most avoided.

In conclusion, he stated that these cases showed that conservative methods of treatment gave better results than ex-section. Excluding the four cases which died and the six which relapsed, there was not a single individual among the patients who were incapacitated for pursuing a useful avocation.

Dr. Lovett stated that as a part of the work included in the present investigation, he had visited and examined three patients at their homes, and he had found that, taken altogether, they were an exceptionally healthy set of people. There were only four who were not in robust health. One of these was a boy, who was the only one of the number who used a

crutch or cane; and the other three were young women who, while anæmic and inclined to be delicate, presented no signs of tuberculosis. There were very few who wore high soles on the affected side; although quite a number had tried this for a time, but found that they could get along better without this device. As had been remarked, adduction was the unfortunate deformity resulting from hip-joint disease. It made the gait ungainly, gave rise to pain in the back, and rendered the practical shortening of the limb a good deal in excess of the actual bone shortening. Nearly half of all the cases complained of more or less pain in the affected limb during damp weather; but in not a single instance was there the slightest reason to suspect any return of the disease.

Dr. J. F. RIDLON said that by this paper the claim was substantiated that hip-joint cases could be successfully treated in dispensary practice. Having been for six years connected with the Orthopedic Dispensary, three of which were spent in the out-door department, he was very familiar with such cases as those described. It seemed to be assumed by Dr. Shaffer that all the cases were of tuberculous nature; but personally he believed that many cases which were supposed to be of strumous origin were in reality due to traumatism. He also thought that a considerable proportion were due to inherited syphilis. It therefore seemed reasonable that the causation of the trouble should modify the treatment adopted, to a considerable extent. In traumatic cases, where there was more or less dead bone present, he thought it was good surgery to cut down and remove it. If such cases were allowed to go on without operation, they were very apt to end fatally; while in instances of this kind where even a very large fragment of dead bone was removed, he had seen the patients make a perfect recovery. If a diagnosis of inherited syphilis were made, antisyphilitic treatment should be employed, in addition to the usual splint. He had, indeed, seen one or two syphilitic cases get well under antisyphilitic treatment, without the use of mechanical means at all. He was convinced that many cases which were supposed by orthopedic surgeons to be of tuberculous character were in reality syphilitic, and he knew of one case of this kind which was treated with simply a hip-splint for two years, when a syphilitic eruption appeared. As to whether there was any way of deciding whether a case was tuberculous or syphilitic, he thought, was a matter worthy of investigation; and it seemed to him that it was advisable to try the effect of internal remedies in addition to mechanical treatment.

Dr. S. KETCH said that he thought Dr. Ridlon was mistaken in the statement that it was assumed at the Orthopedic Dispensary that all cases, without exception, were of tuberculous origin. It was also a fact that quite a number of cases, in addition to mechanical appliances, were treated with such remedies as iron, cod-liver oil and the hypophosphites. His personal experience with the mechanical apparatus employed led him to consider that with it we had a most satisfactory method of treating hip-joint disease. Not only were good limbs secured, but also relief from suffering; and many of the cases were saved from the knife.

Dr. LEWIS A. SAYRE said that the conclusions of Dr. Shaffer corresponded to a great extent with the views which he had been teaching for the last thirty years. If proper mechanical treatment was carried out, the patient usually recovered. Whether there

was a predisposition to tuberculosis, syphilis or other dyscrasia or not, he had observed that in almost all cases an exciting cause, however trifling, had been required to develop the trouble in the hip-joint, this traumatic influence serving to fix the pathological process at this particular point. If any hereditary taint were present, of course a very slight injury was required for the development of the disease. With appropriate mechanical treatment and the use, in suitable cases, of such measures as blisters, leeches and the hot iron, a fair result could usually be obtained; and there were scores of his patients in this city and elsewhere who now had perfect motion in the limb. Many of these he had seen in consultation with such surgeons as Mott, Willard Parker, Van Buren and Hamilton; and the results were so successful that it would never be suspected that they had ever had hip-joint disease at all.

If we could succeed in arresting the disease, Dr. Sayre went on to say, mechanical treatment was all that was required. But in spite of suitable mechanical means and the internal use of cod-liver oil, bi-chloride of mercury, or other remedies that seemed to be indicated, there were a certain number of cases which, instead of improving as time went on, only kept growing worse. If, therefore, caries went on increasing, with long continued suppuration, which was liable to result in amyloid degeneration, then the knife was the proper thing to resort to. Instead of letting a case go on for eight years, as had been done in some of those reported in the paper, with the health becoming all the time more and more impaired, he thought excision was infinitely preferable. So far as results were concerned, these would be incomparably better than in serious cases of this kind in which it was not resorted to. In this connection he referred to two patients in whom he had performed excision, one of whom afterwards became a champion foot-ball player and college athlete, while the other had earned a pair of silver skates for his agility on the ice. Yet these are cases in which he believed death would have resulted if he had not performed the operation.

For a number of years Dr. Sayre said he had only been allowed to do excisions in those who were already condemned to die, so strong was professional opinion against the procedure; and, consequently, his statistics were not as favorable as they would have been if he could have selected his cases. A certain number of cases had been referred to this evening as incurable; but he thought it was a great mistake not to give them the chance which excision afforded. Of the seventy cases in which he had performed the operation, many were of this apparently hopeless character. As regards the condition of the spine in the subjects of hip-joint disease, while there might not be present true rotary lateral curvature, it was undoubtedly true that there was more or less lateral distortion in many of the cases.

Dr. V. P. GIBNEY considered the statistics presented in the paper a valuable addition to surgical literature, and particularly as regards the questions of ultimate motion and ultimate atrophy. It would seem from them that the common impression that motion increases, and atrophy diminishes as time goes on was an erroneous one. These were very important points, and they would serve to help us in our prognosis. Personally he had gained increasing confidence in the value of mechanical treatment. With it there were

no exacerbations, there was immunity from suffering, and the children grew hearty and robust.

Dr. A. B. JUDSON said that the limb would take the position that was most convenient to the patient. Adduction was particularly undesirable, and he thought that patients should be drilled so as to spend as much time as possible with their weight on the affected limb.

Dr. L. H. SAYRE said that as long as the patient showed improvement, however slow, mechanical treatment should be persevered in; but when, instead of improving, he steadily lost ground, he believed it was the best plan to remove the dead bone at once. He did not believe, however, in early excisions, and did not think the results thus obtained would at all compare with those of mechanical treatment.

Dr. SHAFER, in closing the discussion, stated that he did not wish to be at all dogmatic in his views in regard to tuberculosis and syphilis. The only way that he could distinguish between the two was by the test of treatment, some cases getting well under anti-syphilitic remedies, and some not. In the early stages, he did not think we could make the distinction. It was important to remember that the paper was devoted exclusively to the results of mechanical treatment among dispensary patients, and he thought that these had unquestionably demonstrated the fact that one adequately equipped dispensary could do the work of three or four hospitals among this class of patients, and at a far less expense. In regard to medicines, the Orthopaedic Dispensary, on account of the large expenditures which it had to make for mechanical appliances, was not able to furnish these. In private practice, however, he was in the habit of using internal remedies whenever they seemed to be indicated.

He did not wish to bring up the question of mechanical treatment *versus* excision. The cases which were spoken of as incurable were those which were incurable as regards deformity, and not the disease itself. Patients with chronic suppuration and sinuses were not given up at all, but followed up until they died; and, in private practice, some of his best results had been in cases of this kind. If he could have the entire control of the child, the parents could be induced to give it the benefit of fresh country air and other needed hygienic conditions, a good result could almost invariably be obtained, provided amyloid degeneration did not occur. In his experience, there were fewer deaths and better general results from mechanical treatment, with this special oversight on the part of the surgeon, than from excision. In the patients which had been referred to in the paper as being eight years under treatment, the eight years were spent, not in combating sinuses, but in getting the best ultimate position and most serviceable limb. These were mostly cases of dry caries. He was not opposed to excision, but he believed that it should be resorted to but rarely. In cases of which he had the entire control, it was seldom or never necessary.

— The Health Committee in the canton of Vaud, Switzerland, has prohibited any public performances of hypnotism, magnetism, or somnambulism. Even medical and scientific men must obtain permission before being allowed to make scientific experiments on those subjects. The reports of recent experiments made in France, would seem to show that such restrictions were not uncalled for.

ASSOCIATION OF AMERICAN PHYSICIANS.<sup>1</sup>

## SECOND ANNUAL MEETING.

## ATROPHY OF THE GASTRIC TUBULES: ITS RELATION TO PERNICIOUS ANEMIA.

by DR. F. P. KINNICUTT, of New York.

The speaker gave the histories of two cases, in which the typical symptoms of pernicious anemia were well marked. At the autopsy in each of these cases, nothing special was found in any organ but the stomach. The inner surface of the organ was smooth. Microscopical examination was made of numerous sections removed from different parts of the stomach. Throughout a large extent, no trace of gastric tubules was found. In some parts, the more superficial portions of the tubules could be found, but the deeper portions could nowhere be made out. There was also seen a peculiar hyaline substance, in the shape of tubes and of drops. Numerous irregular cells were seen near the surface of the mucosa. The author thought that, in this lesion of the stomach, was to be found the explanation of a certain number of cases of pernicious anemia.

## AFTERNOON SESSION.

## DISCUSSION OF DR. KINNICUTT'S PAPER.

DR. FRANCIS DELAFIELD, of New York. In these cases of pernicious anemia, it is natural to look for some influences which would affect the general nutrition. In a number of cases, marked changes in the mucous membrane of the stomach have been found. The main question is, whether the lesion of the stomach is to be looked upon as a cause or as the result of the pernicious anemia. For myself, I look upon the lesion of the stomach as secondary, and not primary. If we attribute the anemic condition to the lesion of the stomach, the condition must be due to a form of starvation. In many other diseases leading to starvation, we do not find the symptoms of pernicious anemia developed.

DR. F. P. HENRY, of Philadelphia. The cases reported by the author, taken in connection with other cases which have been recorded, demonstrate that there is a form of anemia associated with, and, I think, dependent upon, atrophy of the gastric tubules. That this condition is primary, and not secondary, is, I think, sufficiently attested by the fact that it is not found in any other condition. Such an extreme degree of atrophy has not been found in any other condition with which I am acquainted. In the case reported by Dr. Osler and myself, there was complete absence of the peptic glands. It was impossible that any form of gastric digestion could be accomplished. In cases of starvation there is a capacity for digesting food, and in these cases, I think that the condition of the blood which we consider pathognomonic of pernicious anemia does not exist.

DR. WILLIAM OSLER, of Philadelphia. There is unquestionably a group of cases of pernicious anemia in which there are serious lesions of the gastric mucous membrane, although these lesions are not always the same. I think that it is quite impossible to distinguish clinically the cases with gastric atrophy from the cases without these lesions. In a case of two years' standing, although the symptoms were marked, the autopsy revealed no serious lesion of the stomach.

<sup>1</sup> Concluded from page 613.

DR. F. P. KINNICUTT, of New York. In my paper, I distinctly stated that this lesion was found only in a certain number of these cases.

## A THIRD CONTRIBUTION TO THE STUDY OF LOCALIZED CEREBRAL LESIONS.

by DR. E. C. SEGUIN, of New York.

The first case reported related to the location of the facial centre. The patient, a boy of seven years, was first seen in January, 1885. He had been complaining of numbness in the right hand. The right leg and arm were slightly paretic. There was no headache and no aphasia. Shortly after, this clonic convulsive movement occurred in the right cheek, and both eyeballs were turned to the right. This lasted for over two hours. At times the speech was thick. There was no history of serious injury, and there was no evidence of pulmonary, renal, or arterial disease. There was no cranial tenderness on pressure. The tongue, when protruded, deviated to the right. The diagnosis was meningeal adhesion over the precentral region. Iodide of potassium was given in gradually-increasing doses, until from sixty to seventy-five grains were taken. Early in April of the following year, symptoms of tubercular meningitis developed, and the child died after an illness of three weeks. At the autopsy, the ordinary lesions of tubercular meningitis were found. In addition, there was a patch of adhesion situated over the left precentral gyrus and the caudal part of the second frontal gyrus. This was one inch in diameter. This would indicate that, in the human brain, the facial centre is in the caudal end of the second frontal convolution.

The second case related to the situation of the leg centre. A patient, aged forty-nine years, suffered with paresis of the right leg, and clonic spasm of the right abdominal muscles. There were right hemi-epileptic attacks, the spasm beginning in the abdominal muscles, and extending to the arm and leg. These attacks were repeated without loss of consciousness. Paralysis of the right leg, and paresis of the right arm developed. There was no aphasia, and no choked disc. Attacks of a syncopal character occurred, in one of which the patient died. At the autopsy, a large sarcomatous tumor was found, involving the cortex of the paracentral region gyrus. Two small nodules were found in the white substance below the principal tumor. This would indicate that the nerve-centre for the leg was in the paracentral lobule.

## DISCUSSION.

DR. JAMES J. PUTNAM, of Boston. With reference to the leg centre, I would report a case recently under my care: A man of forty-five, suffering with locomotor ataxia, probably of syphilitic origin, suddenly developed convulsions of the right arm and leg, without loss of consciousness, and without change in the voice. The symptoms relating to the arm entirely passed away, but the leg never recovered its normal condition. The patient died some time later, and, at the autopsy, a small hemorrhage was found at the lower edge of the paracentral lobule.

DR. F. T. MILES, of Baltimore. A patient of mine suffering with Bright's disease suddenly became hemiplegic, without the voice being affected. The arm and leg were affected. He rapidly improved, but the leg remained weak. He complained a great deal of a dragging in the shoulder. At the autopsy, the only

lesion that could be found was a hemorrhage of the size of a bean in the paracentral lobule.

Dr. H. M. LYMAN, of Chicago. Some months ago, I saw a case in which there was a sudden convulsion without loss of consciousness, the left arm being principally affected. These convulsions were repeated. There was a parietic condition of the left arm, which, in a few days, extended so as to involve the corresponding leg. The convulsive movements of the upper extremity continued to recur. They did not involve the face. The patient died, and a sarcoma was found on the right side, occupying the position of the centres for the arm and leg.

ON THE FREQUENCY WITH WHICH LEAD IS FOUND IN THE URINE, AND ON THE SYMPTOMATOLOGY OF CHRONIC LEAD-POISONING.<sup>2</sup>

by DR. JAMES J. PUTNAM, of Boston.

The following conclusions were presented:

(1) It is probable that lead may cause neurasthenic symptoms, which may exist for a long time without other signs of poisoning.

(2) The same is true of fine muscular tumor, especially if associated with debility.

(3) The most important conclusion is, that lead seems to cause, occasionally, a greater or less degree of the symptoms classed as spastic paraplegia, instead of the usual type of paralysis, with atrophy and loss of the deep reflexes.

(4) Additional evidence is furnished of the importance of suspecting lead as a cause of vague cerebral symptoms, such as are often due to syphilis.

(5) In one case of epilepsy in a person not predisposed, and where the probable first attack occurred at the age of twenty-five, besides the discovery of lead in the urine, there was a slight weakness and impairment of electrical reaction of the long extensors of the fingers.

Two cases of ataxia, with extensive muscular atrophy and other signs of peripheral neuritis, were reported, probably due to lead.

FORMS OF TYPHOID FEVER SIMULATING REMITTENT MALARIAL FEVER.

by I. E. ATKINSON, M.D., of Baltimore.

Continued fever simulating remittent fever is often observed in malarial localities especially, and is often regarded as such or as typho-malarial fever. While it is now generally recognized that the latter title does not designate a specific integral disease, every one admits the frequent concurrence of the two principles. The term is unfortunate, as misleading and encouraging lax habits of observation and treatment. The tendency to attribute the later evolution of frank typhoid symptoms from what at first appeared to be a malarial fever, to a transmutation of the latter disease to the former is of course unjustifiable. The theory that typho-malarial fever or continued malarial fever, is a combination of a septic and malarial poison as defended by Loomis and others, is rejected, for the reason that the term sepsis is used too indefinitely, and cannot explain facts in the course, history and pathology of the affection, which, however, may be perfectly reconciled with a typhoid origin. It is apparent that the term typho-malarial is made to include many groups of atypical cases. The object of the present paper is to describe forms of typhoid fever, in

which all the usually characteristic symptoms are absent, except mild fever. The cases commonly occur during the late summer and early autumn. They begin with a chill or insidiously, and assume a course of a mild remittent type, never passing into a typhoid condition, never developing the characteristic symptoms of typhoid, yet absolutely uninfluenced by anti-periodic treatment. They last three, four or even five weeks, and almost always end in slow lysis and recovery. They resemble malarial conditions, except in the persistence of fever, under strongly anti-malarial treatment, and in the occasional concurrence of circumstances pointing to a typhoid origin. There is no hebetude, the patient sleeps well, the tongue is slightly coated, there is almost never epistaxis; constipation is commonly observed, there are no bloody stools, no tympanites, no iliac tenderness, nor gurgling, and rose spots are usually absent. The patient is bright and cheerful. The more severe cases after beginning as remittents, may gradually evolve typhoid symptoms. Three cases were reported showing the type of fever described, occurring under conditions indicating their typhoid origin. While typhoid fever is one of the most characteristic of diseases, its special symptoms are very inconstant. There is not a sufficient realization of the mildness with which it often runs its course. Walking typhoid, although usually considered rare, is in reality frequent. Cases in which sudden accidents reveal their true nature, are probably but a small portion of the whole number. Our views of typhoid fever have been largely modified. Low ranges of temperature are now often encountered. Straube and Fraentzel and others, have reported severe forms of the disease with high mortality, although the temperature did not attain 102.2°. Normal and even sub-normal temperatures are sometimes maintained throughout the attack. In some cases a slight degree of fever heat is not at all uncommon. Liebermeister and others reports such cases. Loomis treats "mild typhoid" with walking cases, and states that the eruption appears early and is scanty and brief, and that diarrhoea is present in most cases. This is true of many cases, but there is a large class in which constipation is the rule and rose spots the exception; much larger than is generally admitted. Liebermeister and others described interesting examples. Dr. W. W. Johnson has most accurately described similar cases occurring in Washington. Malaria often complicates typhoid fever, but it oftener happens that its presence is assumed unjustifiably. A mental bias in favor of malaria is often strongly pronounced in the face of the strongest contrary evidence. The diagnosis of these cases from remittent malarial fever, often rests upon the crucial test of treatment. It is admitted that occasionally antiperiodic remedies fail to control the malarial paroxysm, especially in pernicious and adynamic forms. In milder forms the behavior under quinine, practically solves the difficulty. Where the full administration of the anti-periodic remedy, for a number of days, fails to terminate the attack, the diagnosis of typhoid fever becomes justifiable, and the prognosis can be made with a high degree of confidence. Not often earlier than the second, or later than the fourth week, the fever will terminate almost constantly by lysis, rarely by crisis. There are, however, exceptions, as shown by the occasional occurrence of death in walking typhoid and in other milder cases. Unquestionably, however, many cases of walk-

<sup>2</sup> To be published in full in a future number of the Journal.

ing typhoid are never detected. They may often, if examined, exhibit characteristic symptoms, diarrhoea, rose spots, splenic enlargement, etc., but in not a small number, these signs are not discovered. The true nature of many of these milder cases is never recognized, and the pathological responsibility is thrown upon febricula, simple continued fever, gastric fever, bilious remittent fever, remittent malarial fever, etc. In the future, a solution of the difficulty will be obtained through the knowledge derived from bacteriological research and culture observations.

## DISCUSSION.

DR. WILLIAM H. DRAPEL, of New York. I see many cases in New York which have been diagnosed as typho-malarial fever which I consider to be cases of typhoid fever. I think that the diagnosis of typhoid fever can be usually made in the course of the first week of the disease, by attention to the characteristic course of the fever. The nervous symptoms of typhoid fever are of great importance in the diagnosis. In considering a disease like this, we should study it in its totality, and not in its elementary parts.

Dr. Atkinson has spoken of the aid given by quinine, in the diagnosis. My own experience confirms that of others, with reference to the use of quinine as an antipyretic in typhoid fever. Unless used in such doses as to produce a certain degree of collapse, it is useless. I believe that it does nothing more than to increase the discomfort of the patient. If in five or six days the use of quinine does not succeed in checking the fever, we may conclude that we are dealing with a continued fever of the nature of typhoid.

DR. JOHN GUTERAS, of Charleston. I have had an opportunity of studying these cases, both in the North and in the South, and I have come to a conclusion different from that expressed by the author. These cases present no symptom of typhoid fever with the exception of the continued fever, and this is a strong argument against their being typhoid. These cases are so numerous as we go farther South, that I would class them as a separate disease. I have examined some of these cases of prolonged continued fever of Southern countries, post-mortem, and have failed to find the lesions of typhoid fever. In the South we have these three diseases, malarial remittent fever at one end, typhoid fever at the other, and between these we have cases of the kind described by Dr. Atkinson. My view of this fever is, that it belongs to the class of functional fevers. A simple continued fever may be set up by an excessive demand made upon any of the important functions of the body. I have thought that in warm climates where constant exertion was required on the part of the heat centres to keep within limits the production of heat, a paralytic condition of these centres might be induced, especially towards the close of a long and hot summer. This fever presents none of the symptoms of a malarial affection, and is quite common in sections where malaria is unknown.

DR. A. JACOBI, of New York. I think it a mistake to say that those cases in which the fever cannot be broken in five or six days by quinine are not malarial. There are cases of remittent fever that will not be broken by quinine. There is one assistance in diagnosis which I have not heard alluded to, and that is the urine-test. This has frequently been of much service to me. It is prepared as follows:

Solution No. 1: Sodium nitrite, one part; water, two hundred parts.

Solution No. 2: Sulfanilin acid, five parts; concentrated muriatic acid, five parts; water, one hundred parts.

Add one-and-one-fifth parts of the first solution to fifty parts of the second.

Equal parts of this mixture and the urine are to be mixed. Then add about sixty or seventy per cent. of aqua ammonia. In normal urine there will only be a slight discoloration, while in urine from typhoid fever there will be a deep purple discoloration. This test is rarely applicable during the first two or three days. It generally can be applied up to the fifteenth or eighteenth day. It should also be stated that, in cases of acute miliary tuberculosis, the same reaction is obtained.

DR. W. W. JOHNSTON, of Washington. It is well known that in places where malaria has largely prevailed, as cities have grown and drainage improved, malarial affections have diminished, and typhoid fever has increased. This has been the case in Washington. It has also been observed in London. The cases of typhoid fever which I have observed may be arranged into three groups: Those in which all the symptoms have been present; those in which only one has been present; and those in which all the symptoms, with the exception of the fever, has been absent. I see no reason, clinically, for saying that these cases which present the typical temperature of typhoid fever are not cases of this disease. It is not necessary that the temperature should reach any special degree. Any temperature, provided it presents the typical curve, may be characteristic of typhoid fever.

DR. R. H. FITZ, of Boston. An epidemic of an anomalous form of fever recently occurred in Boston, among a number of emigrants. The diagnosis lay between typhoid and typhus fever. It was concluded that they were cases of typhoid fever. One case ended fatally. The intestinal lesions were of the most trivial character. The enlargement of Peyer's patches was no greater than is seen in many cases of enteritis. The lesions were so superficial, that it seemed quite probable that they would have disappeared if the patient had lived a few days longer.

DR. ISRAEL T. DANA, of Portland. Some of the cases to which Dr. Fitz has referred found their way to Portland, and one of them died there. The autopsy in this case showed well-defined, but not complete, lesions of typhoid fever. I believe that this is what will generally be found: that the atypical cases will present lesions as imperfectly developed as the symptoms.

DR. W. J. COUNCILMAN, of Baltimore. I had expected to hear some allusion made to the examination of the blood as a means of diagnosis. I think that a simple examination of the blood will enable us to differentiate between the continued malarial fevers and typhoid fever. The organisms found in these cases of continued malarial fevers are very easy to recognize. They are large, crescentic forms, free in the blood, and not contained in the corpuscles. They do not require a high power for their detection.

DR. WILLIAM OSLER, of Philadelphia. I quite agree with the last speaker that we have, in the microscopical examination of the blood, a positive means of diagnosis. I have no doubt that in these doubtful cases, a careful examination of the blood will determine whether they are malarial or not, while a careful

examination by culture methods will determine whether or not it is a case of typhoid fever.

I have had three instances in which the examination of the blood aided in the diagnosis. One was a case of continued malarial fever, thought to be typhoid. Another was a case of remittent fever, supposed to be typhoid. In both these instances, examination of the blood showed the case to be malarial. In the third instance the patient had a chill, which was repeated. It was supposed to be a case of remittent fever, but the malarial organisms were not found. The case pursued an atypical course, and when two weeks advanced in convalescence, had a well-marked relapse of typhoid fever.

DR. I. E. ATKINSON, of Baltimore. I have been much interested in the remarks made by Dr. Guiteras. The cases which I have reported were, I think, cases of typhoid fever. I have never seen death in these atypical cases. I claim that the cases of fever which occur in this locality, and which present the characters which I have described, are cases of typhoid fever, and not of malarial fever.

#### EXECUTIVE SESSION.

The report of the Committee on the Congress of American Physicians and Surgeons was received and adopted, and Dr. William Pepper, of Philadelphia (with Dr. Reginald H. Fitz, of Boston, as alternate), was appointed as the representative of this Association.

#### OFFICERS FOR THE ENSUING YEAR.

*President*, Dr. William H. Draper, of New York. *Vice-Presidents*, Dr. Francis Minot, of Boston, and Dr. J. Palmer Howard, of Montreal. *Recorder*, Dr. William Osler, of Philadelphia. *Secretary*, Dr. Henry Hun, of Albany. *Treasurer*, Dr. W. W. Johnston, of Washington.

The following were elected to active membership: Drs. A. V. Meigs, Louis Starr, and J. H. Musser, from Philadelphia; Dr. James E. Reeves, from Wheeling, W. Va.; Dr. William H. Whitney, from Boston; Dr. James Stewart, from Montreal; and Dr. M. Allen Starr, from New York.

Dr. John S. Billings, of Washington, was elected to honorary membership.

Adjourned.

#### THE AMERICAN LARYNGOLOGICAL ASSOCIATION.<sup>1</sup>

##### NINTH ANNUAL CONGRESS.

##### A CASE OF STENOSIS OF THE LARYNX TREATED BY DIVULSION AND SYSTEMATIC DILATATION,

by MORRIS J. ASCH, M.D., of New York.

Miss K., up to the age of twenty-seven years enjoyed good health. She then had some pulmonary trouble, the exact nature of which could not be ascertained. In 1884, she had some wheezing in breathing, with slight cough. These symptoms increased in intensity gradually, and in May, 1885, the patient came under the observation of the author. There was at this time great dyspnea, which was increased by lying down. Examination of the throat showed no abnormality in the larynx or above the cords. Below the cords there were two white swellings united by a membrane posteriorly. The opening of the larynx was diminished to one-third of the normal size. The

membrane was cut, and divulsion performed. This caused great improvement. Later, metallic sounds were used daily and the forceps once a week. She grew much better and ceased attending. In September, she again returned, with the difficulty of the breathing as great as before. This was the result of acute inflammation of the larynx. Under the use of steam and cold compresses the swelling subsided. O'Dwyer's tubes were tried, but they at once produced spasm, and were coughed out. Schroeder's hard rubber tubes were then used, and within three months the cure was perfect. All the symptoms have now disappeared. There was no history of syphilis, and no history of previous inflammation. The trouble was evidently the result of subchordal hypertrophic laryngitis.

DR. J. SOLIS COHEN, of Philadelphia. My experience in stenosis of the larynx has been limited. In one case, reported twenty years ago, I removed a morbid growth by thyrotomy after it had been destroyed by the internal use of the galvano-cautery, which was probably the first use of the galvano-cautery for this purpose in the United States. The growth had been examined by several microscopists who pronounced it epithelioma, but this was evidently an error, as the patient still lives. On this supposition, I separated the thyroid cartilage and removed the tumor with one vocal cord. Preliminary tracheotomy had been performed ten days previously. The operation was followed by adhesion of the vocal cord to the tissue of the opposite side. I then devised an instrument to cut this adhesion. I have never had the courage to attempt dilatation of the larynx without previous tracheotomy. I think it better to perform tracheotomy, so as to have nothing to interfere with the breathing and then pursue the most active measures for the relief of the stenosis. When the operation is performed with antiseptic precautions, the tracheotomy wounds heal up in a very short time. I have seen it closed within four or five days of the operation. I think that the danger from the operation is less than the risk of injury from the other methods of treatment.

DR. E. C. MORGAN, of Washington. I recently had under treatment a case of laryngeal stenosis. During a period of eight or ten months I was enabled to control this by the administration of iodide of potassium and by local applications of iodo-glycerine to the larynx. Finally, the disease advanced so far that on several occasions I advised tracheotomy to be followed by dilatation. The patient postponed the operation a number of times, although warned of his danger. He had at times suffocative spells at night, and finally, succumbed to one of these spasmodic attacks. I think that if tracheotomy had been allowed and dilatation performed, that man would have been alive to-day.

DR. D. BRYSON DELAVAN, of New York. The various forms of dilators used in these cases are likely to be replaced by O'Dwyer's tubes. This method has a most promising future before it. The tube can be left in for a length of time and respiration not interfered with.

##### ON THE ETIOLOGY OF DEFLECTIONS OF THE NASAL SEPTUM.

by DR. D. BRYSON DELAVAN, of New York.

##### FOREIGN BODY IN THE LARYNX.

by DR. S. W. LANGMAID, of Boston.

<sup>1</sup> Concluded from page 615.

The patient came under observation three months after swallowing a pin about two inches in length. The pin had lodged in the throat, and immediately after the accident an unsuccessful effort had been made to remove it with the bristle probang. At the time that she came under the speaker's notice, there were ulcerations of the larynx which were relieved by treatment. Two years later the patient again presented herself and an examination showed the pin, which had emerged from the ventricular band with the head down. It was with some difficulty removed.

DR. J. SOLIS COHEN, of Philadelphia, stated that in several instances he had seen on examining the pharynx what appeared to be the belly of a muscle above the mouth of the Eustachian tube, and that from this there extended to the fornix of the pharynx what looked like a tendon. This he had seen on both sides. He asked whether or not any of the other members had observed the same appearance.

#### RECURRENT NASO-PHARYNGEAL TUMOR. CURE BY ELECTROLYSIS.

by DR. RUFUS P. LINCOLN, of New York.

The patient presented himself in April, 1886. A growth had been removed from the posterior nares by another physician one year previously. It returned, and the operation was repeated six months later. When the patient came under observation he was unable to breathe through the left nostril. On examination a large growth was found occupying the left half of the posterior nares, and it was decided to treat this by electrolysis. On June 3d, two needles connected with the negative pole of the battery were introduced through the anterior nares into the growth, while the positive pole terminated in two large sponge electrodes which were applied to the front and back of the chest. In all, sixteen applications were made at intervals of three or four days. This caused an entire disappearance of the growth. The immediate effect of the electrolysis was to cause distension and a change in the color of the growth, but these passed off in the course of twenty-four hours. There is up to the present time no evidence of the return of the growth.

DR. F. H. HOOVER, of Boston. In October, 1881, a youth presented himself with a tumor extending from the tip of the right nostril into the naso-pharyngeal cavity. There had been a great deal of hemorrhage and the patient was in a bad condition. He was sent into the hospital and operated on by Dr. J. C. Warren, with the galvano-cautery snare, and the whole mass removed in one piece. From that time to this the patient has been constantly under treatment. The tumor has been growing, and from time to time I have snared it off. The tumor has been pronounced to be a most malignant form of myxo-sarcoma, but the general health is excellent. I propose next to try the effect of electrolysis.

DR. D. BRYSON DELAVAN, of New York. During the past fifteen years I have seen a number of these patients operated upon, and I recall many cases in which the result was disastrous. Although there have been successful cases, none have come under my observation. The great point is in the early diagnosis. If taken in time, even if it cannot be cured, it can, as a rule, be kept in check. After the age of twenty-five years, it has been stated that these tumors have a tendency to stop growing, so that if kept in check until this age, they may entirely disappear. It

seems to me that the galvano-cautery exercises a modifying influence on the tissues which remain, which cannot be caused by the knife.

#### TWO UNIQUE CASES OF CONGENITAL OCCLUSION OF THE ANTERIOR NARES.

by W. C. JARVIS, M.D., of New York.

Complete congenital occlusion of the anterior nares is rare, and the author had been unable to discover any cases in searching the literature of the subject. The first case was a young man eighteen years of age, with complete closure of both nostrils. Inspection showed on each side within the anterior nares, a cup-shaped depression of white glistening membrane. On the left side a small hole was discovered. The operation was performed in April, 1886. The burrs devised by the speaker, connected with an engine, were used to cut through the cartilaginous occlusion. This was accomplished in a few minutes; the air passed freely through the nostril. At a subsequent operation the right nostril was opened. In April, 1887, the opening in the right nostril had become contracted and had to be reopened. A second case in which the anterior nostrils were included by an osseous occlusion, the operation was performed in the same manner as in the previous case, with successful result.

#### AFTERNOON SESSION.

#### A COMPARATIVE STUDY OF SOME OF THE METHODS OF TREATMENT BEST ADAPTED TO THE RELIEF OF OCCLUSION OF THE POSTERIOR NARES.

by DR. ALEXANDER W. MACCOTY, of Philadelphia.

He confined his remarks to occlusion due to enlargement of the soft parts. He had never seen occlusion of the posterior nares due to osseous growth. He referred to the methods used in the treatment of occlusion of the posterior nares, and highly recommended the use of chromic acid fused on the end of a probe, the end of which is covered with a tube which is withdrawn when the probe has reached the desired position. This is followed by the use of an antagonistic solution. He had found this better than the use of the galvano-cautery. Since using cocaine, he had not been able to use the cold wire snare in these cases, on account of the contraction caused by the drug. He had also found difficulty in using the needles recommended by Dr. Jarvis. The chief object of the paper was to call attention to the superiority of chromic acid used in this way, over the other methods of treatment which had been recommended. He did not recommend the use of the acid either in crystal or in solution, for then it was not easy to limit the application to the desired point.

DR. W. C. JARVIS, of New York. I never use cocaine as a preliminary measure where I intend to remove posterior hypertrophies. I first include the hypertrophies in the loop, and draw the wire home and then apply the cocaine-spray. The tissue included in the loop cannot be affected by the contraction produced by the drug. We thus have the advantages of the anesthetic without its disadvantages. It has been pretty generally recognized that chromic acid has many disadvantages. It may produce serious symptoms. The snare will accomplish in a few minutes what chromic acid requires considerable time to do.

DR. C. C. RICE, of New York. I agree in the main with what the author of the paper has said. The turbinated bodies are difficult to penetrate with the

needles, and there are many cases in which it is difficult to apply the loop posteriorly. I have not found any special disadvantages in the use of chromic acid.

DR. D. BRYSON DELAVAN, of New York. I formerly used chromic acid, but then gave it up. Lately I have again tested it, selecting for this purpose five patients, three of whom were physicians. I added enough water to the crystals to make them deliquesce and then applied it with a cotton-wrapped probe, the excess of acid having been removed. I have also used it by fusing it on a probe. In all these cases there was more reaction than follows the use of the cautery or the snare, and all the patients preferred the cautery to the chromic acid.

#### PLASTER-OF-PARIS DRESSING FOR FRACTURE OF THE NOSE,

by DR. J. W. ROBERTSON, of Detroit, read by title,

DR. DEBLOIS, of Boston, exhibited a plaster splint which he had employed with advantage in a case of fracture of the nose. The splint consisted simply of a plaster cast into which a piece of roller bandage had been incorporated. This was applied over the nose, and held in position by the strips of bandage.

DR. J. O. ROZ, of Rochester, exhibited a nasal saw run by an electric motor.

#### EXECUTIVE SESSION.

The report of the Committee on the Congress of American Physicians and Surgeons, was presented, received and adopted.

The following are the officers for the ensuing year: President, DR. R. P. LINCOLN, of New York; Vice-Presidents, DR. J. N. MACKENZIE, of Baltimore, and S. W. LANGMAID, of Boston; Secretary and Treasurer, DR. D. BRYSON DELAVAN, of New York; Librarian, DR. T. R. FRENCH, of Brooklyn; Council, DR. FRANK DONALDSON, of Baltimore, J. SOLIS COHEN, of Philadelphia, F. H. HOOPER, of Boston, and E. C. MORGAN, of Washington.

The following were elected Corresponding Fellows: DR. A. GUGENHEIM, of Paris, and J. MOURE, of Bordeaux. DR. A. JACOBI, of New York, was elected Honorary Fellow.

The Association then adjourned.

#### AMERICAN MEDICAL ASSOCIATION.<sup>1</sup>

THIRTY-EIGHTH ANNUAL SESSION, CHICAGO, JUNE 7TH, 8TH, 9TH AND 10TH, 1887.

#### FOURTH DAY.

There was a large falling off in the attendance at the session of the American Medical Association at Central Music Hall. The Rev. Dr. Vibbert offered prayer, after which the Nominating Committee presented a final report, recommending that the following be appointed to deliver addresses before the Association next year: On Medicine, R. BEVERLY COLE, of California; on Surgery, F. M. MOORE, of Rochester, N. Y.; on State Medicine, J. P. CONNELL, of Virginia. They also reported a resolution that a committee of three be appointed to notify the gentlemen, and to fill any vacancies that might occur. The report was adopted, and Drs. Toner, of Washington; Gussone, of

North Carolina; and Colvin, of New York, were appointed.

Surgeon-General Hamilton offered a resolution by which the Government was to print the reports of Dr. Sternberg, for the benefit of the medical profession. The resolution was adopted.

DR. J. S. MARSHALL, Chairman of the Section of Dental and Oral Surgery, read his annual address, in which he pointed out the rapid strides made in dentistry of late, and that the effort now was to save teeth, rather than extract them, the latter course only being pursued as a last resort. He entered a protest against the principles set forth in medical articles relative to the filling of teeth causing disease of the facial muscles, and advocated that, in every medical college, a professorship of dental surgery, by which the students would receive, at least, a theoretical knowledge of dental and oral surgery, and the treatment of diseases of those classes, and be enabled to advise their patients how to take care of their teeth, and when to consult a dentist. The address was ordered printed.

DR. I. N. QUIMBY, of New Jersey, Chairman of the Section on Medical Jurisprudence, read an address, in which he traced the origin of a medical jurisprudence, reviewed the creation of the office of coroner, the application of law to medicine, laws regulating marriage, etc., and then passed on to criticize feticide and infanticide, asserting, amid applause, that the destruction of the fetus at any period of gestation was murder, and God forbid that any physician should be tempted by appeals, or a fee, however large, to become the assassin of the human race at any period of gestation. He suggested that a committee be appointed to report at the next meeting on the criminality of feticide, and that measures be at once commenced for legislative action for its punishment. He also asserted that the countries of Europe are foisting a large number of their insane on this country, which apparently increases the ratio of insanity in this country, when, in fact, the ratio is not increasing. He then drew attention to the increased use of alcoholic stimulants, and, after much study, and a good deal of close attention to the subject, he had arrived at the conclusion, which would be regarded as a radical one by many, that drunkenness was a wilful act, for which the drunkards should be held responsible before the law, and that it would never be repressed by fining the dealers or retailers of spirits. He also held that the State, by licensing saloons, became *particeps criminis*, and denied that drunkenness was a disease. He closed with a hope that the medical profession had something to do with drunkenness, and should do all in its power to destroy the hydra-headed monster, which is stalking through so many homes, and committing every conceivable description of crime. The address was referred to the Committee on Publication.

DR. TONER, from the Committee on Necrology, reported that the Massachusetts delegation had informed him of the death of forty members during the past ten years, and he wished the members would report promptly the demise of any members.

The next business was the report of the standing committee on meteorological conditions and the relations to the prevalence of disease; also concerning the collective investigation of disease, in cooperation with the committee of the British Medical Association. DR. DAVIS, chairman of the committee, said he had collected a lot of information, but had not had time to

<sup>1</sup> Continued from page 637.

arrange it for a report, and it was not in such a shape that he could let any one else do so. He therefore reported progress. The report was accepted, and committee continued.

Dr. DAVIS then offered a resolution providing that graduates of dental colleges which required a standard of general education and a term of study equal to the best medical colleges, and a curriculum embracing the entire fundamental branches of medicine, but substituted practical and clinical instructions in oral and dental surgery, and medicine for clinical instruction in general medicine and surgery, be admitted members of the Association. Such a resolution, if passed, would remove a source of embarrassment, and tend to induce dental colleges to raise their standard.

The resolution was seconded and carried *nem. con.*

Dr. Davis then offered a resolution that, in future, the Committee of Arrangements reserve the third evening of the session for a dinner of the Association, the members to be at liberty to attend or not, as they pleased, and to put their names down for tickets with or without wine, as they chose. They would then be enabled to meet around one board and spend an evening in harmony, without any one being compelled to pay for wine for some one else to drink, and guard against the extravagance which heretofore existed, when the banquet cost \$10,000.

The motion was seconded and adopted.

Dr. WILSON moved that an honorarium of \$300 be granted to the Secretary.

Dr. BALDWIN seconded the motion.

Dr. DAVIS said, after giving \$1,000 to the International Medical Congress Committee, that would about use up their balance, as it was the wish of the Association that the report should be made more valuable, and the trustees had been ordered to use all available funds for that purpose, he moved, as a substitute, that the trustees be constituted a finance committee, to which should be referred all matters of finance, consideration and report.

The substitute was adopted, and, on being put as a substantive motion, was adopted.

The SECRETARY read a telegram from Dr. Alexander Y. P. Garnett, the new President, acknowledging the honor conferred upon him by his election and regretting that the exigencies of his profession prevented his making his acknowledgment in person. The despatch was ordered entered on the minutes.

The Committee on the Sanitary Condition of Emigration Vessels, of which Dr. Bell is Chairman, was requested to continue its labors.

On motion of Dr. WOOD, a committee of three was appointed to report at the next meeting on the subject of "Dietetics." Drs. Wood, J. T. Whitaker, and F. Woodberry, being the Committee.

Dr. BRODIE moved a vote of thanks to the Committee of Arrangements and the residents of Chicago for the entertainment they had received, and also to the press for reporting the proceedings, which was adopted.

The PRESIDENT then said: Gentlemen, my work is finished. I wish it were done better; it has been done the best I could. There is nothing for me remaining but to say: "Thanks, good-bye, God bless you." I would gladly introduce to you your new President, but that is out of the question. I have learned that he is a man; that he possesses those qualifications which will be in keeping with the men who

have gone before him in this office; that he is a man of character, possessing all those qualities of mind and heart and capability which will insure success in his new position. I remember, thirteen months ago, the only man I envied was Dr. Brodie, the retiring President. I am proud to have been your President, and it will always be a pleasant remembrance. It only remains for me to add that you have honored and trusted me, and been most deferential and indulgent, and I offer you my heart's sincerest thanks. I now declare the meeting adjourned *sine die*.

## Recent Literature.

*The Science and Art of Obstetrics.* By THEOPHILUS PARVIN, M.D., LL.D. 8vo, pp. 701. Philadelphia: Lea Brothers & Co. 1886.

This is a scholarly work, and an ornament to modern obstetric literature. The style is clear and polished; the illustrations are numerous and accurate; the typography and press-work are of the uniformly high standard of excellence that is always expected of the publishers.

The book is especially distinguished for its wealth of historical allusions and for its profuse quotations of authorities. These features make the work one of peculiar value to the physician, but render it less desirable for the student. Undergraduates require, we believe, more dogmatic teaching, and had better leave the conflicting opinions of various authorities for the consideration of their maturer years. The student-physician, however, will delight in, and profit by, Professor Parvin's work, and to him we especially recommend it.

*Texas State Medical Association. Report of the Special Committee on Surgery.* Presented at the Annual Meeting, at Dallas, April 27, 1886. GEORGE CUPPLES, M.D., Chairman and Reporter, Austin, Texas. 1886.

As the title suggests, the book is a statistical record of the surgical work done in Texas previous to 1886. It represents the work of one hundred and thirty-eight surgeons, and has been compiled by the editors, a committee of the Texas State Medical Association, from the answers returned to their circulars. The cases are classified and arranged in tables quite convenient for rapid reference. Sixty-five pages are devoted to a detailed synopsis of 4293 operative cases, giving in each the age, sex, race, character of operations performed, name of surgeon, and result. Also, if antiseptic treatment was employed or not, the kind of anesthetic, and a summary of remarks. The remaining eleven pages of the work are occupied by abridged tables containing a synopsis of the general results obtained in each class of cases.

The results shown by this report are quite interesting; and the system adopted in the arrangement of the entire work very satisfactory. Carbolic acid has been the antiseptic most extensively used; and chloroform the most popular anesthetic (In 3179 of 3547 cases, with one death). Such reports, if issued annually, and with proper attention to accuracy in collecting and compiling the material used, will furnish the profession in a few years with much interesting valuable data.

THE BOSTON  
Medical and Surgical Journal.

THURSDAY, JUNE 30, 1887.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,  
94 BOYLSTON STREET, BOSTON, MASS.

SCARLATINA CONVEYED BY MILK.

THAT scarlatina is occasionally transmitted through the medium of cow's milk is a fact which, of recent years, has been gradually assuming certainty in the minds of sanitary authorities. In view of the fact that other substances, when infected through diseased persons, were capable of carrying the infection, it was naturally supposed that milk acted in a similar way with other fomites, receiving its infection from some human being.

In 1881, Mr. Ernest Hart presented to the International Medical Congress the tabulated facts concerning all the milk epidemics which had been reported up to that time. Many of these had been investigated by the Local Government Board. In most of Mr. Hart's cases, the facts seemed to show that the origin of the infection, carried through the milk, had been in the human body, and in none was that possible origin disproved.

A class of cases began, however, to accumulate, in which the possibility of a directly human origin of the infection was not excluded, yet a careful study of the date of the outbreaks made it difficult to reconcile this view of a human origin to the disease with what is known of the period of incubation of scarlet fever. For instance, an epidemic of scarlet fever and sore throat occurred at Oxford, Eng., in 1882, among the persons supplied with milk from a dairy of three cows. The earliest cases of the outbreak occurred March 10th, and most of them developed several days later. The dairyman's child had had scarlet fever, and a young woman had had diphtheria, but the latter had been removed March 1st, and the former March 3d, and with the latter date, all chance of direct infection from these or any other persons ceased. The period of incubation of scarlet fever is, as a rule, less than seven days, yet almost all the cases developed from eight to twelve days after the patients were taken away, and the cows put into new hands. The suspicion arising in this case that the cows themselves may

have been at fault, was not confirmed by any actual evidence of such disease.

We have already laid before our readers<sup>1</sup> the particulars of two epidemics of scarlatina, investigated by the British Local Government Board, one in 1882, at St. Giles and St. Pancras, and the other in 1885, at Marylebone, from a dairy at Hendon, both cases showing a very strong presumption that scarlatina had been conveyed to human beings through the channel of milk, from a disease in cows, itself analogous, if not identical, with scarlet fever. As we remarked at that time, there was still lacking the evidence of inoculation into the human subject of a milk sub-culture, or of feeding of calves with such milk-cultures as appear to have been fed to children. The first of these proofs can hardly be expected, but the second has now been offered with considerable detail and conclusiveness by Dr. E. Klein, F.R.S., who has worked upon the matter at the instance of the Board, and who has given the result of his inquiry in a recent address before the Royal Institution. He finds that a microbe, the *micrococcus scarlatinae*, is the cause of human scarlet fever. Further, that it produces in bovine animals a disease identical with the Hendon disease and human scarlet fever, and that, consequently, while the cow is susceptible to infection with human scarlet fever, it can, in its turn, be the source of contagium for the human species, as was, no doubt, the case in the milk epidemic from the Hendon farm.

These conclusions are reached by Dr. Klein from observations and experiments showing that, in the blood and tissues of persons affected with scarlet fever, there occurs the same micrococcus that was present in the cow, both being identical in microscopical and in cultural characters. In the second place, it was found that the action of this microbe on animals is exactly the same as the micrococcus found in the Hendon cows. Calves and mice, after inoculation or feeding with a trace of the growth of both sets of micrococci, become affected with cutaneous and visceral disease, similar to human scarlet fever. In calves, the disease was of the same mild type as in the Hendon cows. Further, it was shown that from the blood and the tissues of these animals infected with one or the other set of cultivations, the same micrococcus was recovered.

Dr. Klein, furthermore, adds that he has found the micrococcus of scarlatina in several cans of a cheap brand of condensed milk, which was supposed to have given rise to scarlatina in persons who partook of it. The microbe is identical, he claims, with that obtained from the Hendon cows and from human scarlet fever, and inoculation experiments with it in calves and mice produced the same disease that arose from inoculation with the microbe, as obtained from the cow and from the human patient. This brand of condensed milk, it should be said, was not raised in the manufacture to a temperature high enough to destroy the micrococcus.

Again, there occurred during the beginning of this year, a severe epidemic of scarlet fever in Wimbledon.

<sup>1</sup> Vol. CXIV, p. 601. Vol. CXV, p. 115.

This epidemic was also traced to milk coming from a particular farm. In one of the houses supplied with this milk, there occurred cases of scarlet fever among human beings, and at the same time, a pet monkey, which also consumed a good deal of the milk, became ill; it died after five days. Dr. Klein made a post-mortem examination of this animal, and had no doubt about its having died of scarlet fever. From the blood of the monkey, he obtained, by cultivation, the same micrococcus as was obtained from human scarlet fever, from the Hendon cows, and from the condensed milk. Experiments made on animals with this micrococcus of the Wimbledon monkey showed that the same disease was produced both by inoculation and by feeding.

It will readily be seen that the corner-stone of Dr. Klein's demonstration of the production of scarlet fever in the human subject from disease in the cow, consists in the validity of his *micrococcus scarlatinae* as the cause of true scarlet fever in the human subject. On this point, we must await the final verdict of the micro-biologists. It is to be said that most of the previous discoverers who have described the microörganism of scarlatina have found it to be a micrococcus, among them Klebs, Coze and Feltz, Babes and Cornil. Eklund, of Stockholm, described in detail the microbe as a micrococcus, multiplying by fission, and named it *Plax Scindens*. Yet, on the other hand, the germ has been said by other authorities to be a bacillus, and even coincidentally with the announcement by Klein, two observers of the University of Edinburgh, Drs. Jamieson and Edington, have completed a series of observations, showing, to their satisfaction, a bacillus in the tissues of scarlatinous patients capable of cultivation, and inoculable in calves and other animals, with the result of producing true scarlatina in them.

The British Dairy Farmers' Association naturally felt somewhat disturbed by the report of Drs. Powers and Klein on the Hendon epidemic, and employed Professor Axe to investigate the subject. His report was published by the Agricultural Department of the Privy Council Office. He confesses to not having seen the affected cows until the characteristic eruption had, in almost all cases, disappeared. Nevertheless, he appears, as we judge from comments on his report, the document itself not being at hand, to have assumed that the disease was identical with another disease having a vesicular eruption, which latter did not convey scarlatina. His conclusions are evidently of small value in comparison with the observations of the officers of the Local Government Board, and their chief value would appear to be in illustrating the need of more careful study by veterinarians of the various eruptive diseases of the cow.

Dr. Klein believes that the milk of scarlatinous cows may convey the infection in two ways: both as a secretion of a diseased animal, and from the mingling in it of contagious particles brought off from the udder by the hands of the milker. He finds that a temperature of 85° C. (185° F.) will destroy the micrococcus of

scarlatina, and hence recommends that the milk be heated to that point, though not necessarily that it be boiled, before it is consumed.

#### A NEW BILL TO REGULATE THE PRACTICE OF MEDICINE IN ILLINOIS.

A BILL amendatory to the existing act passed the Senate of Illinois, May 10th, and the House of Representatives June 15th. It has received the Governor's signature and goes into effect July 1st. By it three classes of persons are specified as alone allowed to practice medicine in that State; (1) graduates in medicine from legally chartered institutions in good standing, who have presented their diplomas to the State Board of Health, for verification as to genuineness. (2) Those who, not possessing diplomas, have passed an examination satisfactory to the Board. (3) Those who have practised in the State for ten years; but these persons must, if they have not already done so, obtain a certificate to that fact from the Board of Health within six months of the taking effect of the act in order to secure registration. The certificates granted are to be signed by all the members of the Board and for each certificate of authority to practice general medicine the recipient is to pay five dollars into the treasury. For the certificate in midwifery the fee is two dollars.

All examinations of persons not graduates or licensees are to be made directly by the board, and the certificates given by the board authorize the possessor to practice medicine and surgery in the State of Illinois.

The fees for the examination of non-graduates are fixed as follows: Twenty dollars for an examination in medicine and surgery, ten dollars for an examination in midwifery only, to be paid into the treasury of the board. If an applicant fails to pass the examination, his or her fee is to be returned. Upon successfully passing the examination the certificate of the board issues to the applicant without further charge.

The State Board of Health may refuse to issue certificates to individuals guilty of unprofessional or dishonorable conduct, and it may revoke such certificates for like causes. In all cases of refusal or revocation the applicant may appeal to the Governor, who may affirm or overrule the decision of the board, and this decision shall be final.

Among the other important provisions of the act are the following:

"SECT. 10. Any person shall be regarded as practising medicine, within the meaning of this act, who shall treat, operate on, or prescribe for any physical ailment of another. But nothing in this act shall be construed to prohibit service in cases of emergency or the domestic administration of family remedies. And this act shall not apply to commissioned surgeons of the United States Army, Navy or Marine Hospital Service in the discharge of their official duties.

"SECT. 11. Any itinerant vendor of any drug, nostrum, ointment or appliance of any kind, intended for the treatment of disease or injury, or who shall, by writing or printing or any other method, profess to cure or treat disease or deformity, by

any drug, nostrum, manipulation or other expedient, shall pay a license of one hundred dollars per month into the treasury of the board, to be collected by the State Board of Health, in the name of the People of the State of Illinois for the use of said Board of Health. And it shall be lawful for the State Board of Health to issue such license on application made to the State Board of Health, such license to be signed by the President of the Board, and attested by the secretary of the board, with the seal of the board. Any such itinerant vendor who shall vend or sell any such drug, nostrum, ointment or appliance without having a license so to do, shall, if found guilty, be fined in any sum not less than one hundred dollars, and not exceeding two hundred dollars for each offense, to be recovered in an action of debt before any court of competent jurisdiction. But such board may for sufficient cause refuse such license."

The penalty for practising medicine or surgery without the certificates issued by this board is one hundred dollars for the first offense, and two hundred dollars for each subsequent offense, the same to be recovered in an action of debt, before any court of competent jurisdiction: any person filing or attempting to file as his own the diploma or certificate of another, or a forged affidavit of identification is declared guilty of a felony, and upon conviction, will be subject to such fine and imprisonment as are made and provided by the statutes of the State for the crime of forgery.

Upon conviction of either of the offenses mentioned in this act, the defendant is to be committed to the common jail of the county until the fine and costs are paid. But either party may appeal in the same time and manner as appeals may be taken in other cases, except that where an appeal is prayed in behalf of the people, no appeal bond is required to be filed, whether the appeal be from a justice of the peace, or from the county or circuit court or from the appellate court. That is, the State Board of Health may appeal its cases without bond.

#### MEDICAL NOTES.

—The United States Consul at Baranquilla, under date of May 26, forwards a copy from the *Star and Herald*, of Panama, under date of May 19, relative to the inoculation for the prevention of yellow fever, as follows: "A letter from Cucuta, Santander, dated April 14th, says: 'On the 6th, I sent you a telegraphic message containing important information. I told you how successful inoculation is proving here for yellow fever. About ten per cent. of the inoculation patients are attacked by the disease, but none of them die. The heat is intense; ranges between 34° and 38° centigrade.' Cucuta is not far from the place where yellow fever seems to have its headquarters." At Key West thirty-one cases of yellow fever and eleven deaths were reported up to June 18th.

BOSTON.

—During the recent Annual Meeting of the Massachusetts Medical Society the following interesting operations, the description of which reached us too late to be inserted in our report of the meeting, were performed in the amphitheatre of the Massachusetts General Hospital before a large number of the Fellows. Dr. Beach performed an excision of the knee for anchy-

losis with deformity, following tubercular disease of the joint; removed a congenital cyst from the upper eyelid and border of the orbit; applied the actual cautery for recurrent epithelial disease of the face; tapped a hydrocele, withdrawing three quarts of serum; and removed two uric-acid calculi, weighing thirty-one and twenty-nine grains respectively, by lateral lithotomy, from a three-year-old child. Dr. John Homans removed a tumor of the neck, of twenty-five years' duration, with a circumference of thirty-nine inches, which weighed thirty-two pounds. Dr. Porter performed amputation of the thigh for long-standing disease of the knee-joint.

Between the operations Dr. Beach showed a patient, aged eighty, from the back of whose hands symmetrical cancer had been removed in April and the resulting wounds entirely healed by means of skin and sponge grafts; a stone one-and-seven-eighths inches by three-and-one-fourth inches, weighing one hundred and ninety grains, removed from a boy of fourteen, and a second stone weighing two hundred and forty grains, from a boy aged eight years. The stone first mentioned was almond-shaped and its appearance suggested the incrustation of some foreign body previously introduced. Upon section and analysis, Professor Wood pointed out the interesting fact that the elongated nucleus was due to a gradual growth upon the end of the stone held by the lower end of the ureter, and as it grew, it was projected forward upon the floor of the bladder in the direction of the internal meatus. The direction of the striæ in the nucleus, which was composed of oxalate of lime, substantiated this theory — afterwards the stone had become enlarged by the deposition of urate of ammonia and phosphates. Both stones were successfully removed by lateral lithotomy; also a recovery from caries of the tarsus in child, after excision of the astragalus and scaphoid.

Dr. Warren exhibited a case of recovery after dislocation of cervical vertebrae, and showed the apparatus for maintaining a gastric fistula in his recent case of gastrotomy for malignant stricture of œsophagus. He also showed the patient upon whom Dr. M. H. Richardson performed gastrotomy for removal of a plate of artificial teeth, a patient whose knee Dr. Richardson had excised in 1886, and a successful case of resection of the musculo-spiral nerve, done a year ago by Dr. Richardson.

NEW YORK.

—The medical bill recently passed by the Legislature has been signed by the Governor.

—A case of hydrophobia at Nyack, on the Hudson, terminated fatally on the 23d. Dr. Wm. A. Hammond saw the patient, who was an adult, in consultation with the Nyack physicians the day before death occurred, and pronounced it undoubtedly genuine rabies.

—Dr. Woolsey Johnson, recently one of the Health Commissioners of the city, died June 21st, of Bright's disease, at the age of forty-five. He was graduated at the College of Physicians and Surgeons in 1863,

and afterwards continued his medical studies at Paris and in Germany. He devoted himself more particularly to diseases of the throat, and was at one time lecturer in this branch at the College of Physicians and Surgeons; while for many years he was a visiting physician to the New York Hospital and the New York Eye and Ear Infirmary. He was very highly esteemed in the community, and was a prominent member of several of the best known New York clubs.

### Correspondence.

#### LETTER FROM BERLIN.

BERLIN, June 13, 1887.

MR. EDITOR.—The Museum of the Pathological Institute of Berlin, has reached proportions which are remarkable. The office of custodian has hitherto fallen to the first assistant of Professor Virchow, and has been quite acceptably filled for the past fourteen years by Dr. Juergens; it has, however, grown to such dimensions as to demand a custodian especially appointed. It has increased from the union of two collections, that belonging to the Charité and a part of the Anatomical Museum of the University. The latter was separated from the Anatomical Museum in 1858, when an independent professor of pathological anatomy was first named. Professor Reichert, who was then director of the Museum, clung to his rights so tenaciously, that it was twelve or sixteen years before the preparations were removed, and then only in part. The entire collection was not removed until after his death. Part of these specimens came down from the earlier years of the last century. Of special worth are the preparations left by Johannes Mueller, constituting as they do, the evidence of his pathological and anatomical work. The Charité collection, which was the ground-work of the Museum, began to assume important proportions in the third decade of the present century. Its originator was Philip Phœbus, who was less known as pathological anatomist than by his labors in pharmacology and through his general usefulness. His industry has left us writings which remain to this day. He is particularly known in his dealing with the regions of the heart. His successor was Robert Frossep. His most important work was not in the field of pathological anatomy, either. Professor Virchow became prospector in 1846, and continued until 1849. The successors of Virchow were his friend Benno Rheinhardt, who, with Professor Virchow, originated the Archives of Pathological Anatomy; and Heinrich Meckel, of Heinsbach. Both died in early life, the victims of consumption. Meckel was the friend of the poet Leneu, who died insane. Meckel examined his brain, and published a carefully prepared report. In 1858, the Museum was again put under Virchow's direction, and it continued to grow until it is one of the first of its kind, both as to the number and worth of its specimens. Pathological anatomy is now the great incentive to a visit to Berlin. Virchow's reputation attracts students and practitioners from every part of the globe; it is true that the man is over-run with politics, the affairs of State, and his many other interests. His lectures can be read as well as heard; he is usually tardy, frequently absent, very cross and irritable, yet he has a great reputation, and men crowd to his lectures.

The University of Berlin has about 2,000 medical students, 6,000 of all kinds. In the medical department there are 44 professors, 37 doctents, and 69 assistants.

Some of the professors of the medical department realize quite snug little sums from their teaching. Suppose, for instance, as is usually the custom, each student pays 50 marks (\$12.00) per semester for his instruction. Say from 150 to 300 take a certain professor's lectures. He then receives \$1,800 to \$3,600 for his six months' work,

which six months, omitting holidays and tardiness in beginning, is reduced to five months. For this, however, he lectures every day or nearly so, sometimes twice in one day, and frequently two hours at a time. The professors depend largely on their teaching, of course, and give it much time and attention. Many students do not pay cash, however. The professor gives to such, time to finish their course, get out into practice, and make the money to pay for their instruction. The student has not enough money to pay for his beer, knipe, duelling expenses, and lectures too, so the latter is deferred. It is considered a debt of honor, though, and payment is seldom avoided. If the man dies and leaves nothing behind, the Professor loses his money. For years afterward, he receives frequent small installments for a former semester's course of lectures.

The students are required to attend nine semesters, four-and-one-half years, before graduating. Examinations are frequent and they do not take up much at a time. There are several professors on each branch, and if a student is expecting to be examined on some department, he can spend almost the entire day in attending clinics and listening to lectures on that subject. The professor examines about four or six at a time, two or three times a week. The examinations are oral and clinical.

Berlin maintains ten medical societies: the Gesellschaft der Charité Aerzte, Dr. M. Molhausen, President; Professor Henoch, Secretary; six members, meets every two weeks. Gesellschaft fuer Geburtshilfe und Gynecologie, Professor Olshausen, President; Dr. A. Martin, Secretary; nine members, meets fortnightly. Gesellschaft fuer Heilkunde, Dr. Cock, Secretary; 165 members, meets annually. Gesellschaft fuer Naturwissenschaft und Heilkunde, Prof. R. Hartmann, President, Dr. Oertels, Secretary; 52 members, meets monthly. Gesellschaft fuer Nervenheilkunde, Prof. Westphal, President, Prof. Bernhardt, Secretary; 92 members, meets monthly. Medicinische Gesellschaft, Prof. R. Virchow, President, Prof. B. Fränkel, Secretary; 652 members, meets weekly. Physiologische Gesellschaft, Prof. Du Bois Reymond, President, Prof. Hirschley, Secretary; 151 members, meets fortnightly. Psychiatrischer Verein, Dr. Lehr, President, Prof. Guttschaft, Secretary; 112 members, meets quarterly. Verein fuer Innere Medicine, Prof. Leyden, President, Prof. Paul Guttman, Secretary; 230 members, meets fortnightly. Vacations and holidays very greatly reduce the annual number of meetings. As will be seen, the Medicinische Gesellschaft is the leading medical society of the city. It meets in a fine large hall with generally 150-300 members present and is a power in the land. This society has a large library for the benefit of its members.

Berlin has 30 hospitals, containing 5,000 beds. Two thousand of these are in the Charité, by far the largest hospital in the city. Berlin has 1,150 physicians, 8.98 per 10,000 inhabitants, 65 dentists, and 88 druggists. Prussia has 9,071, or 8.84 per 10,000 inhabitants, 275 dentists, 2,519 druggists, 1,420 hospitals, with 72,808 beds. Germany has 15,783 physicians, 48 per 10,000, 470 dentists, 4,624 druggists, 2,645 hospitals, with 128,306 beds. While these statistics show the low rate of physicians, as compared with the United States, it gives a large number of hospitals and beds, which makes the difference. So many more in Germany receive free treatment at the hospitals, that there are fewer pay-patients left. Yet I think, with the small number of physicians, they might get on without grumbling. What if they had one physician for every 500 inhabitants, and old women were permitted to practice!

It may be of interest to American physicians to know a few of the legal rates allowed German physicians and surgeons for their work. Remember that a mark is a quarter, or about twenty-three and one-half cents: Light, natural labor, 6-15 marks; twin, 9-24 marks; natural, but tedious labor, day and night, 12-15 marks; foot-presentation, 12-30 marks; turning, 12-36; forceps, 12-30 marks; craniotomy, 30-60; Cesarean section, living woman, child alive or not, 30-60; same, dead woman, 12-24; removal of unripe ovule or mole, 8-12. Examination of pregnant

woman, 1.50-6 marks. Writing a full report of case, 1.55-3 marks.

Surgery: Trephining, 24-36 marks. Strabismus, operation, one eye, 24-45; both eyes, one-half more. Extirpation epithelioma of the lip, 12-24; second operation, one-half as much more. Enucleation of the eye, 12-36 marks; hair-lip, 12-24 marks. Excision of the tonsils, 9-18 marks. Removal of nasal polypus, 18-80 marks. Catheterization, men, 3-6; women, 1.50-3 marks. Foreign body in the oesophagus, 6-12 marks. Tracheotomy, 18-86 marks. Excision of the breast, 24-45 marks. Paracentesis thoracis, 15-20 marks. Circumcision, 6-12 marks. Castration, 30-60 marks. Cut for stone, 60-150 marks. Amputation upper arm and leg, 24-45 marks. Reposition dislocated arm, 9-18 marks. Setting broken collar-bone, 9-16 marks; neck of femur, 12-24 marks. Blood-letting, 2-6 marks. Assistant at operation, 3-9 marks. Post-mortem, 6-12 marks.

Physicians' visits in the city, first two, 4 marks; each successive visit, with prescription, 1-2 marks. Patient

one mile from city, first visit, 6-8 marks; each succeeding visit, 2-8 marks. Contagious fevers, charges doubled. Night visits, first, 6-9 marks; each following, 3-6 marks.

Only two visits daily can be charged for. Prescriptions in office, one-third to three-fourths mark. First consultation, 4.50-9 marks; each succeeding, 2.25-3 marks.

These fees, as may be readily seen, are very low. They are not followed closely, however, but are the legal fees, and are the amounts which may be collected by law. They have been in force since 1815, but usually these rates are exceeded.

As a contrast to these small figures, we may now view some large ones. As nearly as your correspondent could ascertain, Professor Schroeder enjoyed from his practice an income of 250,000 marks annually, Gussow 150,000 marks, Martin, 100,000 marks, while Waldeyer, from his teaching, realizes 25,000 marks yearly. Martin has been known to ask and receive 4,500 marks for an ovariotomy.

M.

## REPORTED MORTALITY FOR THE WEEK ENDING JUNE 18, 1887.

Deaths reported 2,297; under five years of age 975; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 506; consumption 293, acute lung diseases 196, diarrhoeal diseases 256, diphtheria and croup 107, scarlet fever 30, typhoid fever 24, malarial fever 24, measles 24, cerebro-spinal meningitis 16, whooping-cough 14, erysipelas six, puerperal fever four, small-pox (New York) one. From measles New York six, Lowell four, Philadelphia three, Brooklyn, Boston, New Orleans and Cambridge two each, Pittsburgh, Chelsea and, Charleston one each. From typhoid fever, Philadelphia six, New York five, Charleston four, Boston three, Worcester two, Brooklyn, Baltimore, New Orleans, Pittsburgh and Lawrence one each. From malarial fever, Brooklyn seven, New York six, New Orleans five, Baltimore and Nashville, three each. From cerebro-spinal meningitis, New York 11, District of Columbia two, Philadelphia, Boston, Milwaukee one each. From

whooping-cough, New York and Boston, four each, Philadelphia two, District of Columbia and Milwaukee one each. From erysipelas, New York three, Brooklyn, Boston, and Lynn one each. From puerperal fever, District of Columbia two, New York and Philadelphia one each.

In the 28 greater towns of England and Wales, with an estimated population of 9,344,069, for the week ending June 4th, the death-rate was 19.5. Deaths reported 3,432; infants under one year of age 755; acute diseases of the respiratory organs (London) 264, measles 252, whooping-cough 143, scarlet fever 44, diarrhoea 34, diphtheria 26, fever 22.

The death-rates ranged from 12.8 in Derby to 30.5 in Manchester; Birmingham 18.8; Bradford 18.1; Hull 18.3; Leeds 17.5; Leicester 15.3; Liverpool 22.6; London 17.9; Nottingham 20.0; Sheffield 19.3; Sunderland 22.9; Wolverhampton 23.2.

In Edinburgh 20.0; Glasgow 20.4; Dublin 21.4.

The meteorological record for the week ending June 18, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 18, 1887, TO JUNE 24, 1887.

**BARTHOLOMEW, J. H.**, major and surgeon. Granted leave of absence for two months, to take effect about July 5, 1887. S. O. 141, A. G. O., June 20, 1887.

**RICHARD, CHAS.**, captain and assistant surgeon. Sick leave extended two months on surgeon's certificate of disability. S. O. 139, A. G. O., June 17, 1887.

**COCHRAN, JNO. J.**, captain and assistant surgeon. Granted leave of absence for one month. S. O. 143, A. G. O., June 22, 1887.

**BORDEN, W. C.**, first lieutenant and assistant surgeon. Granted leave of absence for one month. S. O. 138, A. G. O., June 16, 1887.

**SUTER, WM. A.**, first lieutenant and assistant surgeon. Designated as medical officer for the Rifle Camp at Creedmoor, N. Y., July 5, 1887. S. O. 124, Division of the Atlantic, June 31, 1887.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING JUNE 25, 1887.

**CLERK, C. J.**, medical inspector. Ordered for examination preliminary to promotion as medical director.

**LUMSDEN, G. P.**, passed assistant surgeon. Ordered to Receive Ship "Franklin," Norfolk, Va.

**HORWITZ, P. J.**, medical director. Permission to leave the United States for six months.

**HARRIS, H. N. T.**, assistant surgeon. Commissioned assistant surgeon in the navy June 13, 1887.

**SPEAR, J. C.**, medical inspector. Detached from Naval Laboratory and granted three months leave.

**BLOODGOOD, DELAVAN**, medical director. Detached from Naval Hospital, Norfolk, Va., and to the Naval Laboratory.

**BRADLEY, MICHAEL**, medical inspector. Ordered to Naval Hospital, Norfolk, Va.

**BEYER, H. G.**, passed assistant surgeon. Remain on present duty until September 1, 1887.

**HERNDON, C. G.**, passed assistant surgeon. Remain on present duty until June 17, 1888.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING JUNE 18, 1887.

**BRATTON, W. D.**, assistant surgeon. To proceed to Seattle, W. T., on special duty, June 8, 1887. When relieved to rejoin station at San Francisco, Cal., June 11, 1887.

**WATKINS, R. B.**, assistant surgeon. Granted leave of absence for thirty days, June 8, 1887.

**HEATH, F. C.**, assistant surgeon. To proceed to Marine Hospital, Detroit, Mich., for temporary duty, June 17, 1887.

#### BOOKS AND PAMPHLETS RECEIVED.

Cornell University. Announcement of the School of Pharmacy for the Year 1887-88.

Annual Report of the Carney Hospital for the Years 1885-86, Boston, 1887.

The Sixty-Third Annual Report of the Officers of the Retreat for the Insane, at Hartford, Conn. April, 1887.

Practical Examples in Prescription Writing. By Charles H. May, M.D. Issued for the Use of his Quiz Classes.

Transactions of the American Gynecological Society, Vol. 11. For the year 1886. New York: D. Appleton & Co., 1887.

Certain Causes of Sterility in the Female and their Treatment. By Egbert H. Grandin, M.D., of New York. (Reprint.)

Electricity and Life: or, the Electro-Vital Theory of Nature. By Edward C. Towne, B.A. Cambridge: Charles W. Sever. 1887.

Notes on the Treatment of Amenorrhoea with Permanganate of Potash. By Thomas A. Ashby, M.D., of Baltimore. Baltimore, 1887. (Reprint.)

Abdominal Surgery, by J. Greig Smith, M.A., F.R.S.E. Surgeon to the Bristol Royal Infirmary, etc. Philadelphia: P. Blakiston Son & Co., 1887.

Pelvic Inflammations: or Cellulitis versus Peritonitis. By Thomas Addis Emmet, M.D., Surgeon to the Woman's Hospital, New York. 1886. (Reprint.)

Iodol: an Effective Substitute for Iodoform. By R. Norris Wolfenden, M.D., Cantab., Senior Physician to the Hospital for diseases of the Throat. Golden Square, London.

A Case of Nephrolithotomy during the Fifth Month of Pregnancy. By Louis McLane Tiffany, M.D., Professor of Surgery in the University of Maryland. 1887. (Reprint.)

First and Second Special Reports upon the Improvement in the Scale of Diet in the Imperial Japanese Navy, for the Seventeenth and Eighteenth Years of Meiji (1884 and 1885).

Transactions of the Eighth Annual Meeting of the American Laryngological Association. Held in the City of Philadelphia, May 27-29, 1886. New York: D. Appleton & Co., 1887.

Congenital Occlusion of the Posterior Nares. By Alvin A. Hubbell, M.D., Buffalo, N. Y., Professor of Diseases of the Eye, Ear, and Throat, in the Medical Department of Niagara University, etc. 1886. (Reprint.)

Some Observations upon the Modern Treatment of Urethritis. By George E. Brewer, M.D., Assistant Surgeon to the Outdoor Department of Roosevelt Hospital. New York: Wm. Wood & Co. 1887. (Reprint.)

The Climatic Treatment of Consumption. A Contribution to Medical Climatology. By James Alex. Lindsay, M.A., M.D., Physician to the Consumptive Hospital, Thronemount, Belfast, etc. London: Macmillan & Co. 1887.

Nasal Reflexes as a Cause of Diseases of the Eye. By W. Cheatham, M.D., Lecturer on Diseases of Eye, Ear, Throat and Nose, University of Louisville; Eye, Ear, Throat and Nose Physician to Louisville City Hospital. 1887. (Reprint.)

A Practical Treatise on Renal Diseases and Urinary Analysis. By William Henry Porter, M.D., Professor of Clinical Medicine and Pathology in the New York Post-Graduate Medical School and Hospital; Curator to the Presbyterian Hospital. One Vol. 100 Illustrations. New York: Wm. Wood & Co.

A Practical Treatise on Obstetrics. Vol. IV. Obstetric Operations. The Pathology of the Puerperium. By A. Charpentier, M.D., Paris. Illustrated with lithographic plates and wood engravings. Being also Volume IV of the "Cyclopaedia of Obstetrics and Gynecology." New York: Wm. Wood & Co.
